**Formation.**—1. From bromo-*m*-xylene and bromo-*p*-xylene by treatment with  $\text{MeI}$  and sodium (Fittig, *A.* 139, 187; 151, 257, 286).—2. From di-bromo-toluene,  $\text{MeI}$ , and sodium (Jannasch, *A.* 176, 286).—3. From phorone (derived from acetone) by treatment with  $\text{P}_2\text{O}_5$  (Jacobsen, *B.* 10, 855).—4. From toluene,  $\text{MeCl}$ , and  $\text{AlCl}_3$  (Friedel & Crafts, *A. Ch.* [6] 1, 461).—5. By boiling pseudo-cumyl-hydrazine with aqueous  $\text{CuSO}_4$  (Haller, *B.* 18, 92).

**Preparation.**—The mixture of  $\psi$ -cumene and mesitylene obtained by the distillation of coal tar is sulphonated by agitation with cold conc.  $\text{H}_2\text{SO}_4$ ; on adding water a portion of the  $\psi$ -cumene sulphonic acid is ppd., the remaining acids are converted successively into their Ba salts, chlorides, and amides, and the latter are separated by crystallisation from alcohol, in which the amide of  $\psi$ -cumene sulphonic acid is sparingly soluble. The sulphonamide is then converted into  $\psi$ -cumene by heating with fuming aqueous  $\text{HCl}$  at 175° (Jacobsen, *B.* 9, 256). The sulphonic acids of  $\psi$ -cumene and mesitylene may also be separated by heating with  $\text{HClAq}$  at 100° for one

hour, when the latter only undergoes hydrolysis (Armstrong, *B.* 11, 1697).  $\psi$ -Cumene sulphonic acid is decomposed by distillation with dilute  $\text{H}_2\text{SO}_4$  in a current of steam, hydrolysis beginning at 115° (Armstrong & Miller, *C. J.* 45, 148).

**Reactions.**—1. Readily attacked by halogens. In the dark 1 mol. of bromine produces mono-(*eso*)-bromo-pseudo-cumene  $\text{C}_9\text{H}_9\text{Br}$  [78°]; further bromination yields di- and tri-(*eso*)-bromo-pseudo-cumene ( $\text{C}_9\text{H}_7\text{Br}_2$  and  $\text{C}_9\text{H}_5\text{Br}_3$ ) of melting-points [61°] and [226°] respectively. Direct *sunshine* acts like *heat*, causing the substitution to take place in the  $\text{CH}_3$  groups; 1 mol. Br produces a liquid  $\omega$ -bromo-(pseudo)-cumene (pseudo-cumyl bromide)  $\text{C}_9\text{H}_9(\text{CH}_2)_2\text{CH}_2\text{Br}$ ; 2 mols. bromine produce  $\omega, \omega'$ -di-bromo-pseudo-cumene  $\text{C}_9\text{H}_7(\text{CH}_2)_2(\text{CH}_2\text{Br})_2$ , which melts at 97° (Schramm, *B.* 19, 216).—2. Converted by boiling with  $\text{AlCl}_3$  into toluene, *m*-xylene, a little *p*-xylene, mesitylene, durene, and isodurene (Anschtütz, *A.* 235, 186).—3. *Methylene chloride* and  $\text{AlCl}_3$  give durene, tetra-methyl-anthracene [c. 163°], hexa-methyl-anthracene [c. 220°] and  $\text{C}_{18}\text{H}_{18}$  [c. 290°] (Friedel & Crafts, *A. Ch.* [6] 11, 263).—4. Gives a tri-nitro-derivative [185°].—5. Dilute  $\text{HNO}_3$  gives two di-methyl-benzoic acids and a little  $\text{C}_9\text{H}_7\text{Me}(\text{CO}_2\text{H})_2$ .

$\psi$ -Cumene hexahydride  $\text{C}_9\text{H}_{12}$  (187°). S.G.  $\frac{2}{4}$  7812;  $\frac{22}{4}$  7667. From  $\psi$ -cumene,  $\text{HI}$ , and  $\text{P}$ .  $\text{HNO}_3$  gives tri-nitro- $\psi$ -cumene. Br and  $\text{AlBr}_3$  give tri-bromo- $\psi$ -cumene (Konovaleff, *C. C.* 1887, 1133). Probably identical with nonaphthene.

Cumene  $\text{C}_9\text{H}_{10}$ , i.e.  $\text{C}_9\text{H}_9\text{Pr}$ . *Isopropyl-benzene*. Mol. w. 120. (153° i.v.). S.G.  $\frac{2}{4}$  8776;  $\frac{22}{4}$  8577 (Silva, *Bl.* [2] 43, 317);  $\frac{2}{4}$  8798;  $\frac{22}{4}$  8587 (Paternò & Pisati, *G.* 3, 574).

**Formation.**—1. By distilling cuminic acid with baryta or lime (Gerhardt & Cahours, *A. Ch.* [3] 1, 87, 372; 14, 107; A. 38, 89; cf. A. 220, 27).—2. From isopropyl bromide, benzene, and  $\text{AlBr}_3$  (Gustavson, *B.* 11, 1251; R. Meyer, *J. pr.* [2] 34, 98). In the same way from *n*-propyl bromide, inasmuch as *n*-propyl bromide is converted by heating with  $\text{AlBr}_3$  into isopropyl-bromide (Kekulé & Schrötter, *B.* 12, 2280).—3. By acting with isopropyl chloride or *n*-propyl chloride on benzene in presence of aluminium chloride (Silva; Claus & Schulte, *B.* 19, 3012).—4. As a by-product by the action of allyl chloride on benzene in presence of  $\text{AlCl}_3$ .—5. By the action of di-chloro-acetone in presence of  $\text{AlCl}_3$  on benzene as a by-product (Silva).—6. From benzylicidene chloride and  $\text{ZnMe}_2$  (Liebmann, *B.* 13, 45).—7. From iso-propyl iodide, bromo-benzene, and sodium (Jacobsen, *B.* 8, 1260).

**Reactions.**—1. *Chromic mixture* gives benzoic acid.—2. Br and  $\text{AlBr}_3$  give  $\text{C}_9\text{H}_7\text{Br}_3$ , isopropyl bromide, and tri-bromo-propane (c. 218°).

Cumene tetrahydride  $\text{C}_9\text{H}_{12}$  (155°). Occurs in small quantity in oil of resin (Renard, *A. Ch.* [6] 1, 239).

Cumene hexahydride  $\text{C}_9\text{H}_{12}$  (c. 149°). S.G.  $\frac{22}{4}$  787. Occurs in oil of resin (Renard, *A. Ch.* [6] 1, 229; cf. Pelletier & Walter, *A. Ch.* [2] 67, 99).

*n*-Cumene  $\text{C}_9\text{H}_{10}\text{Pr}$ . *n*-Propyl-benzene. (158.5°). S.G.  $\frac{2}{4}$  88 (Spica, *G.* 8, 403);  $\frac{22}{4}$  8702 (Schiff). C.E. (9.8 to 158.5°) 001184. V.D. 4.14 (for 4.14). S.V. 161.8 (Schiff, *A.* 220, 98).

**Formation.**—1. From *n*-propyl bromide,

bromo-benzene, and sodium (Fittig, Schäffer a. König, A. 149, 324).—2. From benzyl chloride and  $\text{ZnEt}_2$  (Paternò a. Spica, G. 7, 21).—3. From  $\text{AlCl}_3$ , benzene and allyl chloride (Wispek a. Zuber, A. 218, 378); according to Silva (B. [2] 43, 318) the product is isopropyl-benzene.—4. A product of the action of ethylidene chloride on toluene in presence of  $\text{AlCl}_3$  (Anschütz a. Romig, B. 18, 665).

**Reactions.**—1. In  $\text{CS}_2$  solution it combines with  $\text{CrO}_2\text{Cl}_2$ , forming a chocolate pp.  $\text{PhPr}_2\text{CrO}_2\text{Cl}_2$  converted by water into phenylpropionic aldehyde 4Etard, A. Ch. [5] 22, 252). 2. Chromic mixture gives benzoic acid.—3. By the action of bromine (1 mol.) in the dark or in presence of 3 p.c. of iodine in diffused daylight, a mixture of *o*- and *p*-bromo-propyl-benzene  $\text{C}_6\text{H}_4\text{Br}(\text{C}_2\text{H}_5)$  is obtained. By the action of bromine (1 or 2 mols.) in direct sunshine, the side chain is substituted in the  $\beta$ -position giving  $\text{C}_6\text{H}_5\text{CHBr}\cdot\text{CH}_2\cdot\text{CH}_3$  or  $\text{C}_6\text{H}_5\text{CBr}_2\cdot\text{CH}_2\cdot\text{CH}_3$ . If the  $\beta$ -mono-bromo-propyl-benzene is treated at  $100^\circ$  in the dark with another mol. of bromine,  $\alpha,\beta$ -di-bromo-propyl-benzene is produced  $\text{C}_6\text{H}_5\text{CHBr}\cdot\text{CHBr}\cdot\text{CH}_3$ , [65.5°] (Schramm, B. 18, 1274).

**References.**—BROMO-CUMENE, CHLORO-CUMENE, NITRO-CUMENE, &c. V. also Azo- and HYDRAZO-COMPOUNDS.

**$\psi$ -CUMENE CARBOXYLIC ACID *v.* CUMINIC ACID.**

**$\psi$ -CUMENE-SULPHONIC ACID**  
 $\text{C}_6\text{H}_4\text{Me}_2(\text{SO}_3\text{H})$  [1:3:4:2]. Obtained by debromination of di-bromo-pseudo-cumene-sulphonic acid  $\text{C}_6\text{H}_3\text{Br}_2(\text{SO}_3\text{H})$  [1:3:4:5:6:2] by the action of zinc-dust and aqueous  $\text{NH}_3$  upon the sodium salt. It is formed, together with the isomeride [1:3:4:5] and other products, by the prolonged action of conc.  $\text{H}_2\text{SO}_4$  upon durene (*q.v.*) or its mono-sulphonic acid.— $\text{NaA}'$ : very soluble small flat needles or plates.

**Amide**  $\text{C}_6\text{H}_4\text{Me}_2(\text{SO}_2\text{NH}_2)$  [113°]; small flat needles or plates; *v. e.* sol. alcohol (Jacobsen, B. 19, 1222).

**$\psi$ -Cumene-sulphonic acid**  $\text{C}_6\text{H}_5\text{Me}(\text{SO}_3\text{H})$  [1:3:4:5]. Obtained by debromination of bromo-pseudocumene-sulphonic acid by the action of zinc-dust and aqueous  $\text{NH}_3$  upon the sodium salt (Jacobsen, B. 19, 1218), or by sodium-amalgam (Kelbe a. Pathe, B. 19, 1556). It is formed, together with the isomeride [1:3:4:2] and other products, by the prolonged action of conc.  $\text{H}_2\text{SO}_4$  upon durene (*q.v.*) or its mono-sulphonic acid.

**Salts.**— $\text{NaA}'$ : needles, *v. sol.* hot water.— $\text{KA}'$ : similar to the preceding.— $\text{AgA}'$ : sparingly soluble white plates.— $\text{BaA}'$ : plates, sparingly sol. cold water (K. a. P.).— $\text{BaA}'_2$ : thin prisms; sol. hot water, sl. sol. cold (J.).

**Amide**  $\text{C}_6\text{H}_5\text{Me}(\text{SO}_2\text{NH}_2)$ : [172°] (J.); [179°] (K. a. P.); needles or very small prisms; *v. sol.* alcohol.

**$\psi$ -Cumene sulphonic acid**  $\text{C}_6\text{H}_5\text{Me}_2\text{SO}_3\text{H}$  [1:2:4:5]. [112°]. Formed by dissolving  $\psi$ -cumene in conc.  $\text{H}_2\text{SO}_4$  at  $80^\circ$ , and crystallised from dilute  $\text{H}_2\text{SO}_4$  (Jacobsen, A. 184, 199). Cubes, sl. sol. dilute  $\text{H}_2\text{SO}_4$ . Converted by potash-fusion into  $\text{C}_6\text{H}_5\text{Me}_2(\text{OH})\text{CO}_2\text{H}$ , whence, by distillation with lime, *m*-xylenol  $\text{C}_6\text{H}_4\text{Me}_2(\text{OH})$  [1:3:4] is got. Fusion of the K salt with sodium formate gives  $\text{C}_6\text{H}_5\text{Me}_2\text{CO}_2\text{K}$  (Reuter, B. 11, 29).

Vol. II.

By the action of bromine upon the aqueous solution 76 p.c. is converted into bromo-pseudo-cumene  $\text{C}_6\text{H}_3\text{Me}_2\text{Br}$  [1:2:4:5], the remainder yielding bromo-pseudo-cumene-sulphonic acid  $\text{C}_6\text{H}_3\text{Me}_2\text{Br}\cdot\text{SO}_3\text{H}$  [1:2:4:3:5] (Kelbe a. Pathe, B. 19, 1546).

**Salts.**— $\text{NaA}'$ : transparent plates, loses 44g in the air.— $\text{NaA}'$ : white plates (from conc. solution).— $\text{KA}'$ : sparingly soluble prisms.— $\text{AgA}'$ : sparingly soluble needles.— $\text{BaA}'_2$ : S. 4.5 at  $11.5^\circ$  (J.).— $\text{BaA}'$ : aq (Fittig a. Ernst, A. 139, 188).

**Chloride**  $\text{C}_6\text{H}_4\text{Me}_2\text{SO}_3\text{Cl}$ . [61°]. Monoclinic prisms (from ether).

**Amide**  $\text{C}_6\text{H}_4\text{Me}_2\text{SO}_2\text{NH}_2$ . [176°] (K. a. P.); [181°] (Jacobsen, B. 19, 2518). S. 0.14 at  $0^\circ$ ; 26 at  $100^\circ$ . Large prisms, sol. hot, sl. sol. cold alcohol. Conc.  $\text{HCl}$  at  $176^\circ$  splits it up into  $\text{NH}_3$ ,  $\text{H}_2\text{SO}_4$ , and  $\psi$ -cumene. Potassium permanganate gives  $\text{C}_6\text{H}_4(\text{CO}_2\text{H})\text{Me}_2(\text{SO}_2\text{NH}_2)$  [1:2:4:5],  $\text{C}_6\text{H}_4(\text{CO}_2\text{H})\text{Me}(\text{SO}_2\text{NH}_2)$  [1:4:2:5], and finally  $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_2(\text{SO}_2\text{NH}_2)$  (Jacobsen a. H. Meyer, B. 16, 190). By heating with a small quantity of  $\text{HCl}$  there is formed  $\text{C}_6\text{H}_4\text{Me}_2\text{SO}_3\text{NH}$  [177°], which is soluble in alkalis.

**Cumene-( $\alpha$ )-sulphonic acid**  $\text{C}_6\text{H}_5(\text{C}_2\text{H}_5)\text{SO}_3\text{H}$ . **Isopropyl-benzene sulphonic acid**. Formed in largest quantity by sulphonating cumene in the cold. By warming to  $100^\circ$ , or by several weeks' standing with the excess of  $\text{H}_2\text{SO}_4$  it is in great part converted into the ( $\beta$ )-acid (Claus a. Tonn, B. 18, 1239). Small deliquescent scales. Potassium permanganate in presence of KOH forms  $(\text{CH}_3)_2\text{C}(\text{OH})\cdot\text{C}_6\text{H}_4\cdot\text{SO}_3\text{H}$  (R. Meyer, A. 219, 300).

**Salts.**— $\text{KA}'$ .— $\text{BaA}'_2$ : aq; laminae. S. 4.6 at  $16^\circ$ , 5.6 at  $60^\circ$ , 50 at  $100^\circ$ .— $\text{PbA}'_2$ : aq; pearly scales.— $\text{CaA}'_2$ , 2aq.— $\text{SrA}'_2$ , 2aq. S. 100. On heating the solution saturated in the cold to  $100^\circ$  a crystalline pp. of  $\text{BrA}'_2$  is formed.— $\text{MgA}'_2$ , 7aq.— $\text{AgA}'$ .

**Amide**  $\text{C}_6\text{H}_5\text{Pr}\cdot\text{SO}_2\text{NH}_2$ . [108°] (M.; Spica, G. 9, 433); [112°] (C. a. T.). Converted into *p*-oxy-benzoic acid by treatment with  $\text{KMnO}_4$  and fusion of the product with potash.

**Cumene-( $\beta$ )-sulphonic acid**  $\text{C}_6\text{H}_5(\text{C}_2\text{H}_5)\text{SO}_3\text{H}$ . Formed, together with a smaller quantity of the ( $\alpha$ )-sulphonic acid, by heating cumene with an excess of ordinary  $\text{H}_2\text{SO}_4$  on the water-bath (Claus a. Tonn, B. 18, 1239; Spica, G. 9, 433). Small needles. *V. sol.* water. By fusion with sodium formate it is converted into a cuminic acid which gives phthalic acid on oxidation (Claus a. Schulte, B. 19, 3012).

**Salts.**— $\text{A}'_2\text{Ba}_3$  4aq: small needles; S. 20 at  $16^\circ$ ; more soluble than the Ba salt of the preceding acid.— $\text{A}'_2\text{Pb}$  2aq: easily soluble microscopic needles.— $\text{A}'_2\text{Mg}$  8aq: soluble pearly plates.— $\text{A}'_2\text{Zn}$  7aq: easily soluble glistening needles.— $\text{A}'_2\text{Cu}$  8aq: easily soluble large green needles.

**Chloride**  $\text{C}_6\text{H}_{11}\text{SO}_3\text{Cl}$ : yellow oil.

**Amide**  $\text{C}_6\text{H}_{11}\text{SO}_2\text{NH}_2$ : [127° uncor.] (C. a. T.); [96°] (S.); glistening needles.

***n*-Cumene sulphonic acid**  $\text{C}_6\text{H}_5\text{Pr}\cdot\text{SO}_3\text{H}$ . Formed from *n*-cumene and  $\text{H}_2\text{SO}_4$ . According to Paternò a. Spica (G. 8, 408) both the *o* and *p* acids are formed.

**Salts.**— $\text{KA}'$  4aq (from alcohol).— $\text{CaA}'_2$ .— $\text{BaA}'_2$  (Fittig, A. 149, 330).

**Amide**  $\text{C}_6\text{H}_5\text{Pr}\cdot\text{SO}_2\text{NH}_2$ . [110°]. Scales (from water) (R. Meyer, A. 219, 29°).

U

$\psi$ -CUMENOL  $C_6H_5(CH_3)_2OH$  [5:4:2:1]. [72°]. (235°). H.F. p. 68,540 (Stohmann, *J. pr.* [2] 84, 818).

**Formation.**—1. Formed by diazotising  $\psi$ -cumidine [62°] and boiling the diazo-compound with water (Liebmann a. Kostanecki, *B.* 17, 885; Auwers, *B.* 17, 2976; Krohn, *B.* 21, 884). 2. By fusing  $\psi$ -cumene sulphonic acid with KOH (Reuter, *B.* 11, 29).

**Properties.**—Slender flexible needles, very volatile with steam. Insol. cold water.  $FeCl_3$  does not colour its solutions. Gives a bromo-derivative [32°] and a di-bromo-derivative [150°].

**Benzoyl derivative**  $C_6H_5Me_2(OBz)$ . [63°]. H.F. 87,240 (Stohmann, *J. pr.* [2] 36, 8).

**Methyl ether**  $C_6H_5(CH_3)_2OMe$ . (214°) (H.); (211°) (Auwers, *B.* 18, 2657); colourless liquid. Formed by heating sulphate of diazo-pseudo-cumene with methyl-alcohol (Hofmann, *B.* 17, 1918).

**Ethyl ether**  $C_6H_5(CH_3)_2OEt$ : (224°); colourless liquid. Formed by heating sulphate of diazo-pseudo-cumene with ethyl-alcohol.

**Isoamyl ether**  $C_6H_5(CH_3)_2OC_4H_9$ : (265°).

**Sulphate**  $C_6H_5Me_2(OSO_3H)$ . From  $\psi$ -cumene and  $H_2SO_4$  (Reuter, *B.* 11, 29). Small crystals; decomposed by water into  $\psi$ -cumene and  $H_2SO_4$ , even in the cold.— $BaA'$ : slightly soluble leaflets.— $KA'$ — $ZnA'$ .

$\psi$ -Cumeneol  $C_6H_5Me_2(OH)$  [1:3:4:2]. [62°]. (235°). Formed from pseudo-cumene-sulphonic acid (1:3:4:2) by KOH fusion (Jacobsen, *B.* 19, 1223). Long needles (from ether).  $FeCl_3$  gives no colouration.

$\psi$ -Cumeneol  $C_6H_5Me_2(OH)$ . [95°]. (231° i.v.). From the corresponding cumidine [36°] by diazo-reaction (Edler, *B.* 18, 630). Formed also by fusing the corresponding sulphonic acid with potash (Jacobsen, *B.* 19, 1219). Long prisms. Gives no colour with  $FeCl_3$ . It gives a di-bromo-derivative [152°].

$\psi$ -Cumeneol  $C_6H_5Me_2(OH)$ . (217°). From the diazo-compound of  $\psi$ -cumidine (224°) by boiling with dilute  $H_2SO_4$  (Engel, *B.* 18, 2230). Oil. Gives no colouration with  $FeCl_3$ .

*o*-Cumeneol  $C_6H_5Pr.OH$ . *o*-Isopropyl-phenol. [15°]. (212° i.v.). S.G.  $\frac{2}{3}$  1.0124. From *o*-cumidine by displacing  $NH_2$  by  $OH$  through the diazo-reaction (Fileti, *G.* 16, 113). Formed also by potash-fusion from cumene *o*-sulphonic acid (Spica, *G.* 9, 433). Its aqueous solution is coloured violet by  $FeCl_3$ . It gives a bromo- and a tri-nitro-derivative. Sodium and  $CO_2$  gives cumenol carboxylic acid and di-oxy-di-isopropyl-diphenyl-carboxylic acid.  $PBr_3$  gives bromo-cumene and  $(C_6H_5Pr.O)_2PO$  (c. 378 at 280 mm.), whence alcoholic KOH forms  $(C_6H_5Pr.O)_2(HO)PO$ .

**Acetyl derivative**  $C_6H_5Pr.OAc$ . (229°). S.G. 1.03. Liquid, decomposed by prolonged boiling with water.

**Methyl ether**  $C_6H_5Pr.OMe$ . (193° cor.). **Ethyl ether**  $C_6H_5Pr.OEt$ . (209° cor.). S.G.  $\frac{2}{3}$  9444.

*p*-Cumeneol  $C_6H_5Pr(OH)$  [1:4]. [61°]. (229° cor.). From cumene *p*-sulphonic acid by potash-fusion (Paternò a. Spica, *G.* 6, 535). Formed also by heating  $C_6H_5(CO_2H)Pr(OH)$  [1:3:6] with conc.  $HCl$  at 180° (Jesurun, *B.* 19, 1416).  $FeCl_3$  colours the alcoholic solution green.

**Acetyl derivative**  $C_6H_5Pr.OAc$ . (244° cor.). S.G.  $\frac{2}{3}$  1.026.

**Methyl ether**  $C_6H_5Pr.OMe$ . (218° cor.). S.G.  $\frac{2}{3}$  962.

**Ethyl ether**  $C_6H_5Pr.OEt$ . (245°). S.G.  $\frac{2}{3}$  1.026.

*o-n*-Cumeneol  $C_6H_5Pr(OH)$  [1:2]. *o*-Propyl-phenol. (c. 225° cor.). S.G.  $\frac{2}{3}$  1.015. From allyl iodide and phenol in presence of zinc and aluminium foil (P. F. Frankland a. T. Turner, *C. J.* 43, 358):  $C_6H_5OH + C_3H_7I = HI + C_6H_5C_3H_7OH$  and  $C_6H_5C_3H_7OH + 2HI = C_6H_5C_3H_7OH + I_2$ . Formed also by fusing the corresponding sulphonic acid with potash (Spica, *G.* 8, 418). Liquid; its aqueous solution is turned violet by  $FeCl_3$ .  $CO_2$  acting on its sodium derivative at 140° gives *o*-oxy-propyl-benzoic acid.

**Methyl ether**  $C_6H_5Pr.OMe$ . (208° cor.). S.G.  $\frac{2}{3}$  9694.

*m-n*-Cumeneol  $C_6H_5Pr(OH)$  [1:3]. [26°]. (228° i.v.). From *oxy-n*-cuminic acid and conc.  $HCl$  at 190° (Jacobsen, *B.* 11, 1062). Crystals, v. sl. sol. water.  $FeCl_3$  colours its alcoholic solution green.

*p-n*-Cumeneol  $C_6H_5Pr(OH)$  [1:4]. (231° cor.). S.G.  $\frac{2}{3}$  1.009. Formed by fusing the corresponding *n*-cumene sulphonic acid with potash (Spica, *G.* 8, 411). Formed also by diazotising amido-propyl-benzene and boiling the product with water (Louis, *B.* 16, 100). Oil. Sl. sol. cold water, v. sol. alcohol and ether.  $FeCl_3$  gives at first a violet and then a permanent green colouration.  $CO_2$  on the Na derivative gives *p*-oxy-*n*-cuminic acid.

**Acetyl derivative**  $C_6H_5Pr(OAc)$ . (243° cor.). S.G.  $\frac{2}{3}$  1.029;  $\frac{100}{100}$  942.

**Methyl ether**  $C_6H_5Pr(OMe)$ . (215° cor.). S.G.  $\frac{2}{3}$  964;  $\frac{100}{100}$  912. Yields anisic acid on oxidation.

The same ether appears to be formed, together with anisole, by the action of boron-fluoride on anethol (Landolph, *B.* 13, 145).

Isomerides of cumeneol v. MESITOL and HEMI-MELLITHOL.

Derivatives of cumeneol v. AMIDO-CUMENOL, BROMO-CUMENOL, NITRO-CUMENOL, &c.

Di-cumeneol v. DI-OXY-DI-CUMYL.

CUMENOL-CARBOXYLIC ACID v. OXY-CUMINIC ACID.

CUMENOL SULPHONIC ACID  
 $C_6H_5Pr(OH)(SO_3H)$ . From cumeneol and  $H_2SO_4$  (Jacobsen, *B.* 11, 1062). The Ba salt forms crystalline crusts. Its solution is coloured violet by  $FeCl_3$ .

CUMENYL. A name sometimes applied to the radicle cumyl  $C_6H_5$ .

CUMENYL-ACRYLIC ACID v. CUMYL-ACRYLIC ACID.

CUMIC v. CUMINIC.

CUMIDIC ACID v. XYLENE DICARBOXYLIC ACID.  
*o*-CUMIDINE  $C_6H_5N$  i.e.  $C_6H_5Pr(NH_2)$  [1:2]. (215°). Formed by distilling amido-cuminic acid with baryta (Fileti, *G.* 13, 379). Formed also, together with the following, by nitrating cumene and reducing the product (Constam a. Goldschmidt, *B.* 21, 1157). Converted by passing over red-hot  $PbO$  into indole.

Salts.— $BHCl$ : large prisms.— $BH_2C_2O_4$ : [173]; long prisms.

**Acetyl derivative**  $C_6H_5NHAc$ . [72°]. Tufts of needles.

*p*-Cumidine  $C_6H_5Pr(NH_2)$  [1:4]. (225°) (N.); (219°) (C. a. G.). S.G. 953. Formed by reducing

**nitro-cumene** (from cuminic acid) (Nicholson, A. 66, 58). From aniline, isopropyl alcohol, and  $\text{ZnCl}_2$  at  $270^\circ$  (Louis, B. 16, 111). May be solidified by cold. —  $\text{B'HCl}$ . —  $\text{B}'_2\text{H}_4\text{PtCl}_6$ . —  $\text{B'HNO}_3$ . —  $\text{B}'_2\text{H}_4\text{SO}_4$ . —  $\text{B}'_2\text{C}_2\text{N}_2$ : long needles (Hofmann, A. 66, 145). Oxalate  $\text{B}'_2\text{H}_4\text{C}_2\text{O}_4$  2aq: [189°] (Constan a. Goldschmidt, B. 21, 1157).

**Acetyl derivative**  $\text{C}_9\text{H}_7\text{NHAc}$  [102°].

**$\psi$ -Cumidine**  $\text{C}_9\text{H}_7\text{Me}_2(\text{NH}_2)$  [1:3:4:5]. [36°]. Formed by reduction of nitro-(pseudo)-cumene [20°] (Edler, B. 18, 630). Colourless crystals. Easily volatile with steam.

**Salts.** —  $\text{B'HCl}$ : fine felted needles. —  $\text{B'HNO}_3$ : small glistening plates. The oxalate and sulphate are sparingly soluble in cold water.

**Acetyl derivative** [194°]; long prisms; nearly insol. ether.

**$\psi$ -Cumidine**  $\text{C}_9\text{H}_7\text{Me}_2(\text{NH}_2)$  [1:2:4:5]. [68°] (Auwers, B. 18, 2661); [63°] (H.). (235°). Crystalline solid.

**Formation.** — 1. Occurs in the crude cumidine obtained by heating xylylidine hydrochloride with methyl alcohol at a high temperature under pressure (Hofmann a. Martius, B. 4, 747; 13, 1730; Hofmann, B. 15, 2895; cf. Nölting a. Forel, B. 18, 2680). — 2. By nitration and reduction of pseudocumene (Schaper, Z. 1867, 13). Large prisms. Nitrous acid converts it into  $\text{C}_9\text{H}_7\text{Me}_2\text{N}_2\text{C}_6\text{H}_4\text{Me}_2(\text{NH}_2)$ , whence may be obtained  $\text{C}_9\text{H}_7\text{Me}_2\text{N}_2\text{C}_6\text{H}_4\text{HMe}_2\text{N}_2$  [124°],  $\text{C}_9\text{H}_7\text{Me}_2\text{N}_2\text{C}_6\text{H}_4\text{HMe}_2\text{N}_2$  [91°].

$\text{C}_9\text{H}_7\text{Me}_2\text{N} \xrightarrow{\text{N}} \text{C}_9\text{H}_7\text{HMe}_2$  [85°] and

$\text{C}_9\text{H}_7\text{Me}_2\text{N}_2\text{C}_6\text{H}_4\text{HMe}_2\text{N}_2\text{H}$  [153°] (Zincke a. Jaeneke, B. 21, 516).

**Salts.** —  $\text{B'HCl}$ : thick prisms, sol. water, sl. sol. dilute  $\text{HCl}$ . —  $\text{B}'_2\text{H}_4\text{Cl}_2\text{PtCl}_6$ : fine needles, decomposed by boiling water (De Coninck, Bl. [2] 46, 131). —  $\text{B}'_2\text{H}_4\text{SnCl}_4$ : laminae. —  $\text{B}'_2\text{H}_4\text{PO}_4$  (Lewy, B. 19, 2729).

**Acetyl derivative**  $\text{C}_9\text{H}_7\text{Me}_2\text{NHAc}$ : [164°]; (360°); thick white needles; v. sol. alcohol and acetic acid, insol. water (Auwers, B. 18, 2661; cf. Nölting a. Baumann, B. 18, 1145).

**Formyl derivative**  $\text{C}_9\text{H}_7\text{Me}_2\text{NH.CO.H}$ : [121°]; colourless prisms; v. sol. alcohol and ether, nearly insol. water.

**Thioformyl derivative**

$\text{C}_9\text{H}_7\text{Me}_2\text{NH.CS.H}$ . Formed by heating the formyl derivative with  $\text{P}_2\text{S}_5$  (Senior, B. 18, 2296).

**$\psi$ -Cumidine**  $\text{C}_9\text{H}_7\text{Me}_2\text{NH}_2$  (224°).

**Preparation.** — The solid hydrochloride obtained by adding conc.  $\text{HCl}$  to crude com. cumidine is basified with  $\text{NaOH}$  and fractionated. The fraction c.  $225^\circ$ – $227^\circ$  is boiled with acetic acid for twelve hours, and the product crystallised from alcohol; a small quantity of acetylmesidine crystallises out, and the mother-liquors contain the acetyl derivative of the new cumidine, which is obtained pure by several crystallisations from water, and finally converted into the base by saponification with solid  $\text{KOH}$ .

**Salts.** —  $\text{B'HCl}$ : white needles; v. sol. water, nearly insol. conc.  $\text{HCl}$ . The platino-chloride is sol. water, sl. sol. alcohol. The nitrate is less soluble than the sulphate.

**Acetyl derivative**  $\text{C}_9\text{H}_7\text{Me}_2\text{NHAc}$ : 112°; crystalline solid (Engel, B. 18, 2229).

**Cumidine**  $\text{C}_9\text{H}_7\text{Me}_2(\text{NH}_2)$  [1:2:3:4]? **Hemilithidine?** **Amido-c-tri-methyl-benzene** 240°. From *o*-xylylidine hydrochloride and

$\text{MeOH}$  at  $310^\circ$  (Nölting a. Forel, B. 18, 2680). Liquid.

**Acetyl derivative**  $\text{C}_9\text{H}_7\text{Me}_2(\text{NHAc})$ . [above 180°].

**$\psi$ -Cumidine**  $\text{C}_9\text{H}_7\text{Me}_2\text{NH}_2$  [1:3:4:2]. (236° uncor.). Liquid at  $-15^\circ$ . Obtained from nitro- $\psi$ -cumidine (from tri-nitro- $\psi$ -cumene) by elimination of the  $\text{NH}_2$  group by the diazo-reaction and reduction of the nitro- $\psi$ -cumene [30°], which is obtained with  $\text{SnCl}_2$  (Mayer, B. 20, 971). Probably identical with the  $\psi$ -cumidine obtained by Nölting and Forel (B. 18, 2680) by nuclear methylation of the *o*-xylylidine  $\text{C}_9\text{H}_7\text{Me}_2\text{NH}_2$  [2:3:1].

**Acetyl derivative**  $\text{C}_9\text{H}_7\text{Me}_2(\text{NHAc})$ . [186°].

***n*-Cumidine v. AMIDO-PHENYL-PROPANE**, vol. i. p. 179.

**Isomeride of cumidine v. PHENYL-PROPYL AMINE.**

**CUMILIC ACID**  $\text{C}_{10}\text{H}_{10}\text{O}_2$ , i.e.  $(\text{C}_6\text{H}_4(\text{C}_6\text{H}_5))_2\text{C}(\text{OH}).\text{CO}_2\text{H}$ ? [120°]. Prepared by fusion of cumilin with  $\text{KOH}$ ; yield 70 p.c. (Bösler, B. 14, 326). Fine white needles. Sol. alcohol, ether, and benzene, sl. sol. water.

**CUMINAL-ACETONE v. METHYL-PROPYL-STYRYL KETONE.**

**Di-cuminal-acetone v. DI-PROPYL-DI-STYRYL KETONE.**

**CUMINDIGO v. DI-ISOPROPYL-INDIGO.**

**CUMINIC ALCOHOL v. CUMINYL ALCOHOL.**

***o*-n-CUMINIC ACID**  $\text{C}_{10}\text{H}_{10}\text{O}_2$ , i.e.

$\text{C}_6\text{H}_4\text{Pr}(\text{CO}_2\text{H})$  [12]. ***o*-*n*-Propyl-benzoic acid**. Mol. w. 164. [58°]. From phthalyl-propionic acid, conc.  $\text{HIAq}$  (10 pts.), and red phosphorus (1 pt.) (Gabriel a. Michael, B. 11, 1014). Slender leaflets.

***p*-*n*-Cuminic acid**  $\text{C}_6\text{H}_4\text{Pr}(\text{CO}_2\text{H})$  [14]. ***p*-*n*-Propyl-benzoic acid** [140°].

**Formation.** — 1. From *p*-bromo-*n*-propylbenzene, sodium, and  $\text{CO}_2$  (R. Meyer, J. pr. [2] 34, 102). — 2. From  $\text{C}_6\text{H}_4\text{PrPr}$  by oxidation (Paternò a. Spica, B. 10, 1746). — 3. From  $\text{C}_6\text{H}_4\text{Pr}$ , and dilute  $\text{HNO}_3$  (H. Körner, A. 216, 228).

**Properties.** — Laminae (from water) or needles (from dilute alcohol). Sl. sol. boiling water. Volatile with steam.  $\text{KMnO}_4$  gives terephthalic acid.

**Salts.** —  $\text{CaA}$ , 3aq: slender satiny needles. —  $\text{SrA}$ , 2½aq. —  $\text{BaA}$ , 2aq. —  $\text{PbA}$ , 2aq. —  $\text{AgA}$ .

**Nitrile**  $\text{C}_6\text{H}_4\text{Pr.CN}$  [227°]. From *p*-propylphenyl thiocarbimide and copper powder at  $220^\circ$  (Franksen, B. 17, 1229). Liquid. Saponified by conc.  $\text{HClAq}$  at  $200^\circ$ .

***o*-Cuminic acid**  $\text{C}_6\text{H}_4\text{Pr.CO}_2\text{H}$  [1:2]. Formed by fusing a salt of cumene-( $\beta$ )-sulphonic acid with an excess of sodium formate; the yield is 10 p.c. Sublimable. Volatile with steam. V. sol. alcohol, ether, &c., insol. cold water. Oxidation with  $\text{KMnO}_4$  gives *o*-phthalic acid. Its alkaline salts are excessively soluble. —  $\text{A}$ ,  $\text{Ca}$  2aq: small soluble needles. —  $\text{A}$ ,  $\text{Ba}$  2aq: soluble needles. —  $\text{A}$ ,  $\text{Mg}$  6aq: very soluble needles. —  $\text{A}$ ,  $\text{Pb}$  aq: very sparingly soluble white powder. —  $\text{A}$ ,  $\text{Cu}$  2½aq: very sparingly soluble blue-green amorphous pp.

**Chloride**  $\text{C}_6\text{H}_4\text{Pr.COCl}$ : yellowish oil, v. sol. ether and chloroform.

**Amide**  $\text{C}_6\text{H}_4\text{Pr.CO.NH}_2$ : [124° uncor.]; small needles; v. sol. alcohol and ether, v. sl. sol. water (Claus a. Schulte im Hof, B. 19, 3013).

*p*-Iso-cuminic acid  $C_9H_7Pr(CO_2H)$  [1:4]. [117°] (M.). H.C.v. 1,239,000 (Berthelot a. Louguine, *A. Ch.* [3] 13, 358).

**Formation.**—1. From bromo-iso-propyl-benzene, Na, and CO (R. Meyer, *J. pr.* [2] 34, 100).—2. By the oxidation of cuminic aldehyde or oil of cumim (Gerhardt a. Cahours, *A. Ch.* [3] 1, 70; Beilstein a. Kupffer, *B.* 6, 1184; *A.* 170, 302; Lippmann a. Lange, *B.* 13, 1600; Meyer, *A.* 219, 244).—3. Cymene when taken internally passes into the urine as cuminic acid (Nencki a. Ziegler, *B.* 5, 749; cf. Hofmann, *A.* 74, 342).

**Properties.**—From water (3 pts.) and alcohol (1 pt.) it separates in trichloric needles:  $\alpha:b:c = 6742:1:8072$ ;  $\alpha = 86^\circ 55'$ ,  $\beta = 101^\circ 12'$ ,  $\gamma = 106^\circ 55'$  (Groth; cf. Panebianco, *G.* 10, 81). *v.* sl. sol. cold water, *v.* sol. alcohol and ether. Converted into cumene by distillation over lime. Chromic mixture oxidises it to terephthalic acid.  $KMnO_4$  forms, as an intermediate product, oxy-propyl-benzoic acid  $(CH_3)_2C(OH).C_6H_4.CO_2H$  (Meyer).

**Salts.**— $BaA'$ , 2aq: laminae. *S.* -996 at  $20.5^\circ$ .— $CaA'$ , 5aq: needles. *S.* -81 at  $20.5^\circ$ .— $MgA'$ , 6aq: laminae. *S.* -825 at  $20.5^\circ$ .— $AgA'$ .

*Ethyl ether EtA'*. (240°). *V.D.* 6.65.

*Phenyl ether Pha'*. [58°]. From potassium-phenol and the chloride of the acid (Williamson a. Scrugham, *Pr.* 7, 18). Also formed by distilling cuminylic salicylic acid (Kraut, *J.* 1858, 406; *Ar. Ph.* [2] 96, 271).

*Eugenylether*  $C_6H_5(C_6H_4)(OMe)A'$ . Tables (Cahours, *A.* 108, 323; *A. Ch.* [3] 41, 491).

*Anhydride*  $(C_9H_7Pr.CO)_2O$ . Oil (Gerhardt, *A.* 87, 77; *A. Ch.* [3] 37, 304).

*Peroxide*  $(C_9H_7Pr.CO)_2O_2$ . Needles (from ether). Explodes when heated (Brodie, *P.* 121, 372; *Pr.* 12, 655).

*Chloride*  $C_9H_7Pr.COCl$ . (257°). *S.G.* 1.07. Liquid (Cahours, *A.* 70, 45; *A. Ch.* [3] 23, 347).

*Amide*  $C_9H_7Pr.CONH_2$ . [154°] (F.); [o. 157°] (G.). **Formation.**—1. By heating ammonium cuminate (Field, *A.* 65, 49).—2. From the nitrile and alcoholic KOH.—3. From the anhydride and  $NH_3$  (Gerhardt, *A.* 87, 167).—4. By heating cuminic acid (164 g.) with potassium sulphocyanide (50 g.) for 5 hours with inverted condenser at  $240^\circ$ , and then for 1 hour at  $300^\circ$ . The nitrile is formed at the same time (Fileti, *G.* 16, 281).—5. By the action of chloroformamide  $OC(NH_2)Cl$  upon cumene in presence of  $Al_2Cl_3$  (Gattermann a. Schmidt, *A.* 244, 54; *B.* 20, 860). **Properties.**—Biaxial crystals, insol. cold water, sl. sol. ether, *v.* sol. alcohol and hot benzene. When boiled with water and yellow HgO it forms  $(C_9H_7Pr.CONH)_2Hg$  13aq, which crystallises in needles [190°].

*Antile*  $C_9H_7Pr.CONHPh$ . Long satiny needles (from alcohol). Sl. sol. alcohol (Cahours, *A. Ch.* [3] 23, 349).

**Benzene sulphamide**  $C_9H_7Pr.CO.NH.SO_2Ph$ . [161°]. From cuminylic chloride and the amide of benzene sulphonic acid (Gerhardt a. Chiozza, *A. Ch.* [3] 46, 151). Prisms.  $AgNO_3$  and a little  $NH_3$  give needles of  $C_9H_7Pr.CO.Na.SO_2Ph$ , which forms a crystalline compound with  $NH_3$  (1 mol.). The benzoyl derivative  $C_9H_7Pr.CO.NBz.SO_2Ph$  is formed as a crystalline mass by treating  $AgNBz.SO_2Ph$  with cuminylic chloride.

*o*-Oxy-benzamide  $C_9H_7Pr.CO.NH.CO.C_6H_4.OH$ . From salicylamide and cuminylic chloride. Needles.

*Nitrile*  $C_9H_7Pr.ON$ . (244° i.v.). *S.G.* 1.765. Formed by heating the amide (Field, *Mem. Chem. Soc.* 3, 408; *A.* 65, 51), or by heating cuminic acid (2 mols.) with  $KCyS$  (1 mol.) (Letts, *B.* 5, 674; Fileti, *G.* 16, 282). Formed also by treating potassium cuminate with  $CyBr$  (Cahours, *A. Ch.* [3] 52, 201; *A.* 108, 326).

Liquid, sl. sol. water, *v.* e. sol. alcohol and ether.

$\psi$ -Cuminic acid  $C_9H_7Me_2(CO_2H)$  [1:2:4:5].

*Durylic acid. Tri-methyl-benzoic acid.* [149°].

**Formation.**—1. By boiling durenene with dilute  $HNO_3$  (Jannasch, *Z.* 1870, 449) or with the calculated quantity of  $CrO_3$  in  $HOAc$  (Gissmann, *A.* 216, 205).—2. By fusing potassium  $\psi$ -cumene sulphate with sodium formate (Reuter, *B.* 11, 31).—3. From the nitrile (Nef, *A.* 237, 9).—4. By hydrolysis of its amide (*cf. infra*).

**Preparation.**—Durenene is boiled for 4 hours with dilute  $HNO_3$  (1 vol. of  $HNO_3$  1:4 *S.G.*) to 3 vols. water. The product is filtered off, extracted with  $Na_2CO_3$ , and the solution precipitated with  $HCl$ . The crude acid is filtered off, treated with tin and  $HCl$  to remove nitro-compounds, and distilled with steam. The yield is 40–50 p.c. of the durenene (Nef, *B.* 18, 2801).

**Properties.**—Needles (from benzene). *V.* sl. sol. boiling water, *v.* e. sol. alcohol and ether. Volatile with steam.

**Salts.**— $CaA'$ , 2aq.— $BaA'$ , 7aq: prisms.

*Amide*  $C_9H_7Me_2.CONH_2$ . [201°]. From  $\psi$ -cumene and chloroformamide  $Cl.CONH_2$  in presence of  $Al_2Cl_3$  (Gattermann, *A.* 244, 54). Needles (from dilute alcohol).

*Nitrile* [58°]. (250°). Formed by the action of  $CuSO_4$  and  $KCN$  upon diazo-pseudo-cumene (Haller, *B.* 18, 93). Long colourless needles. *V.* sol. alcohol, ether, benzene, and ligroin, insol. water.

(a)-Cuminic acid  $C_9H_7Me_2(CO_2H)$  [1:2:3:5]. [216°]. (a)-*Isodurylic acid*. Formed together with the (b) and (γ) isomerides by oxidation of isodurenene with  $HNO_3$ . Distillation with lime yields hemimellitrol. —  $A'$ ,  $Ba$  2aq: long fine needles. —  $A'$ ,  $Ca$  5aq (Jacobsen, *B.* 15, 1855; Bielefeldt, *A.* 198, 384).

(b)-Cuminic acid  $C_9H_7Me_2(CO_2H)$  [1:3:5:2]. (b)-*Isodurylic acid. Mesitylene carboxylic acid*. [151°]. Formed together with the (a) and (γ) isomerides by oxidation of iso-durenene with  $HNO_3$  (Jacobsen, *B.* 15, 1855). Distills without decomposition. Thick glistening prisms. On distillation with lime it gives mesitylene.  $CaA'$ , 2aq: microscopic needles.

(γ)-Cuminic acid  $C_9H_7Me_2(CO_2H)$  [1:2:4:6].  $\psi$ -Cumene carboxylic acid. (γ)-*Isodurylic acid*. [85°]. Formed together with the (a) and (b) isomerides by oxidation of isodurenene with  $HNO_3$  (Jacobsen, *B.* 15, 1855). Distills without decomposition. Volatile with steam. Needles. Sol. alcohol, ether, and hot water, nearly insol. cold water. On distillation with lime it gives pseudo-cumene.

**Salts.**— $A'K'$ : extremely soluble amorphous solid. —  $A'Ba'$ : uncrystallisable. —  $A'Ca$  2aq: microscopic needles.

*c*-Cuminic acid  $C_9H_7Me_2(CO_2H)$  [1:2:3:4]. *Tri-methyl-benzoic acid*. [168°]. Formed by oxidation of the consecutive tetra-methyl-benzenes

(prohnitene) by boiling for 12 hours with dilute  $\text{HNO}_3$ . Long glistening prisms.  $\bullet$  V. e. sol. hot alcohol. Volatile with steam. By distillation with lime it yields the consecutive tri-methyl benzene (hemimellitene) (Jacobsen, B. 19, 1214).

**References.**—AMIDO-CUMINIC ACID, BROMO-CUMINIC ACID, NITRO-CUMINIC ACID, OXY-CUMINIC ACID.

**CUMINIC ALDEHYDE**  $\text{C}_9\text{H}_{10}\text{O}$  i.e.  $\text{C}_6\text{H}_5(\text{C}_2\text{H}_5)\text{CHO}$  [1:4]. *Cuminol*. *Isopropylbenzoic aldehyde*. Mol. w. 148, (237.5° cor.) (Schiff); (222° cor.) (Lippmann a. Strecker, Sitz. W. [2] 78, 570). S.G. 0.9833;  $n_D^{20}$  1.4972. V.D. 5.24 (calc. 5.13). Occurs, together with cymene, in oil of cumin (from *Cuminum Cyminum*), and in the volatile oil from the seeds of the water-hemlock (*Cicuta virosa*). It is separated from these oils by  $\text{KHSO}_4$  (Gerhardt a. Cahours, A. Ch. [3] 1, 60; Bertagnini, A. 85, 275; Kraut, A. 98, 366; Trapp, A. 108, 386). Formed by boiling  $\text{C}_6\text{H}_5\text{C}_2\text{H}_5\text{CH}_2\text{Cl}$  with lead nitrate and water (Errera, G. 14, 278). Formed also by treating cymene (1 mol.) with  $\text{CrO}_2\text{Cl}_2$  (3 mols.) in  $\text{CS}_2$ , without cooling, and decomposing the product with water (Etard, C. R. 90, 534). The cuminic aldehyde (220°) so formed is perhaps identical with ordinary cuminoic aldehyde. On oxidation it gives a cuminic acid [129°], whence potash-fusion gives *p*-toluic acid.

**Properties.**—Oil, smelling like oil of cumin. Oxidises in the air, becoming resinous.

**Reactions.**—1. Cold fuming  $\text{HNO}_3$  gives *p*-iso-cuminic acid. Hot  $\text{HNO}_3$  forms nitro-iso-cuminic acid.—2. *Chromic acid mixture* gives *p*-iso-cuminic and finally terephthalic acid.—3.  $\text{Cl}$  and  $\text{Br}$  act by substitution.—4.  $\text{NH}_3$  forms hydrocuminamide a thick liquid (Gerhardt a. Cahours; Borodin, B. 6, 1253). According to Uebel (A. 245, 303) it is a stellate mass [65°] which may be reduced by sodium amalgam to cuminyamine and di-cuminyamine, and is converted by dilute acids into  $\text{NH}_3$  and cuminic aldehyde. Sieveking (A. 106, 357) could not obtain it. Aqueous  $\text{NH}_3$  at 130° forms an isomeric base  $\text{C}_9\text{H}_{10}\text{N}_2$  [205°] which forms a sparingly soluble sulphate [192°].—5. *Ammonium sulphide* forms  $(\text{C}_9\text{H}_9\text{S})_2$ .—6. Boiling aqueous and alcoholic potash form cuminyl alcohol and *p*-iso-cuminic acid.—7. *Potash-fusion* gives *p*-iso-cuminic acid and cymene.—8. Heating with potash forms  $\text{C}_{10}\text{H}_7\text{OK}$  (?) (Chiozza, A. 87, 302; cf. Church, P. M. [4] 26, 522).—9. In ethereal solution it is partly converted by treatment with sodium amalgam into the sodium derivative of hydrocuminol  $\text{C}_9\text{H}_9\text{Pr} \cdot \text{CH}(\text{OH}) \cdot \text{CH}(\text{OH}) \cdot \text{C}_6\text{H}_4\text{Pr}$  [135°] (M. Wallach, A. 226, 78; cf. Claus, A. 137, 104).—10. *Acetamide* at 175° gives  $\text{C}_9\text{H}_7(\text{C}_2\text{H}_5)\text{CH}(\text{NHAc})_2$  [212°] (Raab, B. 8, 1160).—11. *Benzamide* gives in the same way  $\text{C}_9\text{H}_7(\text{C}_2\text{H}_5)\text{CH}(\text{NH}_2)_2$  [224°] which crystallises from alcohol in needles, insol. water (R.).—12. *Ethylene-diamine* at 120° gives  $(\text{C}_9\text{H}_7\text{C}_2\text{H}_5\text{CH}_2\text{N})_2$  [64°] (Mason, B. 20, 207).—13. Hydrogen cyanide and  $\text{HCl}$  give  $\text{C}_9\text{H}_7(\text{C}_2\text{H}_5)\text{CH}(\text{OH})\text{CO}_2\text{H}$ .—14. Distillation over  $\text{ZnCl}_2$  gives cymene (Lougheine, Z. 1887, 351).—15. With butyric aldehyde and butyric anhydride it gives  $\text{C}_9\text{H}_7\text{C}_2\text{H}_5\text{CH}(\text{OEt})\text{CO}_2\text{H}$  (Perkin).

**Combination.**— $\text{C}_9\text{H}_9(\text{OH})(\text{SO}_3\text{Na})$  aq; needles, sol. water, insol. cold alcohol, ether, and aqueous  $\text{NaHSO}_4$ .

*Di-methyl-amido-anilide*

$\text{C}_6\text{H}_4(\text{C}_2\text{H}_5)\text{CH}_2\text{N}(\text{C}_2\text{H}_5)_2$  [99°]; small glistening crystals (from alcohol) (Nuth, B. 18, 578).

*Oxim*  $\text{C}_9\text{H}_{12}\text{NOH}$ . [52°]. Formed by the action of hydroxylamine on cuminic aldehyde (Westenberger, B. 16, 2994). Sl. sol. water.

**Derivatives of cuminic orthoaldehyde.**

*Diacetyl derivative*  $\text{C}_9\text{H}_7(\text{C}_2\text{H}_5)\text{CH}(\text{OAc})_2$ . Obtained by the action of silver acetate on  $\text{C}_9\text{H}_7(\text{C}_2\text{H}_5)\text{CHCl}_2$  (from cuminol and  $\text{PCl}_3$ ). Crystals (Sieveking, A. 106, 258).

*Di-benzoyl derivative*

$\text{C}_9\text{H}_7(\text{C}_2\text{H}_5)\text{CH}(\text{OBz})_2$ . [88°]. Needles (Tütt-scheff, A. 109, 368).

*Di-thymyl derivative*

$\text{C}_9\text{H}_7(\text{C}_2\text{H}_5)\text{CH}(\text{OC}_6\text{H}_4)_2$ . [157°]. From  $\text{C}_9\text{H}_7(\text{C}_2\text{H}_5)\text{CHCl}_2$ , thymol, and  $\text{KOH}$  (Engelhardt a. Latschinoff, Z. 1869, 43). Tables.

*Cuminol*  $\text{C}_9\text{H}_{10}\text{O}$  i.e.

$\text{C}_6\text{H}_5(\text{C}_2\text{H}_5)\text{C}(\text{OH})\text{H} \cdot \text{CO} \cdot \text{C}_6\text{H}_5(\text{C}_2\text{H}_5)$ . [101°]. Prepared by boiling cuminic aldehyde with alcoholic  $\text{KCN}$ ; the yield is about 45 p.c. (Böslér, B. 14, 323). Slender white needles; sol. alcohol, ether, and benzene, sl. sol. water and ligroin. It reduces Fehling's solution in the cold. Alcoholic  $\text{KOH}$  gives a violet colouration.

*Acetyl derivative*  $\text{C}_9\text{H}_{10}\text{O}(\text{OAc})$ . [75°]; tables or prisms (Widmann, B. 14, 609).

**Hydrocuminol**

$\text{C}_9\text{H}_7\text{C}_2\text{H}_5\text{CH}(\text{OH})\text{CH}(\text{OH})\text{C}_6\text{H}_4\text{C}_2\text{H}_5$ . [135°].

**Formation.**—1. From cuminol and sodium amalgam.—2. From cuminic aldehyde by treating its ethereal solution with sodium amalgam or with alcoholic  $\text{HCl}$  and zinc (Claus, A. 137, 104; Raab, B. 10, 54).—3. Its di-acetyl derivative is formed by heating cuminic aldehyde with  $\text{NaOAc}$  and  $\text{Ac}_2\text{O}$  at 160° (Widmann, B. 19, 256).

**Properties.**—Small needles (from dilute alcohol). Insol. water. Oxidised by conc.  $\text{HNO}_3$  to cuminol. Pentachloride of phosphorus gives  $\text{C}_9\text{H}_7\text{C}_2\text{H}_5\text{CHCl} \cdot \text{CHCl} \cdot \text{C}_6\text{H}_4\text{C}_2\text{H}_5$  [185°].

*Di-acetyl derivative*  $\text{C}_9\text{H}_7\text{Ac}_2\text{O}_2$ . [144°].

**Deoxy-cuminol**

$\text{C}_9\text{H}_7\text{C}_2\text{H}_5\text{CH}_2\text{CO} \cdot \text{C}_6\text{H}_4\text{C}_2\text{H}_5$ . [58°]. From cuminic aldehyde by treatment with zinc and alcoholic  $\text{HCl}$  (B.). Slender laminae (from dilute alcohol); v. sl. sol. water.

*Cuminil*  $\text{C}_{10}\text{H}_{12}\text{O}$  i.e.

$\text{C}_6\text{H}_4(\text{C}_2\text{H}_5)\text{CO} \cdot \text{CO} \cdot \text{C}_6\text{H}_4(\text{C}_2\text{H}_5)$ . [84°]. Yellow prisms. Sol. alcohol, ether, and benzene, v. sl. sol. water. Distils undecomposed. Prepared by oxidation of cuminol with chlorine. On fusion with caustic potash it gives rise to cumilic acid  $(\text{C}_6\text{H}_4\text{C}_2\text{H}_5)\text{C}(\text{OH})\text{CO}_2\text{H}$  [120°] (Böslér, B. 14, 325).

**Isocuminic aldehyde**  $\text{C}_9\text{H}_{10}\text{O}$ . [80°]. (220°). Formed together with the liquid aldehyde by the action of water upon the compound  $\text{C}_9\text{H}_7\text{C}_2\text{H}_5\text{CH}(\text{OAc})_2$ , obtained from cymene derived from turpentine (Etard, A. Ch. [5] 22, 259). Solid resembling camphor. Oxidised by the air to a cuminic acid [51°].

**CUMINOL v. CUMINIC ALDEHYDE.**

**CUMINURIC ACID**  $\text{C}_9\text{H}_8\text{NO}_2$  i.e.

$[4:1]\text{C}_6\text{H}_4(\text{C}_2\text{H}_5)\text{CO} \cdot \text{NH} \cdot \text{CH}_2 \cdot \text{CO}_2\text{H}$ . [168°]. Occurs in the urine of animals who have been given doses of cymene (Jacobsen, B. 12, 1512). Prepared by the action of cumyl chloride on glycol-silver (Cahours, A. Ch. [3] 58, 356). Glistening scales or large plates. Insol. cold water,  $\text{H}_2\text{O}$ .

sol.-hot water and alcohol. On heating with HCl to 120° it decomposes into glyocol and cuminic acid [117°].

**Salts.**—BaA', aq.: leaflets or flat needles, S. 45 at 6°. —CaA', 3aq.: fine needles, sl. sol. cold water. —KA' and NaA': very soluble fine needles.

#### DI-CUMINYL $C_{10}H_{12}$ i.e.

$C_6H_5.C_6H_4.CH_2.CH_2.C_6H_4.C_6H_5$ , (above 360°). From cuminyl chloride and sodium (Cannizzaro a. Rossi, A. 121, 251). Plates.

#### CUMINYL ALCOHOL $C_{10}H_{12}O$ i.e.

$C_6H_5.Pr.CH_2OH$  [4:1]. Mol. w. 150. (247° cor.). S.G. 1.8978. Formed, together with cuminic acid, by boiling cuminic aldehyde with alcoholic potash (Kraut, A. 92, 66; 192, 224; Fileti, G. 14, 498). Liquid, miscible with alcohol and ether. Boiling with zinc-dust converts it into *n*-cymene, the Pr changing to Pr. Boiling alcoholic KOH forms cuminic acid and cymene. Boiling with small quantities of dehydrating agents converts it into di-cuminyl oxide.

#### CUMINYL-AMIDO-PHENOL

$HO.C_6H_4.NH.CH_2.C_6H_4.Pr$ . *Oxy-phenyl-cuminyl-amine*. [108°]. Formed by reducing with sodium amalgam the product obtained by the action of cuminol on amidophenol (Uebel, A. 245, 297). Greyish white plates. V. e. sol. alcohol, ether.

**Salts.**— $C_{10}H_{11}(NH)(ONa)$ . V. sol. water, giving a red solution. —BHCl. White plates. V. sol. alcohol, hot water, m. sol. cold water.

**Nitrosamine**  $C_{10}H_{11}OH.N.O$ . Yellowish brown crystalline substance. V. sol. alcohol, ether.

#### CUMINYL-AMINE $C_{10}H_{13}N$ i.e.

$C_6H_5(C_6H_4)_2CH_2.NH_2$  [1:4]. *Iso-phenyl-cumene. Isopropyl-benzyl-amine*. (226° at 724 mm.). Prepared by reduction of the oxim of cuminic aldehyde,  $C_6H_5(C_6H_4)_2CH:NOH$  (5 pts.), with sodium amalgam (150 pts.) and acetic acid (12 pts.) in alcoholic solution at 40°–50°; the yield is good (Goldschmidt a. Gessner, B. 20, 2113). Formed also, together with di- and tri-cuminyl-amine, by heating cuminyl chloride with alcoholic  $NH_3$  at 100° (Rossi, C. R. 51, 570; A. Suppl. 1, 141). Also from thio-cuminate amide  $C_6H_5(C_6H_4)_2CS.NH_2$ , zinc and alcoholic HCl (Czumpelik, B. 2, 185). Colourless liquid, of basic smell. Nearly insol. water. Absorbs  $CO_2$  from the air, and solidifies to a crystalline carbamate.

**Salts.**—BHCl: glistening colourless plates, v. sol. water and alcohol. — $B_2H_2Cl_2.PtCl_2$ : nearly insoluble yellow pp.

**Acetyl derivative**  $C_{10}H_{13}(NHAc)$ : [65°]; pearly plates; v. sol. alcohol, ether, and benzene, sl. sol. hot water and hot ligroin.

**Di-cuminyl-amine**  $(C_6H_5.C_6H_4)_2NH$ . [168°]. (c. 290° at 100 mm.). Formed as above (B). Formed also by the action of sodium amalgam on the product of the action of dry  $NH_3$  on cuminic aldehyde (Uebel, A. 245, 309). Crystals, insol. water, v. sol. alcohol and ether. Forms a crystalline nitrosamine.

**Salts.**—BHCl: plates (from alcohol); v. al. sol. cold, m. sol. hot, water, v. e. sol. alcohol. — $B_2H_2Cl_2.PtCl_2$ : yellow needles.

**Tri-cuminyl-amine**  $(C_6H_5.C_6H_4)_3N$ . [82°]. Formed as above (B). Its hydrochloride forms needles, insol. water.

#### CUMINYL-CARBAMATE

$NH_2.CO_2.CH_2.C_6H_4.C_6H_5$ . [89°]. Formed, together with  $\omega$ -chloro-cymene, by passing cyanogen chloride into cuminyl alcohol (Spica, G. 5, 394). Prisms, not volatile with steam. Sl. sol. cold, v. sol. hot, water.

#### CUMINYL CHLORIDE v. $\omega$ -CHLORO-CYMESE.

**CUMINYL-ETHYL OXIDE**  $C_8H_9.Pr.O.Et$ . (227°). From  $\omega$ -chloro-cymene and alcoholic KOH (Errera, G. 14, 282).

#### CUMINYLIDENE-ACETONE

$CH_3.CO.CH:CH.C_6H_4.Pr$ . (181° at 23 mm.). From acetone (20 pts.), cuminic aldehyde (20 pts.), water (300 pts.), alcohol (170 pts.), and NaOH (2 pts.) in the cold (Claisen a. Ponder, A. 223, 147). Thick yellowish oil.

**Di-cuminylidene-acetone**  $(C_6H_5.Pr.CH:CH)_2.CO$ . [107°]. From cuminic aldehyde (20 pts.), acetone (4 pts.), water (300 pts.), alcohol (250 pts.), and NaOH (2 pts.), in the cold (C. a. P.). Lops light-yellow prisms (from alcohol).

#### CUMINYLIDENE-AMIDO-PHENOL

$HO.C_6H_4.N:CH.C_6H_4.Pr$ . [183°]. Formed by the action of amidophenol on an alcoholic solution of cuminol (Uebel, A. 245, 296). Green prismatic needles (from alcohol). Is converted by sodium amalgam into cuminyl amido-phenol.

#### CUMINYLIDENE CHLORIDE v. $\omega\omega$ -DI-CHLORO-CYMESE.

**DI-CUMINYLIDENE-ETHYLENE-DIAMINE**  $C_{22}H_{24}N_2$  i.e.  $C_6H_5(N:CH.C_6H_4.Pr)_2$ . *Di-isopropyl-benzylidene-ethylene diamine*. [64°]. Formed by heating ethylene diamine (1 mol.), with cuminic aldehyde (2 mols.) to 120°. Long white needles. Easily soluble in alcohol, benzene, chloroform, and petroleum-ether. Decomposed into its constituents by acids or by heating with water (Mason, B. 20, 270).

**CUMINYLIDENE-DI-METHYL-*p*-PHENYLENE DIAMINE**  $Pr.C_6H_4.CH:NC_6H_4.NMe_2$ . [100°]. Formed by the action of  $Pr.C_6H_4.CHO$  on dimethylaniline (Uebel, A. 245, 299). Lemon-yellow needles. V. sol. alcohol and ether, insol. water. Is decomposed by acids or alkalis into its components.

**CUMINYL-DI-METHYL-*p*-PHENYLENE DIAMINE**  $Pr.C_6H_4.CH_2.NH.C_6H_4.NMe_2$ . [39°]. Formed by reducing cuminylidene-di-methyl-*p*-phenylene-diamine with sodium amalgam in an alcoholic solution (Uebel, A. 245, 300). Colourless prismatic plates. V. e. sol. alcohol and ether. Gives a nitroso-derivative [87°], crystallising in yellow needles. The hydrochloride is v. sol. water, v. e. sol. alcohol, and sl. sol. ether.

#### DI-CUMINYL OXIDE $C_{20}H_{20}O$ i.e.

$(C_6H_5.Pr.CH_2)_2O$ . (350°).

**Formation.**—1. From  $C_6H_5.Pr.CH_2ONa$  and  $C_6H_5.Pr.CH_2Cl$  (Fileti, G. 14, 496).—2. By distilling cuminyl alcohol with dilute  $H_2SO_4$ .—3. One of the products of the action of alcoholic potash on cuminic aldehyde.

**Properties.**—Oil. Boils at 350° with partial decomposition into cuminic aldehyde and cymene.

#### CUMINYL-PHENOL $C_{16}H_{16}O$ i.e.

$C_6H_5.C_6H_4.CH_2.C_6H_4.OH$ . (300°) at 60 mm. Formed by treating a mixture of phenol and cuminyl alcohol with  $HOAc$  and  $H_2SO_4$  (Paternò a. Fileti, G. 5, 383).

#### CUMINYL THIOCARBIMIDE

$C_6H_5.Pr.CH.NCS$ . (245°–270°). From di-cuminyl-thio-urea and  $P_2O_5$  (Raab, B. 10, 52).

## CUMINYL-THIO-UREA

$C_6H_5(C_6H_5).CH.NHCS.NH$  [1.4]. *Propyl-benzyl-thio-urea*. [c. 110°]. Formed by mixing solutions of ammonium sulphocyanide and cumyl-amine hydrochloride, and evaporating to dryness. Colourless plates (Goldschmidt a. Gessner, B. 20, 2416).

## Di-cumyl-thio-urea

$\{C_6H_5(C_6H_5).CH_2.NH\}_2CS$  [1.4]. *Di-p-propyl-di-benzyl-thio-urea*. [128°]. Formed by the action of alcoholic sulphide of carbon upon cumylamine  $C_6H_5(C_6H_5).CH_2.NH_2$ . Glistening needles (Raab, B. 10, 53; Goldschmidt a. Gessner, B. 20, 2415).

CUMINYL-UREA  $C_6H_5CH_2ON$ , i.e.

$C_6H_5(C_6H_5).CH_2.NH.CO.NH_2$  [1.4]. *Propyl-benzyl-urea*. [135°]. Formed by warming a solution of cumylamine hydrochloride with potassium cyanate. Slender white needles (from hot water) (Raab, B. 8, 1151; Goldschmidt a. Gessner, B. 20, 2414).

*Di-cumyl-urea*  $(C_6H_5.C_6H_5.CH_2.NH)_2CO$ . [122°]. From cumyl cyanate and cumyl amine (Raab, B. 10, 52). Small needles.

CUMONITRILE v. *Nitrile of CUMINIC ACID*.

## CUMOPHENOL v. CUMENOL.

## CUMOQUINOLINE v. (iso)-PROPYL-QUINOLINE.

$\psi$ -CUMOQUINONE  $C_8HMe_2O_2$  [2:3:5:4:1]. [11°]. Formed by oxidising isoduridine  $C_8HMe_2(NH_2)$  [2:3:5:4:1]. Needles (from water). Liquid above 11°. Reduced by  $SO_2$  to hydro-cumoquinone  $C_8HMe_2(OH)_2$  [169°] (Nolting a. Baumann, B. 18, 1152).

 $\psi$ -CUMOQUINONE CARBOXYLIC ACID

$C_8Me_2O_2.CO_2H$  [1:3:4:2:5:6]. [128°]. Formed by oxidising an aqueous solution of the chloride of di-amido-tri-methyl-benzoic acid with  $Fe_2Cl_6$  (Nef, A. 237, 11). Golden yellow needles. V. sol. alcohol, ether, chloroform, m. sol. petroleum ether.

*Reactions*.—Liberates  $CO_2$  from carbonates; sol. alkalis and ammonia with yellow colour. Hydroxylamine yields an unstable quinone oxim.  $HNO_3$  (1.4) yields nitro-tri-methyl-quinone. Reduced by zinc-dust and aqueous NaOH to di-oxy-tri-methyl-benzoic acid. The Ag, Pb, Ba, and Cu salts are all yellow.

*Ethyl ether*  $C_8O_2Me.CO_2Et$ . [51°]. Yellow needles. V. sol. alcohol and ether, m. sol. ligroin.

## CUMOSTRIL v. (Py. 3)-OXY-(B. 3)-ISOPROPYL-QUINOLINE.

**CUMYL**. This name is sometimes given to the radicles cumyl  $C_6H_5.CH_2$  and cuminoyl  $C_6H_5.CO$ , but it is used in this dictionary to denote the radicle  $C_6H_5$ ; cumyl being propyl-phenyl, while  $\psi$ -cumyl is  $\alpha$ -tri-methyl-phenyl.

CUMYL ACRYLIC ACID  $C_6H_5O_2$ , i.e.

$C_6H_5(C_6H_5).CH:CH.CO_2H$  [4:1]. *Isopropyl-cinnamic acid*. [158°]. From cuminic aldehyde, NaOAc, and  $Ac_2O$  (Perkin, C. J. 31, 388; Widmann, B. 19, 255). Needles (from alcohol). V. sol. alcohol and HOAc, al. sol. boiling water. Split up by heat into  $CO_2$  and isopropyl-styrene. Aqueous  $CrO_3$  gives cuminic aldehyde. Sodium amalgam gives  $\beta$ - $\alpha$ -cumyl-propionic acid.

*Salts*.— $NH_4A'$ : asbestos-like crystals, m. sol. water.— $CaA_2$ : needles, sl. sol. water; absorbs oxygen at 100°.— $SrA_2$  2aq.— $AgA'$ : bulky pp.

*Chloride*  $C_6H_5.Pr.CH:CH.COCl$ . [c. 25°].

*Amide*  $C_6H_5.Pr.CH:CH.COONH_2$ . [186°].

## Derivatives v. AMIDO-, NITRO-, and OXY-CUMYL ACRYLIC ACID.

*Di-bromide*  $C_6H_5(C_6H_5).CHBr.CHBr.CO_2H$ . [190°]. Small white balls. Sparingly sol. in hot benzene (Widmann, B. 19, 258).

 $\psi$ -CUMYL-AMIDO-CROTONIC ACID

$Me_2C_6H_5NH.C(Me):CHCO_2Et$ . Formed by the action of acetoacetic ether on  $C_6H_5Me_2(NH_2)$  [1:2:4:5] (Conrad a. Limpach, B. 21, 528). Viscous mass. Yields on distillation di-cumyl-urea and a quinoline derivative.

*Methyl ether*  $MeA'$ . [60°]. Formed by the action of methyl acetoacetate on  $\psi$ -cumidine (Conrad a. Limpach, B. 21, 528). White crystals (from alcohol). Yields a quinoline derivative on distillation.

**CUMYL-ANGELIC ACID**  $C_6H_5O_2$ , i.e.  $C_6H_5(C_6H_5).CH:CH.CO_2H$ . [123°]. From cuminic aldehyde, butyric anhydride, and sodium butyrate (Perkin, C. J. 31, 403). Needles (from alcohol). Forms a crystalline dibromide.

## CUMYL BROMIDE v. BROMO-CUMENE.

## CUMYL CHLORIDE v. CHLORO-CUMENE.

**CUMYL-CROTONIC ACID**  $C_6H_5O_2$ , i.e.  $C_6H_5(C_6H_5).CH:CH.CO_2H$ . [91°]. From cuminic aldehyde, propionic anhydride, and NaOAc (Perkin, C. J. 31, 403; 35, 137). Nodules (from alcohol) or prisms (from light petroleum).— $AgA'$ : bulky pp.

*Di-bromide*  $C_6H_5(C_6H_5).CHBr.CMe.Br.CO_2H$ . [140°–150°]. Prisms. Converted by KOH into allyl-isopropyl-benzene.

 $\psi$ -CUMYLENE- $m$ -DIAMINE  $C_8HMe_2(NH_2)_2$ 

[1:3 1:2:6]. [84°]. Formed by reduction of nitro- $\psi$ -cumidine (from tri-nitro- $\psi$ -cumene) or of the corresponding nitro- $\psi$ -cumidine sulphonic acid. Long thick needles.  $Fe_2Cl_6$  gives a dark red colouration. Gives the Bismarck-brown and chrysoidine reactions. The hydrochloride forms white plates (Mayer, B. 20, 970).

## Isomerides v. DI-AMIDO-CUMENE.

## CUMYLENE BROMIDE v. DI-BROMO-CUMENE.

DI- $\psi$ -CUMYL-ETHYLENE-DI-KETONE

[5:4:2:1].  $C_6H_5Me_2.CO.CH_2.CH_2.CO.C_6H_5Me_2$  [1:2:4:5]. [120°]. Formed by the action of succinyl-chloride upon  $\psi$ -cumene (over 2 mols.) in presence of  $AlCl_3$ . On oxidation it gives tri-methyl-benzoic acid [150°] (Claus, B. 20, 1378).

$\psi$ -CUMYL-ETHYL-KETONE- $\alpha$ -CARBOXYLIC ACID  $C_6H_5Me_2.CO.CH_2.CH_2.CO_2H$  [5:4:2:1]. [105° uncor.]. Its chloride is formed by the action of succinyl chloride (1 mol.) upon  $\psi$ -cumene (1 mol.) in presence of  $AlCl_3$ . Small colourless crystals (Claus, B. 20, 1378).

$\psi$ -CUMYL-HYDRAZINE  $C_6H_5(CH_2)_3.NH.NH_2$  [1:3:4:6]. [120°]. Formed by reduction of the sulphite of diazo- $\psi$ -pseudo-cumene with zinc-dust and acetic acid, and heating the sulphite which is formed with dilute  $HCl$  (Haller, B. 18, 91). Colourless needles, v. sol. alcohol and ether, nearly insol. water. By boiling with aqueous  $CuSO_4$  it is converted into pseudo-cumene.

**CUMYLIDENE-ETHYLENE-ANILINE v. DI-PHENYL- $\psi$ -CUMYL-METAPYRAZOL-TETRAHYDRIDE.**

**CUMYLIZIN-ACETO-ACETIC ETHER v. ACETO-ACETIC-ETHER-CUMYL-HYDRAZIDE.**

**DI-CUMYL DI-KETONE is Cumilin v. CUMINIC ALDEHYDE.**

**CUMYL PROPYL-BENZYL KETONE is Do-*oxy-cuminoin* v. CUMINIC ALDEHYDE.**

**ψ. CUMYL MERSAPTAN**  $C_8H_7S$  *i.e.*  $C_8H_7Me_3(SH)$  [1:2:4:5]. [87°]. (235°). Formed by reduction of ψ-cumene sulphonic chloride (Beilstein a. Kögler, A. 137, 322). Laminae (from alcohol).— $(C_8H_7Me_3S)_2Hg$ : needles (from alcohol) (Radloff, B. 11, 32).

**CUMYL METHYL KETONE**  $C_8H_7Pr.CO.CH_3$ . (253° i.v.). S.G. 12.976. From cumene,  $AcCl$ , and  $Al_2Cl_3$  (Widmann, B. 21, 2225).

*Oxim*  $C_8H_7Pr.C(NOH).CH_3$ . [71°]. Trimetric tables (from ligroin).

**p-CUMYL-PROPIONIC ACID**  $C_{11}H_{10}O_2$  *i.e.*  $C_8H_7(C_2H_5).CH_2.CH_2.CO_2H$ . [76°]. From cumyl-acrylic acid and sodium-amalgam or  $HI$  (Perkin, C. J. 31, 388; Widmann, B. 19, 2773). Laminae (from ligroin).— $AgA'$ .

**ψ-CUMYL DISULPHIDE**  $(C_8H_7Me_3)_2S_2$ . [115°]. From ψ-cumyl mercaptan and ψ-cumene sulphonic acid in alcohol (Radloff, B. 11, 32).

**DI-ψ-CUMYL-THIO-UREA**  $SC(NH.C_8H_7Me_3)_2$ . [146°]. Formed by heating ψ-cumidine (224°) with  $CS_2$ . Prismatic crystals. Sol. hot alcohol, sl. sol. ether, insol. water (Engel, B. 18, 2233).

**ψ-CUMYL-UREA**  $C_8H_7Me_3.NH.CO.NH_2$ . Formed by mixing aqueous solution of (σ)-cumidine hydrochloride and potassium cyanate. White needles. Sol. hot alcohol, sl. sol. ether, insol. water. Decomposes at c. 227° without melting, evolving  $NH_3$  and giving di-(σ)-cumyl-urea (Engel, B. 18, 2232).

**o-Cumyl-urea** [2:1]  $C_8H_7Pr.NH.CO.NH_2$ . [134°]. Small needles (Constam a. Goldschmidt, B. 21, 1157).

**p-Cumyl-urea** [4:1]  $C_8H_7Pr.NH.CO.NH_2$ . [152°]. Slender needles (C. a. G.).

**Di-ψ-cumyl-urea**  $OC(NH.C_8H_7Me_3)_2$ . [above 290°]. White silky needles. Sublimable. Sl. sol. alcohol. Formed by heating the monocumyl-urea,  $NH_3$  being evolved (Engel, B. 18, 2233).

**Di-ψ-cumyl-urea**  $Me_3C.H_7.NH.CO.NH.C_8H_7Me_3$ . [above 300°]. Is a product of the distillation of the ethyl or methyl ether of ψ-cumyl-amido-crotonic acid  $C_8H_7Me_3.NH.CMe:CH.CO_2H$  (Conrad a. Limpach, B. 21, 528). White needles, insol. ordinary solvents.

**CUPREINE v. CINCHONA BASES.**

**CUPRONINE v. NARCOTINE.**

**CURARINE**  $C_{16}H_{23}N$  (?) Occurs as sulphate in curara or urari, a resinous arrow-poison used by the South American Indians, and said to be obtained by boiling a climbing plant of the genus *Strychnos* with water. Deliquescent prisms; v. sol. water and alcohol, m. sol. chloroform, insol. ether. It is coloured red by conc.  $H_2SO_4$ .  $HNO_3$  gives a purple-red colour.  $K_2SO_4$  and  $H_2SO_4$  give a violet colour like that from strychnine.— $B'H_3PtCl_6$ : yellowish white pp.—Pierate  $B'C_6H_5(NO_2)_3.OH$ : yellow pp. (Ronlin a. Boussingault, A. Ch. [2] 39, 24; A. von Humboldt, A. Ch. [2] 39, 30; Pelletier a. Pétoz, A. Ch. [2] 40, 213; Pelonze a. Cl. Bernard, C. R. 31, 553; 40, 1327; Reynoso, C. R. 39, 697; Pelikan, C. R. 44, 507; Milleroux, C. R. 47, 973; Preyer, Bl. [2] 4, 238; Dragendorff, Z. [2] 3, 28; Bert, C. C. 1865, 958; Schnetzler, N. Arch. ph. nat. 24, 318; Flückiger, N. Repert. Pharm. 22, 65; Koch, C. C. 1871, 219; Salomon,

Fr. 10, 454; Boehm, C. C. 1887, 520; Sachs, A. 191, 254; Villiers, J. Ph. [5] 11, 653).

**CURECUMIN**  $C_{14}H_{11}O_6$ . [178°]. The colouring matter of turmeric root, from which it may be obtained by extracting with ether after removing an oil by ligroin (Vogel, Schw. J. 18, 212; Pelletier a. Vogel, J. Ph. 1815, 259; Vogel, jun. A. 44, 297; Daube, B. 3, 609; Schützenberger, Bl. [2] 5, 194; Jackson a. Menke, Am. 4, 79; 6, 77; P. Ann. A. 17, 110). Stout needles (from alcohol); nearly insol. water, benzene,  $CS_2$ , and ligroin; sol.  $HOAc$ , alcohol, and ether. Its ethereal solution exhibits green fluorescence. Its alkaline solutions are brown, but it is reppd. unaltered by acids. Salts of Ba, Ca, and Pb give brown pps. in the alkaline solution. Paper stained with curcumin and moistened with boric acid becomes, according to Daube, orange after drying; turmeric paper becomes crimson under these conditions; in either case the colour is turned bluish-black by alkalis. Treatment with boric acid and conc.  $H_2SO_4$  gives 'rosocyanin,' of which the solutions are magenta and the metallic salts blue. Chromic acid mixture oxidises curcumin to terephthalic acid (Gajevsky, B. 6, 196). According to Kachler (B. 3, 713) distillation over zinc-dust yields anthracene.

Metallic derivatives  $C_{14}H_9KO_2$ : very dark crimson amorphous body, sol. water and alcohol.— $C_{14}H_9K_2O_4$ : orange-red needles, sol. water, insol. ether. Long boiling with  $EtI$  forms a di-ethyl derivative.

**Acetyl derivative**  $C_{14}H_9AcO_2$ . Brown mass, sol. alcohol and  $HOAc$ , sl. sol. ether and benzene, insol.  $CS_2$ .

**Diacetyl derivative**  $C_{14}H_9Ac_2O_4$ . [154°]. Formed by heating curcumin with  $Ac_2O$  and  $NaOAc$ . Yellow trimetric plates. Conc.  $H_2SO_4$  forms a blood-red solution with green reflex.

**p-Bromo-benzyl derivative**  $C_{14}H_9(C_6H_4BrMe)O_2$ . [78°]. From potassium curcumin and p-bromo-benzyl bromide in alcohol. Yellow crystals, sol. alcohol and  $HOAc$ . Oxidised by  $KMnO_4$  to vanillin.

**CUSCAMINE v. CINCHONA BASES.**

**CUSCONIDINE v. CINCHONA BASES.**

**CUSCONINE v. CINCHONA BASES and ARICINE.**

**CUSPARINE**  $C_{10}H_7NO_3$ . [92°]. An alkaloid present in the Angustura bark (from *Cusparia febrifuga*). An ethereal solution of this bark yields with oxalic or sulphuric acids pps. of the corresponding salts as yellow crystalline substances, which yield on decomposition the alkaloid. Long colourless needles, sol. petroleum. Decomposed by potash into an aromatic acid, and another alkaloid (250) (Körner a. Böhringer, G. 13, 363; cf. Saladin, J. chim. méd. 1833, 9, 388; Herzog, Ar. Ph. [2] 93, 146).

**Salts.**—The sulphate, hydrochloride, and oxalate are sparingly soluble, the tartrate is readily soluble in water. The platinochloride is an orange yellow pp.

**CYAMELIDE v. CYANIC ACID.**

**CYAMELURIC ACID v. CYANIC ACID.**

**CYAMIDO- = CYANAMIDO-.**

**CYANAMIDE v. CYANIC ACID.**

**Di-cyan-diamide v. CYANIC ACID.**

**CYANAMIDE-CARBOXYLIC ACID**

\*  $Cy.NH.CO_2H$ . Only some salts of this dibasic

acid are known (G. Meyer, *J. pr.* 126, 419). The acid, when liberated, splits up into  $\text{CO}_2$  and cyanamide.

**Salts.**— $\text{CyNNa.CO}_2\text{Na}$ . Formed by passing carbonic acid into a boiling alcoholic solution of sodium cyanamide:  $2\text{CyNNaH} + \text{CO}_2 = \text{CyNH}_2 + \text{CyNNa.CO}_2\text{Na}$ . Amorphous powder, insoluble in alcohol, soluble in water. May be obtained in groups of microscopic needles by dropping its aqueous solution into alcohol. Converted by fusion into the isomeric sodio cyanate.— $\text{CyNK.CO}_2\text{K}$ . Got by passing  $\text{CO}_2$  into boiling alcoholic potassium cyanamide. Resembles the foregoing sodium salt.— $\{\text{CyN}(\text{CO}_2)\}\text{Ca}, 5\text{aq}$ . In a similar way from calcium cyanamide, by passing  $\text{CO}_2$  into its alcoholic solution. Thin white needles, slightly soluble in water. Its aqueous solution is decomposed by heat into  $\text{CaCO}_3$  and cyanamide.— $\{\text{CyN}(\text{CO}_2)\}\text{Sr}, 2\text{aq}$ . Gritty crystalline powder, resembling the calcium salt.— $\{\text{CyN}(\text{CO}_2)\}\text{Ba}, 1\frac{1}{2}\text{aq}$ . Resembles the strontium salt.

**Reactions.**—A solution of the potassium salt gives:—1. With silver nitrate a pp. of silver cyanamide and evolution of  $\text{CO}_2$ .—2. With basic lead acetate a white pp. of lead carbonate, cyanamide being in solution.

**Ethyl ether  $\text{CN.NH.CO}_2\text{Et}$ .** From cyanamide di-carboxylic ether and alcoholic KOH (Bässler, *J. pr.* [2] 16, 146). Syrup. Readily polymerises.— $\text{B}^2\text{HCl}$ : crystalline powder, v. sol. water; converted by boiling water into allophanic ether.— $\text{CN.NNa.CO}_2\text{Et}$  [241°]: needles; split up by heat into  $\text{NaCyO}$  and  $\text{EtN.CO}$ .— $\text{CN.NK.CO}_2\text{Et}$  [199°]. Converted by  $\text{EtH}$  at 150° into  $\text{CN.NEt.CO}_2\text{Et}$  (213°).— $\text{HO.Ca.NCy.CO}_2\text{Et}$ .— $\text{CN.NAg.CO}_2\text{Et}$ .

**Cyanamide di-carboxylic ether**  
 $\text{CN.N}(\text{CO}_2\text{Et})_2$  [33°]. From sodium cyanamide and  $\text{Cl.CO}_2\text{Et}$  (Bässler, *J. pr.* [2] 16, 134). Prisms. Insol. water. Boiling water decomposes it into  $\text{CO}_2$ , alcohol, and cyanamide carboxylic ether.

#### CYANAMIDO-BENZOIC ACID

$\text{CN.NH.C}_6\text{H}_4\text{.CO}_2\text{H}$  [13]. [above 200°]. Flat pearly needles (containing  $\frac{1}{2}\text{aq}$ ). Sol. hot water, alcohol and ether, nearly insol. cold water and benzene. Formed by the action of cyanogen chloride on an alcoholic solution of *m*-amido-benzoic acid.

**Reactions.**—Heated with baryta-water to 140° it decomposes into *m*-amido-benzoic acid  $\text{CO}_2$  and  $\text{NH}_3$ . It is not altered by boiling with water, and only slowly with  $\text{NaOH}$ . Heated to 140° alone it evolves cyanic acid leaving a white amorphous insoluble substance. Boiled with dilute  $\text{HCl}$  it is converted into *m*-uramido-benzoic acid. With ammonium sulphide it gives *m*-thio-uramido-benzoic acid. On heating the barium-salt polymeric substances are formed. It combines with aniline to form a di-phenyl-guanidine-carboxylic acid.

**Salts.**—The salts of the alkalis, alkaline earths, and of  $\text{Zn}$ ,  $\text{Hg}$ ,  $\text{Ni}$  and  $\text{Co}$  are easily soluble.  $\text{Fe}_2\text{Cl}_3$  gives a yellow amorphous pp.  $\text{AgNO}_3$  gives a white gelatinous pp. and  $\text{CuSO}_4$  gives a brown flocculent pp. (Traube, *B.* 15, 2118).

#### DICYANAMIDO-BENZOYL v. vol. i. p. 155.

#### p-CYANAMIDO-PHENYL-ACETIC ACID

$\text{CN.NH.C}_6\text{H}_4\text{.CH}_2\text{CO}_2\text{H}$  [184°]. Formed by the action of cyanogen chloride on *p*-amido-phenyl-

acetic acid in alcoholic solution (Traube, *B.* 15, 2121). Colourless plates or tables. V. sol. water, alcohol and ether. It is very unstable. Dilute  $\text{HCl}$  converts it into *p*-uramido-phenyl-acetic acid.  $\text{CuSO}_4$  gives a brown pp. soluble in alcohol.

#### CYANANILINE ( $\text{C}_6\text{H}_5\text{NH}_2$ ), $\text{C}_6\text{H}_5\text{N}_2$ .

**Formation.**—By the action of aniline upon oximido-ether:

**Preparation.**—1. Aniline (1 pt.) is dissolved in alcohol (5 pts.) and cyanogen is passed in (Hofmann, *A.* 66, 129; 73, 180).—2. Aniline (10g.) is dissolved in alcohol (30g.) and water (60g.) is then added. On passing cyanogen gas into the solution cyananiline separates; it is purified by solution in dilute  $\text{H}_2\text{SO}_4$  and reppn. by  $\text{NH}_3$  (Sent, *J. pr.* [2] 35, 514).

**Reactions.**—1. Dry nitrous acid gas passed into ether containing cyananiline in suspension forms the nitrate  $\text{B}^2\text{HNO}_3$ . Nitrous acid gas passed into a solution of cyananiline in 65 p.c. acetic acid forms oxanilide, (1, 3, 4)-di-nitro-phenol, and phenyl-carbamine. Nitrous acid gas passed into a solution of cyananiline in glacial  $\text{HOAc}$  forms the same products, and also di-*p*-nitro-oxanilide.—2. Sodium amalgam forms  $\text{NH}_3$ , aniline, and formic acid.—3. Bromine in chloroform solution at 0° forms unstable amorphous  $\text{C}_6\text{H}_4\text{N}_2\text{Br}_2$ , which is probably ( $\text{C}_6\text{H}_4\text{Br.NH.C}(\text{NH}).\text{C}(\text{NH}).\text{NH.C}_6\text{H}_4\text{Br}$ ), being reduced by  $\text{SO}_2\text{Aq}$  to di-bromo-cyananiline. Bromine in boiling glacial  $\text{HOAc}$  forms di-*p*-bromo-cyananiline. Bromine-water forms tri-bromo-aniline.—4.  $\text{MeI}$  at 120° gives dimethyl-aniline.—5. Phthalic anhydride gives phthal-anil,  $\text{C}_6\text{H}_4(\text{C}_6\text{O}_5)\text{NPh}$  (Sent, *J. pr.* [2] 35, 537).

**Salts.**— $\text{B}^2\text{HNO}_3$ : [192°]; decomposed on melting, with evolution of phenyl-carbamine.— $\text{B}^2\text{H}_2\text{Cl}_2$ .— $\text{B}^2\text{H}_2\text{PtCl}_4$ .— $\text{B}^2\text{H}_2\text{AuCl}_4$ .— $\text{B}^2\text{H}_2\text{Br}_2$ .

Di-*p*-bromo-cyananiline  $\text{C}_6\text{H}_4\text{N}_2\text{Br}_2$  i.e.  $\text{C}_6\text{H}_4\text{Br.NH.C}(\text{NH}).\text{C}(\text{NH}).\text{NH.C}_6\text{H}_4\text{Br}$ . [245°]. From cyananiline and bromine; or by the union of *p*-bromo-aniline and cyanogen (Sent, *J. pr.* [2] 35, 530). White plates (from alcohol).

**CYANATES (METALLIC).** Cyanic acid has the composition  $\text{HCNO}$ ; several isomerides of this composition may exist (v. CYANIC ACID). The metallic cyanates are probably salts of the acid  $\text{NC.OH}$ . A polymeride of cyanic acid,  $\text{H}_2\text{C}_2\text{N}_2\text{O}_2$ , exists; this acid is known as *cyanuric acid*. Isomerides of this composition are possible; *cyanuric acid* very probably has the constitution  $(\text{CN})_3(\text{OH})$ , (v. p. 310), and the metallic cyanurates are salts of this acid (v. CYANURATES). Another polymeride of cyanic acid is also known, *Cyameline* (v. CYANIC ACID).

**CYANATES.** Metallic cyanates are most probably all salts of the acid  $\text{CN.OH}$ . They are produced in the following among other reactions: (1) by passing cyanogen into solution of an alkali or alkaline earth; (2) by heating alkaline carbonates to low redness in cyanogen, or with mercuric cyanide; (3) by fusing alkaline cyanides or ferrocyanides with an easily reduced oxide, such as  $\text{PbO}$ , or with a nitrate; (4) by electrolysis of  $\text{KCN}$  aq; some cyanates are obtained from  $\text{KCN}$  aq by double decomposition. Most metallic cyanates are soluble in water, the

cyanates of Cu, Pb, Hg, and Ag are only slightly soluble. Alkali cyanates are not decomposed by heating to dull redness in dry air; in moist air they give carbonates of  $\text{NH}_4$  and the alkali. Cyanates of the alkaline earths, and of most heavy metals, are decomposed by heat to  $\text{CO}_2$  and cyanide of the metal (v. Drechsel, *J. pr.* [2] 16, 201). Acids decompose cyanates, forming  $\text{CO}_2$  and  $\text{NH}_3$ , sometimes with a little unchanged cyanic acid; some acids ppt. solid K cyanurate from  $\text{KCNOAq}$ .

**Ammonium cyanate**  $(\text{NH}_4)\text{CNO}$ . Obtained by passing  $\text{NH}_3$  into an ethereal solution of  $\text{HCNO}$ , or by bringing together dry  $\text{NH}_3$  and  $\text{HCNO}$  vapour. Very soluble in water. Easily changed into its isomeride urea (Liebig & Wöhler, *P.* 20, 369, 395; *A.* 59, 291).

**Potassium cyanate**  $\text{KCNO}$ . S.G. 2.05. H.F.  $[\text{K}, \text{C}, \text{N}, \text{O}] = 102,300$ ;  $[\text{KCN}, \text{O}] = 72,000$ ;  $[\text{KCNO}, \text{Ag}] = -5,200$  (Berthelot, *C. R.* 91, 82).

**Formation**.—1. By heating KCN in air, or in presence of an easily reduced oxide.—2. By passing cyanogen into  $\text{KOHAq}$ , or over heated  $\text{K}_2\text{CO}_3$  (Wöhler, *G. A.* 73, 157).—3. By electrolyzing  $\text{KCNAq}$  (Kolbe, *A.* 64, 236).—4. By deflagrating  $\text{KNO}_3$  with  $\text{KFe(CN)}_6$ , or  $\text{Hg(CN)}_2$ , or nitrogenous charcoal (W., *G. A.* 73, 157).

**Preparation**.—4 parts dry pulverised  $\text{KFe(CN)}_6$  are mixed with 3 parts dry pulverised  $\text{K}_2\text{Cr}_2\text{O}_7$ ; a little of the mixture is placed in a porcelain or iron dish, which is heated considerably below redness until the mixture becomes like tinder and blackens; the rest of the mixture is then thrown in little by little, each quantity being allowed to blacken before the next is added (complete oxidation of KCN to KCNO is thus ensured). After cooling, the contents of the dish are added to successive quantities of boiling alcohol, as much being added to each quantity of alcohol as suffices to saturate the latter; the alcoholic solution is cooled, and the crystals of KCNO are dried between paper, and then *in vacuo* over  $\text{H}_2\text{SO}_4$ . The yield is about 42 p.c. of the  $\text{KFe(CN)}_6$  used; if carefully conducted the KCNO contains about 1 p.c. impurities (Bell, *C. N.* 32, 99; modification of method of Liebig & Wöhler, *A.* 38, 108; 41, 289; v. also Clemm, *A.* 66, 382).

**Properties**.—Small colourless odourless laminae, resembling  $\text{KClO}_3$ ; fuses below redness to a colourless liquid, soluble in water, fairly soluble in boiling hydrated alcohol; insoluble in absolute alcohol.

**Reactions**.—1. Unchanged by heat; but if water is present the salt is decomposed to  $\text{K}_2\text{CO}_3$  and  $\text{NH}_3$ .—2. Reduced to KCN by heating in hydrogen, or with potassium, iron, or carbon.—3. Melted with sulphur gives  $\text{K}_2\text{S}$ ,  $\text{KSCN}$ , and  $\text{K}_2\text{SO}_4$ .—4. Sulphuric acid forms  $\text{K}_2\text{S}$  and  $\text{KSCN}$  with some  $\text{NH}_3$  sulphide.—5. Heated in hydrochloric acid gas,  $\text{KCl}$  and  $\text{NH}_4\text{Cl}$  are formed. 6. Sodium amalgam reacts with a neutral solution to produce formamide ( $\text{HCO.NH}_2$ ).

The other cyanates have not been much studied. Insoluble cyanates, e.g. of Pb or Ag, may be obtained by proceeding as directed for preparation of KCNO, but exhausting the heated mass with very cold water, removing  $\text{K}_2\text{CrO}_4$  by  $\text{Ba(NO}_3)_2\text{Aq}$ , and ppg. by solution of a nitrate of the metal. The following cyanates have been isolated.

**Barium cyanate**  $\text{Ba(CNO)}_2$  (Wöhler, *A.* 45, 357). By adding alcohol to a mixture of  $\text{KCNOAq}$  and Ba acetate; crystalline.

Calcium cyanate has not been crystallised; obtained by passing  $\text{HCNO}$  vapour into milk of lime.

**Cobalt-potassium cyanate**  $\text{Co(CNO)}_2 \cdot 2\text{KCNO}$  (Blomstrand, *J. pr.* [2] 3, 207). Dark blue quadratic crystals; obtained by adding  $\text{KCNOAq}$  to Co acetate solution.

Copper cyanate, not crystallised; by mixing solution of Cu acetate and Ba cyanate.

**Lead cyanate**  $\text{Pb(CNO)}_2$  (Wöhler, *G. A.* 73, 157; Williams, *J. pr.* 104# 255). Crystalline, nearly insoluble in hot water.

**Silver cyanate**  $\text{AgCNO}$  (W., *G. A.* 73, 157). By adding  $\text{AgNO}_3\text{Aq}$  to  $\text{KCNOAq}$ ; S.G. 4.0; somewhat soluble in boiling water; dissolved and decomposed by dilute  $\text{HNO}_3\text{Aq}$ ; decomposed by heating, to Ag mixed with C and some N. Soluble in  $\text{NH}_4\text{Aq}$ , giving a double compound which loses  $\text{NH}_3$  in the air.

**Sodium cyanate**  $\text{NaCNO}$ . Resembles KCNO; crystalline.

**Thallium cyanate**  $\text{TlCNO}$ ; tablets, sol. water, insol. alcohol (Kuhlmann, *A.* 126, 78).

M. M. P. M.

**CYANBENZINE** v. *Paranitride* of PHENYL ACETIC ACID.

**CYANBUTINE** v. *Paranitride* of VALERIO ACID.

**CYANCONIINE**  $\text{C}_8\text{H}_{11}\text{N}_3$ . (205°). S.G. .93. Cyanethine heated with HCl gives 'oxy-cyanconiine' (v. *infra*), whence  $\text{PCl}_5$  forms 'chloro-cyanconiine,' which is reduced to cyanconiine. This name is given to the base by E. v. Meyer (*J. pr.* [2] 22, 286), although it is not formed in any way from coniine.

**Properties**.—This base dissolves somewhat in water, forming an alkaline liquid, but it separates again if the solution is warmed. It is a colourless liquid of narcotic odour. It boils at 205°. It is volatile with steam. It is poisonous, and its physiological effects resemble those due to coniine. Its aqueous solution gives with silver chloride crystalline needles of a double salt:  $\text{B'HgCl}_2$ ,  $\lambda_{\text{aq}}$ . [ $\text{c}$ . 90°].

**Combinations**.—1. With *ethyl iodide* at 100° forms a compound, whence by  $\text{AgCl}$  and  $\text{PtCl}_4$  sharp yellow prisms of  $(\text{B'EtCl})_2\text{PtCl}_4$  may be got.—2. With *acetyl chloride* it gives unstable needles, probably  $\text{B'AcCl}$ .

**Reactions**.—Reduced by Zn and HCl to a new base  $\text{C}_8\text{H}_{11}\text{N}_2$ , which forms a zinc double salt (E. v. Meyer, *J. pr.* [2] 26, 340).

**Oxy-cyanconiine**  $\text{C}_8\text{H}_{11}\text{N}_3\text{O}$ . [157°]. S. 76 at 25°. S. (alcohol of 90 p.c.) 8 at 18°.

**Preparation**.—1. This base is got by heating (20 g. of) cyanethine\* ( $\eta$ , v.) with conc. HCl (30 c.c.) for 3 hrs. at 190°. The product is evaporated, mixed with ammonia, and the pp. crystallised from water.—2. It may also be got by passing  $\text{N}_2\text{O}_3$  into a solution of cyanethine in glacial acetic acid (v. Meyer, *J. pr.* [2] 26, 342).

**Properties**.—Bunches of glittering needles (from water), long stiated prisms (from alcohol), or dendritic aggregates (by precipitation). May be sublimed. Sol. chloroform, benzene, and ether.

**Reactions**.—1. Heated with *ethyl iodide* it

forms a syrup, whence by successive treatment with  $\text{Ag}_2\text{O}$ ,  $\text{HCl}$ , and  $\text{PtCl}_4$ , trimetric crystals of  $(\text{B'EtCl})_2\text{PtCl}_4$  are formed. Hence it is a tertiary base.—2. With *acetyl chloride* forms a peculiar compound  $\text{B'AcCl}$ , not decomposed by ammonia (M.).—3. Not affected by heating with  $\text{Ac}_2\text{O}$  at  $180^\circ$ .—4. With  $\text{PCl}_5$  at  $140^\circ$  it gives off  $\text{HCl}$ . Product shaken with solution of  $\text{NaOH}$  and extracted with ether, is found to be an oil  $\text{C}_6\text{H}_{13}\text{N}_2\text{Cl}$ . This reaction looks as if the base contains hydroxyl. It is converted by  $\text{NH}_3$  at  $220^\circ$  into cyanethine:  $\text{C}_6\text{H}_{13}\text{N}_2\text{Cl} + 2\text{NH}_3 = \text{NH}_4\text{Cl} + \text{C}_6\text{H}_{13}\text{N}_2\text{NH}_2$ . Alcoholic potash rapidly removes its chlorine forming a new base:  $\text{C}_6\text{H}_{13}\text{N}_2\text{Cl} + \text{KOEt} = \text{KCl} + \text{C}_6\text{H}_{13}\text{N}_2\text{OEt}$ . The new base is an oil smelling of herbs and boiling at  $230^\circ$ . Its platinum salt crystallises in octahedra  $(\text{B'EtCl})_2\text{PtCl}_4$ . Heating with fuming  $\text{HCl}$  at  $210^\circ$  it is converted into the original oxy-cyanethine:  $\text{C}_6\text{H}_{13}\text{N}_2\text{OEt} + \text{HCl} = \text{EtCl} + \text{C}_6\text{H}_{13}\text{N}_2\text{O}$ . These various reactions point to the presence of hydroxyl in oxy-cyanethine and of amidogen in cyanethine. The chlorinated base  $\text{C}_6\text{H}_{13}\text{N}_2\text{Cl}$  may be reduced by  $\text{Zn}$  and  $\text{HCl}$ . The zinc double salt of a new base is thus got:  $\text{ZnCl}_2 \cdot \text{C}_6\text{H}_{13}\text{N}_2 \cdot 2\text{HCl}$ . If this salt be treated with solution of  $\text{NaOH}$  and shaken with ether, the ether leaves, on evaporating, cyanethine  $\text{C}_6\text{H}_{13}\text{N}_2$  in the form of an oil. The base  $\text{C}_6\text{H}_{13}\text{N}_2$ , which is first formed in the reduction of chloro-cyanethine, is readily oxidised by  $\text{Ag}_2\text{O}$  to cyanethine.—5. With  $\text{ClCO}_2\text{Et}$  oxy-cyanethine forms a liquid carboxylic ether, which is decomposed by conc. mineral acids into the oxy-base  $\text{CO}_2$  and alcohol (E. v. Meyer, *J. pr.* [2] 80, 121).

**Salts.**—Sol. water. Solutions acid to litmus. —  $\text{B'EtCl}$  (at  $110^\circ$ ). —  $(\text{B'EtCl})_2\text{PtCl}_4$ . —  $\text{B'EtNO}_3$ . —  $\text{B'EtC}_2\text{O}_4$ . Prisms.

Oxy-cyanethine can occasionally act as an acid, for it forms a silver salt  $\text{C}_6\text{H}_{13}\text{AgN}_2\text{O}$ , sol.  $\text{HNO}_3$  and  $\text{NH}_3$ .

**Methyl derivative**  $\text{C}_6\text{H}_{11}\text{MeN}_2\text{O}$ . [ $77^\circ$ ]. (276°). S. 8 at  $18^\circ$ . Mel (5 pts.) is heated with oxy-cyanethine (2 pts.) at  $150^\circ$ . Crystals of  $\text{C}_6\text{H}_{11}\text{MeN}_2\text{O} \cdot \text{H}_2\text{O}$  are got.  $\text{NaOH}$  sets the base free. It forms white needles. Insol. potash.

**Salts.** —  $(\text{B'EtCl})_2\text{PtCl}_4$ : yellow trimetric prisms. —  $\text{HgCl}_2 \cdot \text{B'Et}$ : needles grouped in stars.

**Ethyl derivative**  $\text{C}_6\text{H}_{11}\text{EtN}_2\text{O}$ . [ $43^\circ$ ]. (263°).

**Salts.** —  $(\text{B'EtCl})_2\text{PtCl}_4$ : tablets. —  $\text{HgCl}_2 \cdot \text{B'Et}$ : laq.

**Ethylene derivative**  $\text{C}_6\text{H}_9(\text{C}_2\text{H}_5\text{N}_2\text{O})_2$ . [ $151^\circ$ ]. S. 01 at  $24^\circ$ . From ethylene bromide (7 pts.) and the base (2 pts.) at  $170^\circ$ .

**Salt.** —  $\text{B'EtCl}$ : prisms.

**Constitution.**—Since methyl-, ethyl-, and ethylene-oxy-cyanethine are insol. strong potash, it would appear that the alkyls have entered an hydroxyl (E. v. Meyer, *J. pr.* [2] 26, 352). But this is not the hydroxyl corresponding to the  $\text{Cl}$  of chloro-cyanethine, because the product of the action of  $\text{KOEt}$  upon it is a different body to the ethyl-oxy-cyanethine here described. Nevertheless,  $\text{EtI}$  and  $\text{MeI}$  acting upon oxy-cyanethine in presence of alcoholic potash form the above ethyl- and methyl-oxy-cyanethines. The isomeric methoxy-cyanethine from  $\text{MeOK}$  and chloro-cyanethine boils at  $225^\circ$ . The

ethoxy-base boils at  $230^\circ$ . E. v. Meyer thinks the isomerism can be explained thus:

ethoxy-cyanethine  $\text{C}_6\text{H}_{11}\text{N}_2(\text{OEt})$

ethyl-oxy-cyanethine  $\text{C}_6\text{H}_{11}\text{N}_2(\text{NEt})(\text{OH})$ .

**CYANETHINE**  $\text{C}_6\text{H}_{13}\text{N}_2$ . [ $190^\circ$ ]. S. 073 at  $17^\circ$ . S. (alcohol of 90 p.c.)  $5.8$ . According to E. v. Meyer (*J. pr.* [2] 35, 84) cyanethine is not the paranitrile of propionic acid  $\text{C}_3\text{H}_5\text{N}_2$ , since this body, obtained by reducing  $\alpha$ -di-chloropropionic nitrile, has quite other properties.

**Preparation.**—Propionitrile (240 g.) is added gradually to sodium (30 g.), in a flask full of carbonic acid. A violent reaction occurs a few minutes after the addition of each portion. The excess of propionitrile is distilled off. The retort is broken up and the contents treated with water. The insoluble cyanethine is crystallised from 90 p.c. alcohol. The yield is 50 p.c. (Frankland & Kolbe, *C. J.* 1, 69; E. v. Meyer, *J. pr.* [2] 22, 262). One third of the sodium becomes sodio cyanide; for every molecule of sodio cyanide formed one molecule of ethane is given off. If ether be used as a diluent, there is formed an intermediate product  $\text{Me.CH.Na.CN}$ , which on being treated with water yields an oil which gradually crystallises, and has the same percentage composition as cyanethine, but is polymeric with it [ $48-1$ ] ( $253^\circ$ ). The compound  $\text{Me.CH.Na.CN}$ , heated with propionitrile to  $150^\circ$ , yields cyanethine (E. v. Meyer, *J. pr.* [2] 37, 412).

**Properties.**—Monoclinic crystals (from alcohol).

**Reactions.**—1. With *ethyl iodide* at  $160^\circ$  forms  $\text{B'EtI}$ , a syrup, whence by moist  $\text{Ag}_2\text{O}$  an alkaline liquid may be got, and on adding  $\text{HCl}$  and  $\text{PtCl}_4$ , a well crystallised double salt  $(\text{B'EtCl})_2\text{PtCl}_4$  is obtained. But if the iodide be treated with  $\text{Ag}_2\text{O}$ , and the resulting alkaline solution be shaken with ether, the latter is found to contain ethyl-cyanethine  $\text{C}_6\text{H}_{11}\text{EtN}_2$ . [ $45^\circ$ ]. (260°).—2. Excess of strong *hydrochloric acid* converts it into cyanethine  $\text{C}_6\text{H}_{11}\text{N}_2 + \text{H}_2\text{O} + \text{HCl} = \text{H}_2\text{NCl} + \text{C}_6\text{H}_{11}\text{ON}$ . It is precipitated by ammonia.—3. This same body is formed by passing  $\text{N}_2\text{O}$  into a solution of cyanethine in glacial acetic acid.—4. With  $\text{ClCO}_2\text{Et}$  it forms cyanethine carboxylic ether  $\text{C}_6\text{H}_{11}\text{N}_2\text{NH}(\text{CO}_2\text{Et})$ . This is a solid which melts at a low temperature and boils at ( $217^\circ$ ). It is converted by boiling alkali into cyanethine, alcohol, and  $\text{CO}_2$ . Its aqueous solution gives, with  $\text{AgNO}_3$ , a pp.  $\text{C}_6\text{H}_{11}\text{N}_2\text{NAg}(\text{CO}_2\text{Et})$ , aq. Cyanethine carboxylic ether is decomposed by aniline with formation of an anilide  $\text{C}_6\text{H}_{11}\text{N}_2\text{NH.CO.NHPh}$  [ $184^\circ$ ]. This is a very stable body, not decomposed by hot alcoholic potash, but when heated in a current of  $\text{HCl}$  it gives off phenyl cyanate, becoming cyanethine

$\text{C}_6\text{H}_{11}\text{N}_2\text{NH.CO.NHPh} = \text{C}_6\text{H}_{11}\text{N}_2\text{NH}_2 + \text{CO.NHPh}$  (E. v. Meyer & Riess, *J. pr.* [2] 80, 115).—5. Combines at  $100^\circ$  with phenyl cyanate

$\text{C}_6\text{H}_{11}\text{N}_2\text{NH}_2 + \text{CONPh} = \text{C}_6\text{H}_{11}\text{N}_2\text{NH.CO.NHPh}$ .

**Salts.** —  $\text{B'EtCl}$  aq. —  $\text{B'EtPtCl}_4$ . —  $\text{B'EtNO}_3$ : large prisms, neutral to litmus.

**Combination.** —  $\text{B'AgNO}_3$  (at  $120^\circ$ ): crystalline pp.

**Mono-acetyl derivative**  $\text{C}_6\text{H}_{11}\text{AcN}_2$ . [ $59^\circ$ ].

**Tri-chloro-cyanethine**  $\text{C}_6\text{H}_9\text{Cl}_3\text{N}_2$ . [ $110^\circ$ ] Obtained by passing  $\text{Cl}$  into a solution of cyanethine in chloroform. Resembles tri-bromo-

cyanethine in its properties.  $N_2O_3$  passed into its solution in glacial acetic acid forms tri-chloro-oxy-cyanconine  $C_6H_3(OH)Cl_3N_2$ , [132°]. This latter may be reduced by HI to the oxy-cyanconine.

Bromo-cyanethine  $C_6H_3BrN_2$ , [153°].

**Preparation.**—Cyanethine (30 g.) is dissolved in HBr and an equivalent of Br (30 g.) is added. A perbromide of hydrobromide of cyanethine separates as an oil, which soon solidifies. The whole is heated in sealed tubes at 100° for 5 hours. On cooling, crystals of the hydrobromide of bromocyanethine separate. The base is got by adding  $NH_3$  to an aqueous solution of these crystals (C. Riess, *J. pr.* [2] 30, 146).

**Properties.**—Needles. Penetrating odour; v. sl. sol. water.

**Salts.**— $B'HNO_3$ , Trimetric.— $(B'HCl)_2PtCl_4$ ,  $-B'HClAuCl_3$ ,  $-B'HB$ .

**Reactions.**—1. Boiled with alcoholic NaOEt it forms ethoxy-cyanethine (q. v.).—2. Fuming HCl at 200° displaces amidogen by hydroxyl, the product being  $C_6H_3BrN_2(OH)$ , [171°]. The salts of this bromo-oxy-cyanconine are decomposed by water.—3. With aniline at 200° it forms  $C_6H_3(NPhH)N_2$ , phenyl-amido-cyanethine. This is insol. water, but crystallises from alcohol in plates, [125°].—4. Zinc and HCl reduce it to cyanethine.—5.  $N_2O_3$  passed into its solution in glacial HOAc forms bromo-oxy-cyanconine [172°] (E. v. Meyer, *J. pr.* [2] 26, 358).

**Tri-bromo-cyanethine**  $C_6H_3Br_3N_2$ , [126°]. This is formed when bromine acts on cyanethine dissolved in chloroform. It forms pearly plates insol. water, sol. alcohol, ether, and chloroform. It dissolves in strong acids, but is reprecipitated by water. By passing  $N_2O_3$  into a solution of the base in glacial acetic acid, the corresponding 'tri-bromo-oxy-cyanconine' may be formed:  $C_6H_3(OH)Br_3N_2$ , [149°].

**Iodo-cyanethine**  $C_6H_3IN_2$ , [152°].

**Preparation.**—Iodine simply combines with cyanethine, forming a per-iodide. Substitution takes place in presence of  $HNO_3$ , as follows: cyanethine (1 pt.) is dissolved in excess of dilute  $H_2SO_4$ , iodine ( $1\frac{1}{2}$  pt.) is added, and then the liquid is digested on the water-bath while conc.  $HNO_3$  is run in until all the iodine has disappeared. From the filtrate NaOH throws down iodo-cyanethine.

**Properties.**—Sol. acids and dilute alkalis. Decomposed by boiling NaOH.

**Salt.**— $B'HClAuCl_3$ .

**Reactions.**—1. Iodine added to its acid solutions throws down glittering green plates of a periodide.—2. Unlike the chloro- and bromo-derivatives, it is not affected by passing  $N_2O_3$  into its solution in glacial acetic acid.—3. Nevertheless fuming  $HNO_3$ , acting upon its solution in glacial acetic acid, does produce iodo-oxy-cyanconine:  $C_6H_3IN_2(OH)$ . This may be crystallised from alcohol. It melts at [157°].—4. Dilute  $HNO_3$  or conc. HCl (at 180°) convert iodo-cyanethine into oxy-cyanconine,  $C_6H_3(OH)N_2$ , [156°] (Riess, *J. pr.* [2] 30, 168).

**Methyl-cyanethine**  $C_6H_3MeN_2$ , [74°] (o. 257°). From cyanethine and MeI at 160° (E. v. Meyer, *J. pr.* [2] 26, 348). V. sol. water, forming an alkaline solution from which it may be extracted by ether. It separates as an oil when its solution, saturated in the cold, is warmed.

Cyanethine itself is very slightly soluble. Methyl-cyanethine affects the brain-cells, producing muscular contraction. Chloral, chloroform, and morphia are antidotes.

**Combinations.**— $B'_2AgNO_3$ . Pp. sol. hot water, separating as plates.— $B'(HCl)_2PtCl_4$ .

**Reaction.**—1. Heated with HCl at 180° it splits up into methylamine and oxy-cyanconine:  $C_6H_3N_2(NHMe) + H_2O = C_6H_3N_2(OH) + NH_4Me$ .

**Methoxy-cyanethine**  $C_6H_3(OMe)N_2$ , aq. [130°]. Resembles ethoxy-cyanethine in preparation, properties, and salts. It also exchanges  $NH_3$  for OH when acted on by  $N_2O_3$ , the product being the mono-methyl derivative of di-oxy-cyanconine  $C_6H_3(MeO)N_2(OH)$ . This forms the salts:  $B'HClAuCl_3$ ,  $-C_6H_3Ag(MeO)N_2(OH)$  (C. Riess, *J. pr.* [2] 30, 153).

**Ethoxy-cyanethine**  $C_6H_3(OEt)N_2$ , [115°].

**Preparation.**—From sodio ethylate and bromo-cyanethine (Riess, *J. pr.* [2] 30, 148).

**Properties.**—Trimetric plates. Sublimes at 100°. More soluble in acid than in hot water. Its solution is alkaline to test-paper. Separated by KOH from its aqueous solution. Sol. alcohol, ether, chloroform, and acids.

**Reactions.**—1. An aqueous solution of the free base precipitates the hydrates of copper and lead from their salts.—2.  $N_2O_3$  passed into a solution of the base in glacial acetic acid forms the corresponding ethyl derivative of di-oxy-cyanconine:  $C_6H_3(OEt)N_2(OH)$ . This melts at [51°] and forms a silver derivative,  $C_6H_3Ag(OEt)N_2(OH)$ .—3. Heated with conc. HCl at 200°, it appears to form di-oxy-cyanconine:  $C_6H_3(OH)N_2$ , [151°], a silver salt,  $C_6H_3Ag(OH)N_2$ , being analysed.

**Salts.**— $(B'HCl)_2PtCl_4$ ,  $-(B'HCl)AuCl_3$ .

**Combinations.**— $B'AgNO_3$ .

**CYANETHOLINE** v. supposed Ethyl ether of Normal CYANIC ACID.

**CYANHYDRIC ACID** HCN. (*Hydrocyanic acid*. Prussic acid. *Formonitrile*.) Mol. v. 26.98. [−15°]. (For melting-points of mixtures of HCN and  $H_2O$  v. Gautier, *A. Ch.* [4] 17, 120). (26.5°). S.G. (Liquid) at 7° = 7058, at 18° = 6969. V.D. .966 at 40°, .942 at 77°, .936 at 96°, .924 at 158°, .903 at 198° (Gautier, *A. Ch.* [4] 17, 119).  $\mu_D = 1.263$  at 17° (Bussy a. Buignet, *A. Ch.* [4] 3, 231).  $\mu_D$  for mixture of HCN and  $H_2O$  (17°) (B. a. B., l.c.); ratio  $2HCN:H_2O = 1.282$ ,  $2HCN:2H_2O = 1.297$ ;  $2HCN:3H_2O = 1.306$ ,  $2HCN:4H_2O = 1.308$ . H.F. [C, N, H] = −27,480; [C<sup>+</sup>N<sup>−</sup>H<sup>+</sup>] = 10,740; H.C. [ONH, O] = 158,620 (*Th.* 2, 389). Heat of neutralisation [HCNAq, NaOHaq] = 2,770 (*Th.* 1, 295). H.V. = 5,700 (Berthelot, *A. Ch.* [4] 6, 432). Hcy is an extremely weak acid; the affinity is so small that the compound can scarcely be classed as an acid (v. Ostwald's *Lehrbuch der allgemeinen Chemie*, 2, 849). Contraction of volume occurs on mixing with water;  $v$  = vol. of HCN,  $v'$  = vol. of  $H_2O$ ,  $v''$  = vol. of mixture; then (B. a. B., l.c.).

Ratio of HCN:H <sub>2</sub> O	$\frac{v+v'-v''}{v+v'}$
2:1	.0328
2:1.5	.0541
2:2	.0608
2:2.5	.0611
2:3	.0623
2:3.5	.0585
2:4	.0468

Lowering of temperature occurs on mixing with water (B. a. B., *l.c.*).

Ratio of HCN:H <sub>2</sub> O	Fall of temp.
2:1	8.5
2:1.5	9
2:2	9.25
2:2.5	9.25
2:3	9.75
2:3.5	8.25
2:4	7.75

Maximum contraction and maximum fall of temperature occur when the acid and water are mixed in the ratio 2HCN:3H<sub>2</sub>O.

Vapour-pressure of liquid HCN at 18.25° = 472 mm. (B. a. B., *l.c.*).

Prussic acid was discovered by Scheele in 1782; it was examined by Berthollet, Proust, and others; the pure acid was prepared by Gay-Lussac in 1821 (*A. Ch.* 77, 128; 95, 136).

**Occurrence.**—In tobacco-smoke (Vogel a. Reischauer, *D. P. J.* 148, 231; Vohl a. Eurenberg, *A.* 147, 130). Among the products of oxidation of many carbon compounds by HNO<sub>3</sub> (Gill a. Mensel, *Z.* 1869, 65). As a product of the action of KMnO<sub>4</sub> on thialdine and analogous compounds, also of boiling NaOHAq on aromatic nitro-compounds (Guarreschi, *B.* 12, 1699; Post a. Hübner, *B.* 5, 498). As a product of the distillation with water of parts of plants containing *amygdalin* (*q. v.* vol. i. p. 205).

**Formation.**—1. By subjecting cyanogen and hydrogen to the electric discharge (Boillot, *C. R.* 76, 1132); or by heating the mixture to 500°–550° (Berthelot, *Bl.* 33, 2); or by dissolving cyanogen in water and allowing to stand (Wöhler, *P.* 15, 627; *v. also* CYANOGEN).—2. By the action of the induction-spark on a mixture of acetylene and nitrogen (Berthelot, *C. R.* 67, 1141; Dewar, *Pr.* 29, 188; 80, 85), or on a mixture of N with hydrocarbons which yield C<sub>2</sub>H<sub>2</sub> (Berthelot, *l.c.*; Perkin, *C. N.* 21, 66).—3. By rapidly heating NH<sub>4</sub> formate or formamide with P<sub>2</sub>O<sub>5</sub> (Lorin, *A.* 132, 255; Handl, *W. A. B.* 32, 252; 42, 747; Hofmann, *J. pr.* 91, 61).—4. By burning moist methylamine (Tollens, *Z.* 1866, 516).—5. By passing CHCl<sub>3</sub> vapour with NH<sub>3</sub> through a hot tube, or by heating CHCl<sub>3</sub> and alcoholic NH<sub>3</sub> to 180°–190° (Heintz, *A.* 100, 369); or by mixing CHCl<sub>3</sub> with KOHAq and NH<sub>4</sub>Aq (Hofmann, *A.* 144, 116).—6. By decomposing Hg(CN)<sub>2</sub> by HClAq or H<sub>2</sub>SO<sub>4</sub>Aq, preferably in presence of NH<sub>4</sub>Cl, and purifying by passing through CuCO<sub>3</sub> and CaCl<sub>2</sub> (Gay-Lussac; Bussy a. Buignet, *A. Ch.* [4] 3, 250).—7. By decomposing Hg(CN)<sub>2</sub> by H<sub>2</sub>S, or by shaking with H<sub>2</sub>SO<sub>4</sub>Aq and Fe filings.—8. By decomposing AgCN by HClAq.

**Preparation.**—1. A cold mixture of 12 parts water with 9 parts H<sub>2</sub>SO<sub>4</sub> is poured on to 8 parts coarsely powdered K<sub>2</sub>Fe(CN)<sub>6</sub> in a capacious flask; the flask is connected with two bottles containing calcium chloride placed in a bath of cold water; the exit tube from the bottles passes into a dry flask surrounded by snow and salt. The mixture is warmed, and HCN passes into the CaCl<sub>2</sub>-bottles; after about  $\frac{1}{2}$  hour the water surrounding the CaCl<sub>2</sub>-bottles is warmed to 80° or so, when dry HCN passes into the flask in the freezing mixture, and is there liquefied (Pessina, *Traité de Pharmacie de Soubeiran*, 2, 387; *cf.*

Wöhler, *A.* 73, 218). Great care must be taken, as HCN is frightfully poisonous; the CaCl<sub>2</sub> used should be dissolved (after use) in a large quantity of water, HCN is evolved during solution. If HCN<sub>2</sub>Aq is to be prepared, 10 parts K<sub>2</sub>Fe(CN)<sub>6</sub> may be distilled with about 4 parts H<sub>2</sub>SO<sub>4</sub>, and a convenient quantity of water in a flask with very good condenser; the distillate may be rectified by distilling over MgO.—2. A solution of HCN of determined strength can be prepared by mixing KCN and tartaric acid in the ratio KCN:H<sub>2</sub>C<sub>4</sub>H<sub>4</sub>O<sub>6</sub> with a measured volume of water; HCN<sub>2</sub>Aq and KH<sub>2</sub>C<sub>4</sub>H<sub>4</sub>O<sub>6</sub> are formed, almost the whole of the latter is ppd. If 4 parts pure KCN are added to 9 parts tartaric acid in 60 parts water, and shaken in a stoppered bottle nearly filled by the liquid, and then allowed to stand for 12 hours, the liquid contains 3.6 p.c. HCN (Clarke, *A.* 1, 44; *cf.* Liebig, *A.* 41, 288).

**Properties.**—A mobile, colourless liquid, having a peculiar and very penetrating odour; does not redden litmus; *intensely poisonous*; one drop of the anhydrous acid is instantly fatal if swallowed. Inhalation of minute quantities of vapour suffices to kill, even when mixed with air the vapour is extremely poisonous; soluble in water, alcohol, and ether (for temperature and volume changes on dissolving in water, *v. ante*). Evaporation in air suffices to freeze part of the acid, crystals thus formed are transparent orthorhombic prisms. HCN or HCN<sub>2</sub>Aq is unstable; brown, humus-like products are formed (*v. also* Reactions No. 2); addition of traces of formic acid or a mineral acid serves to prevent this decomposition. Burns in air with blue flame. HCN<sub>2</sub>Aq is a very weak acid; its affinity is almost nothing; cyanides are generally very easily decomposed by acids.

**Reactions.**—1. Passed through a tube heated to dull redness, H, CN, C, and N are formed (Deville a. Troost, *J.* 1863, 307); heated to about 100° HCN forms a black mass, which at a higher temperature gives NH<sub>3</sub> and NH<sub>4</sub>CN (Girard, *C. R.* 83, 344); passed over red hot iron HCN is decomposed into H<sub>2</sub>C and N (Gay-Lussac, *A. Ch.* 95, 200).—2. Even in the cold HCN or HCN<sub>2</sub>Aq easily undergoes change; brownish, humus-like bodies are formed; according to Gautier (*A. Ch.* [4] 17, 119) perfectly pure HCN does not undergo change, but if a trace of NH<sub>3</sub> is present decomposition proceeds with formation of *azulmic acid* (*q. v.* vol. i. p. 429). Traces of alkali hasten the decomposition of HCN (hence if the CaCl<sub>2</sub> used for drying contain CaO the acid produced soon begins to change), traces of acids retard the change; among the products is the polymeride H<sub>3</sub>C<sub>3</sub>N<sub>3</sub> (*v.* TRICYANHYDRIC ACID, p. 302). In presence of water NH<sub>4</sub> formate is produced.—3. A series of electric sparks passed through HCN causes partial decomposition to N and C<sub>2</sub>H<sub>2</sub> with separation of a little C, after a time the C<sub>2</sub>H<sub>2</sub> and N begin to recombine. An electric current passed through HCN<sub>2</sub>Aq evolves H at the negative electrode with formation of cyanide of the metal forming the positive electrode; if the HCN<sub>2</sub>Aq is conc. and mixed with H<sub>2</sub>SO<sub>4</sub>, CO<sub>2</sub> and NH<sub>3</sub> are produced (Schlagdenhaufen, *J.* 1868, 306).—4. Mixed with oxygen, and brought to a flame, violent explosion occurs with production of CO<sub>2</sub>, H<sub>2</sub>O, N, and traces of HNO<sub>3</sub>.—5. Potassium permanganate in alkaline solution oxidises

HCONaQ to HCONaAg (Péan de Saint-Gilles, *A. Ch.* [3] 55, 374).—6. *Chlorine* reacts with HCN in daylight to form  $C_2N_2O_4$ ; with HCONaQ it forms CNCl and HCl (Bischoff, *B.* 5, 80). According to Wurtz (*A.* 79, 280) Cl also forms  $C_2N_2Cl_2CNH$ ; if the HCN is in alcoholic solution a crystalline compound  $C_2H_5ClN_2O_4$  is said to be produced (cf. Wurtz, *l.c.* and Bischoff, *l.c.*).—7. *Bromine* forms CNBr and HBr.—8. *Iodine* with HCONaQ gives CN and HIAg.—9. *Hydrogen* (nascent) forms  $CH_3NH_2$ ; the same compound is produced by passing HCN vapour and H over hot spongy Pt (Mendius, *A.* 121, 129; Linnemann, *A.* 145, 88; Debus, *A.* 128, 200).—10. *Potassium* heated with HCN gives KCN and H.—11. Reaction with water, v. beginning of this article.—12. Heated with *hydriodic acid*, NH<sub>3</sub> and CH<sub>4</sub> are produced (Berthelot, *J.* 1867, 347).—13. *Conc. mineral acids* form formic acid and  $H_2$ ; *boiling solutions of alkalis* react similarly; very conc. HClAg in the cold produces formamide (Claisen, *A. Mat.* 176, 135).—14. With *alkalis* in solution, alkali cyanide is formed; on heating alkali formate and NH<sub>3</sub> are produced.—15. Some *metallic oxides* form cyanides and H<sub>2</sub>O, e.g. ZnO, HgO; others give oxy-cyanides, e.g. PbO, CdO; some evolve cyanogen, e.g. PbO (Liebig, *A.* 35, 3).—16. Some *metallic salts* are decomposed by HCONaQ giving cyanides, e.g. many acetates, some salts of Ag and Cu, some alkaline carbonates.—17. *Alkali polysulphides* form sulphocyanides.

*Combinations.*—1. With water hydrates are perhaps formed, but none has been isolated; the contraction and lowering of temperature (v. beginning of this art.) point to formation of  $2HCN.3H_2O$ ; the change of M. P. on addition of water seems perhaps to indicate a hydrate  $HCN.H_2O$  (Gautier, *A. Ch.* [4] 17, 120).—2. With *hydrogen peroxide* to form oxamide,  $C_2O_2(NH_2)_2$  (Attfield, *C. J.* [2] 1, 94).—3. With *hydrogen* to form  $CH_3NH_2$  (v. *Reactions*, No. 9).—4. With the *haloid acids*: HCN saturated with HCl gas at  $-10^\circ$ , and then heated to  $35^\circ-40^\circ$  forms crystals of  $NCH.HCl$ , insol. ether, sol. water, alcohol, and acetic acid; the dry compound dissociates *in vacuo* (Gautier, *C. R.* 65, 410); dry HCl passed into a mixture of HCN and  $C_2H_5OOC.H$ , at  $-10^\circ$  to  $-15^\circ$  forms white prismatic crystals of  $2NCH.3HCl$ , insol. ether,  $CHCl_3$ , and acetic acid, sol. water with decomposition (Claisen, *A. Matthews*, *B.* 16, 308). The compound  $2NCH.3HBr$  is produced similarly to the hydrochloride (Gal, *C. R.* 61, 643; Gautier, *A. Ch.* [4] 17, 141; C. a. M., *l.c.*). When HI gas is passed into HCN the compound  $NCH.HI$  is formed, crystallises from alcohol in rhombohedra, sublimes at  $300^\circ-400^\circ$  with but slight decomposition; insol. ether, sol. cold water; soon changes to HI and NH<sub>3</sub> formate (Gautier, *C. R.* 61, 380; Gal, *C. R.* 61, 643).—5. With *metallic chlorides*: anhydrous HCN combines with several metallic chlorides with production of much heat; the compounds are decomposed by water; the following have been obtained: (1)  $TiCl_3.2NCH$  (Wöhler, *A.* 73, 226); (2)  $SnCl_4.2NCH$  (Klein, *A.* 74, 85); (3)  $SbCl_3.3NCH$  (Klein, *l.c.*); (4)  $FeCl_3.4NCH$  (Klein, *l.c.*).  $BCl_3$  seems to form a compound with HCN (v. Martins, *A.* 109, 81). 6. HCN combines directly with very many

*aldehydes*, e.g. with acetic aldehyde it forms  $C_2H_5O.NCH$  (v. the different *aldehydes*).

*Detection and Estimation.*—1. Addition of KOHAQ followed by  $FeSO_4$  containing some ferric salt pppts. Prussian blue mixed with  $Fe(OH)_2$  and  $Fe(OH)_3$ ; addition of HCl dissolves the  $Fe$  hydroxides and leaves Prussian blue. If there be very little HCN or cyanide present, a blue-green liquid is formed, which on standing deposits bluish flocks. This test will detect  $\frac{7}{100}$  grain of HCN in a very dilute liquid (Taylor, *A.* 65, 263).—2. To the liquid to be tested are added a few drops of yellow  $NH_4$  sulphide, the liquid is evaporated on the steam-bath,  $(NH_4)SCy$  is thus formed; a few drops of water are added and a drop of  $FeCl_3$ Ag, when blood-red  $Fe(SCy)_3$  is formed. This test will detect  $\frac{3}{100}$  grain HCN in a very dilute liquid (Taylor, *l.c.*).—3.  $AgNO_3$ Ag pps. white  $AgCN$ , e. sol.  $NH_4$ Ag, unblackened by light, sol. conc. boiling  $HNO_3$ , with evolution of  $CO_2$ . Other tests are founded on (1) the insolubility of  $Cu_2(CN)_2$  in dilute HClAg (Lassaigne, *A. Ch.* 27, 200); (2) the production of a blood-red colour on heating KCNAg with picric acid (Braun, *Fr.* 1864, 464; Vogel, *C. C.* 1866, 400); (3) the blue colour produced by Cu salts with tincture of guaiacum in presence of HCN (Schönbein, *Fr.* 1869, 67; Vogel, *l.c.*; Eckmann, *Fr.* 1870, 429; Link, a. Möckel, *Fr.* 1878, 455). Insoluble cyanides may be fused with dry  $Na_2S_2O_8$ , dissolved in water, and tested with  $FeCl_3$ Ag (Fröhde, *C. C.* 1863, 698). In cases of suspected poisoning, HCN is separated by distillation after acidifying the matter with tartaric acid. (For details, a manual of analysis must be consulted.)

HCN may be estimated by ppg. as  $AgCN$ , from solutions slightly acidulated by  $HNO_3$ , by addition of  $AgNO_3$ ; haloid acids must be absent; the pp. is washed, dried at  $100^\circ$ , and weighed. Liebig's volumetric method may be used when haloid acids are present (*A.* 77, 102); the solution is made strongly alkaline by KOHAQ, and standardised  $AgNO_3$ Ag is added until a permanent turbidity is produced; the compound  $AgK(CN)_2$  is produced but remains dissolved until addition of excess of silver forms insoluble  $AgCN$ . 1 c.c. of decinormal silver solution (10.8 grams Ag per litre) =  $\frac{1}{1000}$  gram HCN.

*Constitution.*—Cyanhydric acid may be (1) HCN or (2) HNC; formula (1) represents the atom of H as directly associated with the C atom, while formula (2) represents the atoms of H and N as directly associated. The reactions of this acid with alkalis show that the H atom is acidic; the fact that the acid combines directly with the haloid acids favours the formula  $N.CH$ , which suggests the properties of a derivative of  $NH_3$ . The formation of the acid by the reaction of  $CHCl_3$  with KOHAQ is in keeping with the formula  $N.CH$ ; this formula also suggests the production of  $CH_3NH_2$  by the reaction of hydrogen with  $N.CH$ ; the production of  $H.CO.NH_2$  when cyanhydric acid reacts with  $H_2O$  cannot decide between the formulae  $N.OH$  and  $C.NH$ . On the whole cyanhydric acid is best regarded as the nitrile of formic acid; the formula is written  $N.CH$ .

*POLYMERIDE OF CYANHYDRIC ACID. Tricyanhydric acid.*  $H_3C_3N_3$ . Produced by spontaneous polymerisation of HCN, or of conc. HCONaQ, in

presence of alkalis, also from KCN (Lange, B. 6, 99; Wippermann, B. 7, 767; Lescœur a. Rigault, C. R. 89, 310). Prepared by treating the brown substance produced when HCN is allowed to change in air, with much ether, crystallising, dissolving in ether, shaking with animal char, crystallising, and re-crystallising from hot water. Triclinic crystals; v. sol. alcohol, less sol. ether. Solubility in water 55 at 31°, 5.5 at 100°. Begins to decompose at 140°, melts at about 180°, and deflagrates at a higher temperature. When slowly heated with water forms HCN and the products of decomposition of this acid ( $\text{H}_2\text{CO}_3$ ,  $\text{H}_2\text{NH}_2$ , &c.). Heated with  $\text{BaOAc}$ , with  $\text{HClAc}$ , or  $\text{HIAc}$ , produces  $\text{CO}_2$ ,  $\text{NH}_3$ , and glycocholl (Wippermann, B. 7, 767); hence tricyanhydric acid appears to be the nitrile of amido-malonic acid,  $\text{CN.CH}(\text{NH}_2).\text{CN}$  (cf. Bayer, A. 131, 297).

#### DICYANHYDRIN v. DI-CYANO-PROPYL ALCOHOL.

**CYANIC (SULPH<sup>9</sup>) ACID. SULPHOCYANIC ACID AND POLYMERIDES.** (*Thiocyanic acid. Hydro-sulphocyanic acid. Sulphocyanhydric acid. Sulphocarbimide.*) Only one isomeride of the composition  $\text{HCNS}$  is known, and it is probably normal sulphocyanic acid  $\text{HS.CN}$ ; the acid  $\text{HN.CS}$  has not been isolated although ethereal salts derived from it are known. A polymeride of sulphocyanic acid, viz.  $\text{H}_3\text{S.N.C.}_n$ , is known, and the methylic salt of trisulphocyanic acid ( $\text{H}_3\text{C.N.S.}_3$ ) is also known (cf. CYANIC ACID).

The metallic salts of the form  $\text{M.SCN}$  are described as **SULPHOCYANIDES** in the article **CYANIDES**.

**Preparation.**—1. Dilute solutions of  $\text{H.SCN}$  are obtained by distilling excess of a sulphocyanide with dilute  $\text{H}_2\text{SO}_4$ ; more conc. solutions are obtained by distilling  $\text{K.SCN}$  with conc.  $\text{H}_3\text{PO}_4$ , or by the reaction of  $\text{H}_2\text{S}$  with  $\text{Hg}(\text{SCN})_2$  or  $\text{Pb}(\text{SCN})_2$  (Hermes, J. pr. 97, 465; Zimmermann, A. 199, 1). 2. Sulphocyanic acid is obtained by gently heating a small quantity of  $\text{Hg}(\text{SCN})_2$  in a stream of dry  $\text{H}_2\text{S}$  (Wöhler, G. A. 69, 271); explosions may occur if large quantities are used (Hermes, *loc. cit.*).

**Properties.** A colourless, strongly smelling, liquid; crystallises when surrounded by snow and salt. An aqueous solution containing 12.7 p.c. of the acid has S.G. 1.04 at 17° (Hermes, *loc. cit.*).  $\text{HSCy}$  is a very strong acid; the affinity is nearly equal to that of  $\text{HCl}$  (v. Ostwald's *Lehrbuch der allgemeinen Chemie*, 2, 849).

**Reactions.**—1. Decomposed by heat to HCN and persulphocyanic acid ( $\text{H}_2\text{C}_2\text{N}_2\text{S}_3$ ). Stable in dilute aqueous solution (about 5 p.c.); the anhydrous acid polymerises on standing. On distilling the aqueous acid the greater part is vapourised unchanged. —2. Heated with mineral acids, is decomposed to HCN and  $\text{H}_2\text{C}_2\text{N}_2\text{S}_3$ , or to  $\text{CO}_2$ ,  $\text{NH}_3$ , and  $\text{CS}_2$ , or  $\text{H}_2\text{S}$ ; the products of decomposition vary with the concentration of the solution of  $\text{HS.CN}$  used (cf. Volckel, A. 43, 74). 3. Decomposed by sulphuric acid ( $\text{H}_2\text{S}$ ) to  $\text{CS}_2$  and  $\text{NH}_3$  (Volckel, *loc. cit.*). —4. Oxidisers, e.g.  $\text{KMnO}_4$ , produce HCN and  $\text{H}_2\text{SO}_4$  (Péan, C. R. 46, 626). —5. With zinc and sulphuric acid, reacts to form  $\text{H}_2\text{S}$ ,  $\text{NH}_3$ ,  $\text{NH}_4(\text{CH}_3)$ , and  $(\text{CH}_3)_2\text{S}$  (Hofmann, B. 1, 179). —6. Heated with fairly conc. sulphuric acid,  $\text{COS}$  and  $\text{NH}_3$  are produced (Than, A. Suppl. 5, 286). —7. Organic

acids react to form  $\text{COS}$  and amides, or sometimes nitriles, e.g.  $\text{H.S.CN} + \text{C}_2\text{H}_5\text{O.OH} = \text{COS} + \text{C}_2\text{H}_5\text{O.NH}$  (Letts, B. 5, 669; Kekulé B. 6, 113).

The metallic salts of sulphocyanic acid are described as **SULPHOCYANIDES** under **CYANIDES**. The ethereal salts of normal sulphocyanic acid of the type  $\text{Et.S.Cy}$ , are described as **ETHYL, &c. SULPHOCYANIDE**; the ethereal salts derived from isosulphocyanic acid, of the type  $\text{Et.N.CS}$ , are described as **ETHYL, &c., THIO-CARBIMIDE**.

#### POLYMERIDES OF SULPHOCYANIC ACID.

**I. Disulphocyanic acid  $\text{H}_2\text{S}_2\text{C}_2\text{N}_4$**  (Fleischer, A. 179, 201). Prepared by adding alcoholic solution of  $\text{KOH}$  to persulphocyanic acid ( $\text{H}_2\text{C}_2\text{N}_2\text{S}_3$ ), obtained by adding 3 vols.  $\text{H}_2\text{SO}_4$  S.G. 1.34, to conc.  $\text{NH}_4\text{SCNAc}$ , and crystallising the crystals which separate from hot water; the crystals which separate are  $\text{K}_2\text{C}_2\text{N}_2\text{S}_2$ , they are collected and decomposed by dilute  $\text{H}_2\text{SO}_4$ ; the acid separates as a wax-like yellow mass, which hardens after a time. Sol. alcohol, nearly insol. water; when the solution is heated  $\text{HSCN}$  is formed.

**II. Trisulphocyanic acid**; this acid is not known, but its methylic salt,  $\text{Me}_3\text{S}_3\text{C}_3\text{N}_6$ , is obtained along with methyl thiocarbimide [ $\text{Me.N.CS}$  (q. v.)], by heating  $\text{Me.S.Cy}$  to 180° (Hofmann, B. 13, 1349).

For metallic salts of disulphocyanic acid v. **CYANURATES AND SULPHOCYANURATES**, p. 360.

#### CYANIC, DICYANIC, AND TRICYANIC ACIDS and their derivatives.

**HISTORICAL INTRODUCTION.**—Very soon after his inquiry into the constitution of Prussian Blue, an investigation which had enriched science with the discovery of Prussic Acid, Scheele (1786, *Opuscula* 2, 76) conducted a series of experiments with a view to determine the nature of a specimen of urinary calculus. The calculus happened to be of the acid variety. The outcome of this work was the discovery of Uric and Cyanuric or Pyro-uric acids. This is the earliest record of an oxygen compound of cyanogen. Scheele, however, did not realise that he had in his hands a hitherto unknown chemical compound. Distilling some of the calculus he obtained amongst other products a brown sublimate, which admitted of purification by resublimation. The properties of this sublimate are those now known to belong to cyanuric acid. Moreover, cyanuric acid may be obtained by the mode of procedure described. To Scheele the sublimate appeared to resemble succinic acid. Pearson (1798, Tr. 34) repeated these experiments, and observed in addition most of the characters of cyanuric acid known at the present day, but, like Scheele, this observer did not recognise the sublimate as a new substance, and was content to note its similarity to benzoic acid. Henry (1818, Thomson's *Système de Chemie*, 2, 198) was the first to point out the independent nature of the acid, and the earliest analysis was made by Chevallier and Lassaigne (1820, A. Ch. 13, 155).

At the same time that the cyanuric acid of Scheele was being studied, the first observations were made of three important classes of compounds—the fulminates, the cyanates, and the thiocyanates. Brugnatelli (1798, A. Ch. 27, 831) prepared 'Fulminating Silver,' which, however,

he regarded as oxalate, and Howard (1800, *Tr.* 204) about the same time described the manufacture and properties of 'Fulminating Mercury.' That sulphur is capable of combining directly with potassium cyanide, forming 'Thiocyanate,' was first distinctly observed by Porret (1814, *Tr.* 527), the reaction having been studied previously by Buchholz (1798, *Beitrag zur Erweiterung und Berichtigung der Chemie*, 1, 88). The prediction of Gay-Lussac of a class of cyanates was verified by Vauquelin (1818, *A. Ch.* 9, 115, 22, 134), who found Ammonium Cyanate among the products of the spontaneous decomposition of cyanogen in water.

The discovery of the first compound of cyanic acid was soon followed by that of other cyanates and of the acid itself. Wöhler (1822-24, *G. A.* 71, 95; 73, 157; *P.* 1, 117) analysed many of these, including the silver salt, from which he derived the formula of the acid. A little later, when heating some cyanuric acid, this chemist noticed that a gas was given off, having a peculiar pungent odour. This proved to be free Cyanic Acid, and by a suitable cooling apparatus Wöhler succeeded in liquefying it. The free cyanic acid thus obtained was examined in an important memoir by Liebig and Wöhler (1830, *P.* 20, 369), and its constitution established so far as the exigencies of the time required. Liebig reverts to this question again in 1838 (*A.* 26, 122), pointing out that cyanic acid does not form double salts and is monobasic.

In the meantime a study of the fulminating mercury of Howard had furnished Liebig with some interesting results. These were published in 1823 (*G. A.* 75, 893) and in conjunction with Gay-Lussac in Paris in 1824 (*A. Ch.* 25, 285). From the silver salt, which was obtained in a condition sufficiently pure, the composition, molecular weight, and basicity of fulminic acid were ascertained. The free acid was, however, not isolated. Later (1838, *A.* 26, 122) Liebig points out the relation of fulminic acid to its isomerides, cyanic and cyanuric acids. It is shown to form double salts and to be dibasic.

In the hands of Berthollet (1787, *A. Ch.* 1, 35) and Gay-Lussac (1815, *A. Ch.* 90, 200) chlorine had been made to act upon prussic acid with the formation of gaseous Cyanogen Chloride. Serullas (1828, *A. Ch.* 38, 390), now employing the same agents in the presence of sunlight, obtained a crystalline solid now known to be Cyanuric Chloride. By the prolonged action of water this compound was found to decompose, forming hydrochloric acid and a new solid, named by Serullas Cyanic Acid. This cyanic acid was perceived to be quite distinct from the cyanic acid of Wöhler, but Serullas does not seem to have compared it with the pyro-uric acid of Scheele. Nevertheless, the properties noted by Serullas agree in all respects with those given by Pearson for Scheele's acid. The analysis made by Serullas, though not inaccurate for the time, entirely overlooked the hydrogen.

Wöhler made the next step forward by the discovery of a new compound, Cyanuric Acid, among the products of the action of heat on urea (1829, *P.* 15, 622). This cyanuric acid was at once compared both with the pyro-uric acid of Scheele and with the cyanic acid of Serullas. Its properties were found to agree with both of

the earlier known substances, and when careful analyses were made of all three they proved to be identical. The subject is finally discussed by Liebig and Wöhler (1830, *P.* 20, 369), where it is suggested that the term cyanuric acid should be adopted for the single compound whether obtained by the distillation of uric acid (Scheele), the action of water on cyanuric chloride (Serullas), or the action of heat on urea (Wöhler); and that the name cyanic acid should be retained for the pungent liquid which Wöhler had found as a decomposition product of cyanuric acid, and of which Vauquelin had previously prepared the ammonium salt.

The question of the constitution of cyanic acid and its isomerides is the subject of another memoir by Liebig (1838, *A.* 26, 145). The basicity of cyanuric acid, which had been a matter of controversy between Wöhler and Liebig, is finally decided by the discovery of a triargentic salt, and it is shown to have the formula  $H_3C_3N_3O_3 \cdot 2H_2O$ . The analogy is pointed out between the acids of phosphorus as elucidated by Graham (1833, *Tr.* 253) and the three isomerides:—monobasic cyanic acid  $HCNO$ , dibasic fulminic acid  $H_2C_2NO$ , and tribasic cyanuric acid  $H_3C_3NO$ .

The Thiocyanic Acid, of which Porret prepared the potassium salt, was isolated by Wöhler in 1829 (*G. A.* 69, 271), and in the same year Liebig (*P.* 15, 563) came across a solid substance among the products of the action of water on cyanuric chloride which, in conjunction with Wöhler, he found again (1830, *P.* 20, 386) as a product of the decomposition of cyanic acid with water. This compound isomeric with cyanuric acid, but insoluble, was called 'insoluble cyanuric acid' or, later, Cymelide.

About this time, too, Liebig (1834, *A.* 10, 10) by acting on ammonium thiocyanate by heat produced a substance called Melam, and from this, by the action of dilute soda, a base was formed richer in the elements of ammonia. This base was regarded by Liebig as the amide of cyanuric acid, and was called from its parent substance Melamine (1834, *A.* 10, 18). Another base nearly related to these, Mellone, was obtained by the action of heat on melam, and from mellone, by treatment with nitric acid Liebig (1834, *A.* 10, 34) prepared an acid, Cyanilic Acid, which proved to be an isomeride of cyanuric acid, distinguished from the latter acid chiefly by its crystalline form and solubility.

The thirty-five years following 1840 were very largely devoted to the discovery of ethereal derivatives of cyanic and cyanuric acids, and to a study of their structure with a view to rendering intelligible the very remarkable metameric series of compounds which were brought to light. But aside from this main current of research there are many other discoveries of scarcely less importance. Two of these call for attention at once—the study of the action of heat on nitrate of urea by Pelouze (1842, *A.* 44, 106) and Wiedemann (1848, *A.* 68, 324), and the interesting reaction between cyanic acid and aldehyde whereby Liebig and Wöhler (1846, *A.* 59, 296) prepared the compound known as Trigenic Acid.

Three important series of alkyl derivatives were discovered during the years 1847-48; the cyanic and cyanuric ethers of Wurtz, and the thiocyanic ethers of Cahours. By acting

on alkyl potassium sulphate with a salt of cyanic acid, Wurtz (1848, *C. R.* 26, 368; '27, 241) obtained Alkyl Cyanates, and using a cyanurate instead of a cyanate he succeeded in preparing a series of Alkyl Cyanurates. Both these classes of ethers when decomposed by water, in presence of dilute acids or alkalis, give amines and carbon dioxide, showing that they have a similar structure. The discovery of the ethers of Wurtz was partly anticipated by Cahours (1847, *A. Ch.* 18, 261), who by the analogous reaction of alkyl calcium sulphate with potassium thiocyanate obtained Alkylthiocyanates. The thiocyanic ethers do not admit of their constitution being studied by decomposition with water, but the same end is attained if they be subjected to the reducing action of nascent hydrogen. The thioethers of Cahours give by this treatment mercaptan and hydrocyanic acid, showing that the alkyl radicle is attached to the sulphur and not to the nitrogen.

The study of ethereal derivatives must now give way to the consideration of several new reactions which were brought to light at this time. Debus (1849, *A.* 72, 18) in his work on ethyl thiocarbamate or xanthogenamide  $\text{NH}_4\text{CS.OEt}$  or  $\text{NH}_4\text{CO.SEt}$  was led to the discovery of a reaction by which this compound breaks down into mercaptan and cyanuric acid. If the constitution of xanthogenamide were better known, an important insight might thus be obtained into that of cyanuric acid. Notwithstanding the attempts of Bineau (1839, *A. Ch.* 70, 251) to prepare an amide of cyanic acid homologous with the cyanuramide or melamine of Liebig, no such compound was isolated until Cloëz and Cannizzaro instituted their inquiry in 1851 (*C. R.* 32, 62). These chemists obtained Cyanamide by acting upon cyanogen chloride with ammonia. A very remarkable property of the cyanamide thus obtained is the ease with which it undergoes polymerisation. The result of this intramolecular rearrangement, as shown by Bailstein and Geuther (1858, *A.* 108, 99; 123, 241) is the formation of the dicyanogen homologue Dicyandiamide. An isomeric series of homologous amides is thus completed corresponding to the three classes of mono-, di-, and tri- cyanogen compounds. Employing amines instead of ammonia in the reaction of Cloëz and Cannizzaro, the alkyl cyanamides were prepared by Cahours and Cloëz (1854, *C. R.* 38, 354).

Another instance of polymerisation was announced at this time by Liebig (1855, *A.* 95, 282). When fulminating mercury is allowed to stand in presence of water it gradually changes its colour and other properties. These changes were found to correspond to an entire rearrangement of the molecule, the dicyanic fulminic acid having polymerised to tricyanic Fulminuric Acid. The new acid is metameric with cyanuric acid, but in its basicity and in other respects it is quite distinct from that compound. Fulminuric acid was discovered independently by Schischkow (*A.* 97, 63; 101, 213), whose attention was also directed to the constitution of the isomeric fulminic acid from which it is derived. Mercuric fulminate, according to Schischkow (*J. R.* 16, 276), is  $\text{Hg}(\text{CN})_2 \cdot \text{C}_2(\text{NO})_2 \cdot \text{Hg}$ , and fulminic acid  $(\text{HCN})_2 \cdot \text{C}_2\text{H}_2\text{N}_2\text{O}_2$ . On the other hand Kekulé (*A.* 101, 200; 105, 279), in view of

other reactions, regarded fulminic acid as nitro-acetonitril  $\text{CH}_3\text{NO}_2\text{CN}$ .

Returning once more to the ethers, a reaction must be noticed that was first studied by Cloëz (1857, *C. R.* 44, 482), which in the hands of Hofmann and other later investigators has done much to give order to the knowledge of cyanic derivatives. Cloëz caused cyanogen chloride to act on sodium ethylate, and obtained a compound which he called Cyanetholine and which has sometimes been regarded as consisting of a cyanic ether isomeric with that of Wurtz. Gal (1866, *C. R.* 61, 527), who observed its decomposition products, correctly so regarded it, and moreover judged that it was related to the cyanic ethers of Wurtz in the same manner that the nitriles are related to the isonitriles.

Still another reaction was announced at this time for the preparation of ethers. Halich a. Limpriecht (1859, *A.* 109, 111) discovered that silver cyanurate and alkyl iodides react, forming cyanuric ethers identical with those of Wurtz.

The Cloëz reaction was now, in 1870, the subject of an important investigation by Hofmann and Olshausen (*B.* 3, 269). No cyanic ether was found, but, instead, these observers succeeded in preparing a series of Cyanuric Ethers metameric with those of Wurtz. The methyl analogue of the cyanetholine of Cloëz and Gal proves to be a mixture containing cyanuric ether and an amido-derivative. Cyanic ethers homologous with these cyanuric ethers and metameric with the cyanic ethers of Wurtz have never been isolated. Hofmann and Olshausen were led to predict the formation of a series of cyanuric ethers in this reaction from its analogy to that of Cloëz and Cannizzaro for cyanamide and Cahours and Cloëz for alkyl cyanamides, thus:—

Now in the second reaction the alkyl cyanamide was known to polymerise readily at the moment of its formation to alkyl melamine. Just in the same manner, thought Hofmann and Olshausen, might the product of the third reaction, which differs only in containing oxygen for imidogen, polymerise at the moment of its formation to a cyanuric ether. This hypothesis was confirmed by experiment.

The cyanuric ethers thus obtained when submitted to the action of water in presence of dilute acids or alkalis give cyanuric acid and alcohol, showing that the alkyl radicle is attached to the oxygen and not to the nitrogen, as it would seem to be in the case of the Wurtz ethers. It would thus appear that the Wurtz ethers are substituted imide compounds, while those of Hofmann and Olshausen are substituted hydroxyl derivatives. The reaction of both with water then becomes clear, thus:—

Hofmann and Olshausen.

Wurts.

The difference between these two classes of ethers may be represented by the formulae:—

or better still by the use of ring formulae, a device which is especially useful when more complex reactions have to be studied. The ether corresponding to the hydroxyl acid is of course the normal or ortho-ether, while the imide substituted ether is the iso-ether:—

Normal ether of Hofmann and  
Olshausen.

Iso-ether of Wurtz.

In the same manner the normal cyanic ether which in the Cloëz reaction is probably formed in the first instance, but which has not been isolated, may be supposed to be related to the cyanic ether of Wurtz:—

(CN).OR'  
Hypothetical normal cyanic  
ether.

(CO).NR'  
Isocyanic ether of  
Wurtz.

And the decomposition by water of the two ethers may be represented:—

A very interesting instance of intramolecular change was announced by Hofmann and Olshausen in this same memoir. It was noticed that the melting-point of trimethyl normal cyanurate changed on continued heating. In the first place it melts at 132°, but after heating for some time the melting-point rises and remains constant at 175°. Metastasis was suspected, and it was found that, while before the application of heat the cyanurate gave when decomposed with water alcohol and cyanuric acid, after that operation its decomposition products were carbon dioxide and amine. The normal ether had changed into the corresponding iso-ether of Wurtz. Such instances of intramolecular migration from normal to iso- in the case of alkyl derivatives of cyanogen compounds are now known to be of frequent occurrence.

Of the thio-analogues of these isomeric ethers, one series had been discovered by Cahours. On reduction with nascent hydrogen they gave mercaptan and hydrocyanic acid. These were the analogues of the hypothetical normal cyanic ethers. The series of isomeric thiocyanates corresponding to the cyanic ethers of Wurtz were synthesised by Hofmann (1868, *B.* 1, 25 a. 169; 2, 452; 7, 814; 8, 106), and constitute the 'mustard oils' of which ordinary mustard oil is a member. When the mercury salt of mono-alkyldithiocarbamic acid is distilled it loses mercuric sulphide, and sulphuretted hydrogen and alkyl thio-isocyanate passes over. The thio-isocyanic ethers give on treatment with nascent hydrogen not mercaptan and hydro-

cyanic acid but amines and thio-aldehyde. The two reactions may be seen thus:—

Normal thio-ether of Cahours. Isothio-ether of Hofmann.

The following discoveries also belong to this period:—The production of isocyanic ethers from isonitriles by direct oxidation accomplished by Gautier (1863, *C. R.* 67, 804). The discovery of Dicyanic Ethers and Alkyl Melamines by Hofmann (1861, *A. Suppl.* 1, 54; *B.* 3, 765; 1869, *B.* 2, 602; 3, 264). The former by polymerisation of phenyl-isocyanate in presence of triethyl-phosphine, and the latter by desulphurisation of monoalkylthio-urea in which case alkyl cyanamide is doubtless first formed and then changed into the polymeric melamine. Finally, the experiment of Beilstein (1860, *A.* 116, 357), which showed that cyanuric acid treated with phosphorus pentachloride gives cyanuric chloride. Cyanuric chloride is thus seen to be related to cyanuric acid precisely in the same way as acetyl chloride for example is related to acetic acid. It may be obtained from the acid by substitution of its hydroxyl by chlorine when treated with phosphorus pentachloride, and, as Serullas was the first to show, the chloride by treatment with water loses its chlorine and again assumes hydroxyl in its place, becoming cyanuric acid.

A period is now reached, commencing about the year 1875 and extending to the present day, during which the activity of investigators in this subject has been directed in the main to the question of the constitution of cyanic and cyanuric acids. To these must be added melamine, for just as the acids give rise each to two parallel series of metameric ethers, so, as it will appear, does melamine. This isomerism has not yet been found among the alkyl cyanamides or dicyanic diamides. It will be seen that in the case of the parent hydrogen compounds no reactions have been discovered which permit, as in the case of their alkyl derivatives, the assertion that the one is normal or of the hydroxyl type, and the other iso- or of the imide type.

The discussion was inaugurated by Nencki (1876, *B.* 9, 232), who, working on the compound aceto-guanidine, found that by a series of reactions it is converted finally into cyanuric acid. In a second communication (*B.* 9, 244) he suggested an explanation of these reactions assuming the imide nature of cyanic acid. This procedure led of course to the view that cyanuric acid is iso- or imide in its constitution. Further evidence in favour of the imide structure of both cyanic and cyanuric acids is found according to Fleischer (*B.* 9, 436) in the desulphurisation of ammonium thiocarbamate  $\text{NH}_2\text{CO.SNH}_2$ , by which reaction either urea or iso-cyanate should result: experiment showed that ordinary ammonium cyanate was formed. Weith (*B.* 9, 454) then joined the controversy, and proposed an altogether new set of formulae for the compounds obtained by Nencki from aceto-guanidine. Nevertheless, while pointing out that the imide nature of the acids was not proven, he considered the weight of evidence to be in favour of that view. Michler (*B.* 9, 716) advanced another reaction to support the iso-

theory, the distillation of *u*-diphenylurea, which yields cyanic acid and diphenylamine. This reaction has, however, no more value as proof than the action of heat on urea itself.

So far the evidence had been very largely in favour of the iso-hypothesis. Claus (*B. 9, 721*) now joined issue with the preceding observers. He questioned the value of the little understood guanidine reactions of Nencki as proof of constitution, and showed, as Weith had indeed already done, that with equally probable assumptions the changes observed by Nencki might be explained so as to support the opposite view. Similarly he contended against Fleischer that the formula for ammonium thiocarbamate is by no means established, and if the alternative hydroxyl formula,  $\text{NH}_2\text{CS.OH}$ , be used, the reaction supports the normal hypothesis. To these criticisms both Nencki and Fleischer replied, Fleischer (*B. 9, 988*) defending the formula which he had employed for thiocarbamic acid, and Nencki (*B. 9, 1008*) considering at length the evidence for and against the two contending theories. The leading points are as follows: For the imide or iso-formula.—1. The easy breaking down of cyanic acid by the action of water into ammonia and carbon dioxide  $\text{CONH} + \text{OH}_2 = \text{CO}_2 + \text{NH}_3$ .—2. The conversion of cyanic acid into formamide by the action of nascent hydrogen  $\text{CO.NH} + \text{H}_2 = \text{H.CO.NH}_2$ .—3. The reaction of Wurtz in which cyanates and cyanurates yield iso- and not normal ethers  $(\text{CON})\text{K} + \text{K}'\text{R}'\text{SO}_4 = \text{CONR}' + \text{K}_2\text{SO}_4$ . For the hydroxyl or normal formula.—1. If in order to explain all the reactions of these bodies it is found necessary to assume an intra-molecular change, it is easier to imagine it taking place from the normal to the iso- than from the iso- to the normal atomic arrangements, since it is known with what ease normal cyanic and cyanuric derivatives change to the iso- condition, and thus to suppose that in the Wurtz reaction normal ether is at first formed and that it immediately changes to iso-ether.—2. Finally, Beilstein had shown that cyanuric chloride, the normal structure of which does not admit of question, is the chloride corresponding to cyanuric acid. Nencki admits that the acetoguanidine reactions tell equally for both theories. Nencki concludes, however, with Weith that the weight of evidence is in favour of the imide structure. The discussion was continued by Claus (*B. 9, 1165*), Fleischer (*B. 9, 1459*), and Nencki (*B. 9, 1552*), but little further advance was made.

The fundamental distinction between mono-, di-, and tri-cyanic acids which Liebig so clearly pointed out has been confirmed, and its value appreciated more and more. It may be that fulminic acid is not the dicyanic acid homologous with cyanic and cyanuric acids, and that this has yet to be discovered. Indeed, there may be many such mono-, di-, and tri-cyanogen series to which the numerous isomerides of cyanic acid of which the constitution is at present so little known will contribute members.

By the help of this conception a place is ready for the Thiodicyanic Acid discovered in 1876 by Fleischer (*A. 179, 204*), and perhaps for several new isomerides of cyanic acid which have now to be noticed. It was just at this time that Herzig (*B. 12, 170*) announced the

discovery of  $\alpha$ - and  $\beta$ -Cyanuric Acids. These new acids were said to be obtained by the action of hexabromacetone on urea. It has, however, recently been shown (Senier, *C. J. 49, 693; 49, 743*) that both these acids are merely ordinary cyanuric acid disguised by traces of impurities. The isomerism of the cyanamido-carbonic acid discovered by J. Meyer (1878, *J. pr. 18, 419*) is merely coincidental, that compound having nothing further in common with cyanuric derivatives. Four isomerides, however, remain to be noted, all derived from fulminic acid. The first is Isofulminuric Acid. It was prepared by Ehrenberg (1884, *J. pr. 30, 38*) by acting on an ethereal solution of free fulminic acid with ammonia. The remaining three isomerides were discovered by Scholvin (1885, *J. pr. 32, 461*), and all arose out of the action of dilute sulphuric acid on fulminates. They are Meta-fulminuric Acid,  $\beta$ -Iso-fulminuric Acid, and Iso-cyanilic Acid. Metallic salts of each were described, but no alkyl or other derivatives.

In the present state of their history it would be premature to speculate as to the constitution of this remarkable group of isomerides. It may, however, be worth while to bear in mind that the possible metameres of cyanuric acid are very great, especially when mixed types are considered, as, for instance, the two conceivable intermediate acids between normal and iso-cyanuric acid (*cf. Senier, Inaug. Dissert., Berlin, [1887] 28*).

A further study of these fulminuric acids may help to clear up the constitution of fulminic acid itself, for like the latter acid some of them evolve hydroxylamine when decomposed by water in presence of hydrochloric acid. It was on this account that Steiner (1883, *B. 16, 1481*) suggested the following isonitroso-formula for

fulminic acid  $\begin{array}{c} \text{C}=\text{NOH} \\ | \\ \text{C}=\text{NOH} \end{array}$ , whereas he had previously (1876, *B. 9, 782*) been an adherent of

Kekulé (1857, *A. 101, 200; 105, 279*), who regarded it as nitroacetnitrile. The recent work of Divers (1885) (*C. J. 47, 79*) has led to another

formula  $\begin{array}{c} \text{N}=\text{CH} \\ | \\ \text{O} < \text{N}=\text{COH} \end{array}$ . According to Armstrong,

the essential facts are best represented for the present by one of the following,  $\begin{array}{c} \text{C}=\text{OH} \\ | \\ \text{N} < \text{C}=\text{N.OH} \end{array}$

$\begin{array}{c} \text{N}=\text{CH} \\ | \\ \text{O}-\text{C}=\text{N.OH} \end{array}$  (*C. J. 47, 79*).

In the next place two announcements call for notice which have an interesting bearing on the constitution of cyanuric acid. The first is the production of melanurenic acid, a derivative of cyanuric acid, by Bamberger, by the action of water on dicyandiamide (*Inaug. Dissert., Berlin 1880; B. 16, 1074; 16, 1459; 16, 1709*). Bamberger ascribes to dicyandiamide the formula  $\text{C.NH.NH}_2\text{:NECN}$  as preferable to Baumann's formula (1878, *B. 6, 1375*),  $(\text{ONH}) < \begin{array}{c} \text{NH} \\ | \\ \text{NH} \end{array} > (\text{CNH})$ .

The second is the study of the absorption spectrum of cyanuric acid which led Hartley (1882, *C. J. 41, 48*) to the conclusion that it has a ring formula and doubly-linked atoms. This is of

course quite in accord with the normal or hydroxyl theory.

There remain to be considered the important researches of Hofmann, Klason, Ponomareff, Mulder, and Rathke. These investigations are for the most part contemporaneous. They also largely supplement one another; and although they do not explicitly support the same hypothesis, they do not take the form of a discussion. Only an outline of the more important features of this work can be attempted here.

Commencing with Mulder in the year 1832: the Cloëz reaction was the first to engage the attention of this observer (*R.* 1, 41, 191; 2, 133; 3, 287). The results in the ethyl series were similar and parallel to those in the methyl series of Hofmann and Olshausen. The most interesting observation is that normal cyanic and cyanuric ethers give bromine addition compounds, while the isocyanic and cyanuric ethers form no such combinations. This, according to Mulder, becomes a test by which the one structure can be distinguished from the other. Now cyanuric acid does not combine with bromine, and hence it is regarded as iso- in constitution. The compound with cyanuric ethyl ether has the formula  $C_3N_3O_3Et_3Br_3$ . By the use of this test Mulder was led in 1835 to recognise the diethyl cyanuric ether of Habich and Limpricht as an iso-compound (*R.* 4, 91). Subsequent observation has, however, not confirmed the value of this reaction as a test in all cases.

Many attempts have been made to discover among the metallic cyanates and cyanurates isomeric differences like those found among the ethers. An investigation of Calmels in 1884 (*C. R.* 99, 239) would seem to show that metallic cyanides analogous to the nitriles and carbamides exist, but hitherto no one has found evidence of a similar isomerism among the metallic cyanates or cyanurates. The experiments of Mulder in 1832 (*B.* 15, 69) with this object proved as fruitless as those of Bannow (1871, *B.* 4, 254; 13, 2201) had been.

Mulder suggested new formulae for bromide and chloride of cyanogen  $N_3CBr$  and  $N_3CCl$ , and in a series of communications in 1835-6 (*R.* 4, 47; 4, 151; 5, 65; 5, 84; 5, 99) studied the properties of the bromide. The curious fact was noted that pure cyanogen bromide does not polymerise, but that this change takes place readily in presence of a trace of free bromine. Two curious addition products of cyanogen bromide with ethyl cyanurate are described  $C_3N_3O_3Et_3BrCN$  and  $C_3N_3O_3Et_3BrCN$  (*cf.* Senier, *Inaug. Dissert.*, Berlin, 1887, 34).

As in the case of Mulder, so the work of Ponomareff commenced with a study of the cyanetholine of Cloëz. This chemist in 1832 (*B.* 15, 513) arrived at results in accordance with those of Hofmann and Olshausen, and proposed the use of mercuric chloride to distinguish iso- from normal cyanuric compounds. This reagent gives crystalline addition compounds with normal derivatives, that in the case of normal ethylcyanurate being  $(CN)_2SOEt.HgCl_2$ . Unfortunately, like the corresponding bromine test of Mulder, this mercuric chloride test has been shown to be inapplicable to all cases (Hofmann, 1835-6, *B.* 18, 2796; 19, 2098).

The study of the formation of cyanuric ethers

and the preparation of alkoyl derivatives in the hands of Ponomareff threw additional light on their structure. Hofmann and Olshausen had prepared the cyanuric ethers by the Cloëz reaction, using cyanogen chloride. The method was simplified by Ponomareff in 1835 (*B.* 18, 3261), who employed the already polymerised cyanuric chloride. By this means he obtained normal cyanuric ethers which gave cyanuric chloride again when treated with phosphorus pentachloride, and gave melamine by the action of ammonia. In the next place this observer studied the reaction of Habich and Limpricht, by which only isocyanuric ethers had been obtained. By allowing the alkyl iodide to act on silver cyanurate at a low temperature there was always formed together with the isocyanurate some ether that gave a crystalline compound with mercuric chloride, and hence was judged by Ponomareff to be normal ether. The experiment was afterwards repeated by Hofmann and the crystalline mercuric chloride compound examined (1836, *B.* 19, 2093), but it was proved that the mercuric chloride was combined not with normal but with iso-ether. In the same memoir Ponomareff described the first alkoyl derivative of cyanuric acid, triacetyl cyanurate. The corresponding tribenzoyl cyanurate was obtained soon afterwards by Senier (1836, *C. J.* 49, 813).

The reaction between dicyandiamide and carbon dioxide already pointed out as giving rise to a mixed cyanuric acid and melamine, melanurenic acid, was made the basis of an interesting communication from Rathke in 1835 (*B.* 18, 3102). This inquirer noted that when such compounds as  $H_2O$  or  $NH_3$  or  $CO_2$ , which can divide into two divalent radicals, for instance  $H_2 + O$ ,  $H_2 + NH$ , and  $O + CO$ , combine to form addition compounds with cyanogen derivatives, they do so in accordance with a general law, the one residue joining the carbon and the other the nitrogen. Thus nitriles take up the residues of water or sulphuretted hydrogen, giving acid amides or thio-amides, or they take up ammonia or amines forming amidines. To this class of reactions belongs, according to Rathke, the conversion of dicyandiamide into melanurenic acid, and also the parallel reaction announced for the first time between dicyandiamide and thiocyanic acid, where combination to thioammine takes place. Using Bamberger's formula for dicyandiamide, the reactions may be represented thus:—

The bearing of these reactions on the constitution of cyanuric acid and melamine is evident.

Ammeline and melanurenic acids are amido-acids between melamine and cyanuric acid, and if the above expressions be the true ones, both the acid and melamine are imido- or iso- and not normal compounds. The following formulae showing cyanuric acid and melamine both as normal and iso- compounds will assist in making this clear:—

According to Hofmann the weight of evidence is in favour of the view that both these compounds are normal in constitution. Rathke pointed out that these two reactions must be considered, and whether the formula of Bamberger be employed or the alternative one of Baumann, they both lead to the conclusion that thio-ammelne and melanurenic acid are iso-compounds, and indirectly to the iso-nature of cyanuric acid and melamine. One class of reactions requires the one formula, another class of reactions the other. In Rathke's view it is impossible to find a formula to account for both classes of reactions. It seems that the position of the hydrogen atoms, unlike that of the alkyl radicals, is not stable, and that indeed both formulae may be employed side by side. In the same manner Rathke recommends the use of two formulae for hydrocyanic acid, acetic acid, the lactam and lactim groups, thio-urea, and other similar cases.

In another communication (1887, *B. 20*, 1056) this standpoint was developed further, and in view of the discovery of several triphenylmelamines Rathke suggested the addition of a third imide type for alkyl melamines, thus:—

The radicals attached directly to the ring as in the first iso-form are said to be in the *exo*-position, while those attached to side chains as in the second iso-form are termed *exo*-. This system was suggested in order to account for the instances of complex isomerism in the case of

phenylmelamines, which Hofmann was the first to point out. In the communications following, Rathke (1887-8, *B. 20*, 1065; 21, 867; 21, 874) announced several new complex derivatives, the constitution of which he studied by means of this hypothesis. These are Phenyl Thiammeline, Triphenyl Ammeline, Monophenyl Iso-cyanuric acid, Diphenyl Melamine, and Triphenyl Melamine.

No inquirer in this department of chemical research has been more unwearied, and none has been more successful, than Hofmann. As early as 1857, in conjunction with Cahours (*A. 102*, 293), he discovered allyl cyanate, and from that time to this he has reverted to the subject again and again. The earlier communications have been already noticed, but there remain a series of exhaustive critical memoirs which have appeared during the last few years of which only the barest outline can be given. They are an attempt to settle the question of the constitution chiefly of cyanuric acid and melamine, but they bring into their service numerous new reactions and classes of compounds.

In one of the first of these, in 1881 (*B. 14*, 2728), Hofmann described a new reaction in which isethers are among the products. It is the action of heat on alkyl acetyl urea. Together with isocyanic ether di- and tri-alkyl isocyanurate are formed. In another paper in 1880 (*B. 13*, 1349) some interesting instances of intramolecular change are described. Just as the cyanic methyl ether at first formed in the Cloëz reaction was found by Hofmann and Olshausen to polymerise to methyl cyanurate, so the same change is now effected in the case of methyl thiocyanate, which is converted into methyl thiocyanurate, and also (1885, *B. 18*, 765) in that of phenyl isocyanate, which becomes phenyl isocyanurate. The general tendency of the normal to pass over into the more stable iso-atomic arrangement finds another example here, for together with the trimethylthiocyanurate some of the iso-compound is always formed. Hofmann called attention to the fact that pure methylthiocyanate does not polymerise by heat alone, but does so in presence of a little hydrochloric acid. It will be remembered that in the same manner Mulder found that cyanogen bromide only admitted of polymerisation when mixed with some other substance, as, for instance, with free bromine. The action of such agents as hydrochloric acid and free bromine in these instances, and the still more remarkable action of triethylphosphine or pyridine (Snape, 1886, *C. J.* 49, 254), which convert phenyl isocyanate only into dicyanate, while if certain dry salts are substituted, sodium acetate, sodium formate, or sodium carbonate, the intramolecular re-arrangement goes as far as the production of cyanurate; these are facts of which chemistry in its present state of development offers no explanation.

From methylthiocyanurate thus obtained Hofmann isolated in 1885 for the first time free Thiocyanuric Acid (*B. 18*, 2196). The methyl ether, by treatment with sodium sulphide, is converted into the sodium salt, methyl mercaptan being formed at the same time, and the sodium salt, when treated with hydrochloric acid, has its sodium replaced in three stages, forming two intermediate acid sodium thio-cyanurates,

and finally free thio-cyanuric acid. The sodium salt of thio-cyanuric acid may be also prepared from cyanuric chloride by the action of sodium mercaptide.

Pursuing the inquiry still further into the behaviour of this thio- analogue of cyanuric acid, the action of ammonia and amines on the trimethyl ether was investigated in 1885 (*B.* 18, 2755). Water decomposes the ether in accordance with the general reaction into cyanuric acid and mercaptan, and it was thought that ammonia might similarly give mercaptan and melamine, thus:—

Experiment proved this to be the case. Melamine is thus advantageously prepared. The reaction takes place, however, in three stages, two intermediate compounds being formed—mono-amido- and di-amido- ether—thus:—

The action of substituted ammonias was now tried, and corresponding alkyl melamines and intermediate alkyl amido- ethers resulted.

Melamine and alkyl melamines are also produced, as was expected, from cyanuric chloride, and ammonia or amines, and in this case, too, a series of intermediate amido- and alkyl amido- cyanuric chlorides was obtained, thus:—

The second of these intermediate compounds was identified as Liebig's chlorocyanamide (1834, *A.* 10, 43), and its phenylamido- analogue as the compound described by Laurent (1848, *A. Ch.* [3] 22, 97) under the name chlorocyanilide.

The alkyl melamines obtained by these reactions were at once compared with those which Hofmann had himself prepared sixteen years before by desulphurisation of substituted thio-ureas, and were found to be metamersides. Here, then, were two metameric series of alkyl melamines just as there are two series of alkyl cyanates and cyanurates and their thio-analogues. One might be normal and the other iso-, corresponding to the normal and iso- cyanates or cyanurates. Their constitution was now to be solved. It was feared that the action of water would give no clue to the structure of these compounds, because on the assumption of either constitution cyanuric acid and amine would probably be produced. Thus:—

It is true that in the one case the acid at first formed ought to be normal and in the other iso-, but all experience had shown that, whatever might be the constitution of the acid in the first moment of its existence, it was always found when examined to be one and the same cyanuric

acid. Experiment confirmed this expectation, and it became necessary to seek some other method.

This was found by Hofmann in 1885 (*B.* 18, 2781) in a reaction between cyanuric chloride and secondary amines. In this reaction neither melamine nor its primary alkyl derivatives, but secondary alkyl melamines were produced—Hexa-alkyl Melamines. These were prepared, and it was seen that an examination of the decomposition products when acted upon by water would decide whether they were normal or iso- compounds. Thus:—

Here was a distinction that could be observed, and experiment showed that the first equation represents the reaction which takes place. The new alkyl melamines are to be regarded, then, as normal derivatives, and the iso- structure is reserved for the metameric compounds derived from substituted ureas.

What, then, is the constitution of melamine itself? When the close analogy existing between the reactions by which the normal alkyl melamines are produced, and that by which melamine itself may be obtained is perceived, there cannot remain much doubt as to its normal constitution, thus:—

Moreover the normal constitution of cyanuric chloride must not be forgotten. From it are derived only normal ethers, and from normal ethers, as Hofmann himself shows, cyanuric chloride may be reproduced by the action of phosphorus pentachloride. Two subsequent memoirs (*B.* 18, 3217; 19, 2061) contain a description of many new derivatives of normal and iso-cyanuric acid and melamine. Residues in the position which Rathke afterwards proposed to designate by the denomination *eso* are shown to exist in some of these complex derived compounds. This is notably the case with the triphenylmelamine which Hofmann designates unsymmetrical, and which Rathke would term diisotriphenylmelamine. It has the formula

and is composed of two iso-melamine and one normal melamine group. The cyanuric ethers were submitted to a careful re-examination in the first of these papers, and their melting-points and boiling-points re-determined and corrected, and in most cases their crystalline form submitted to exact measurements.

The question of the constitution of cyanuric acid was considered by Hofmann mainly in one of the memoirs already referred to (*B.* 18, 2791). It was pointed out in the first place that the con-

stitution of the normal and iso-series of alkyl derivatives is established beyond question by the perfectly distinct products which they give when subjected to the decomposing action of water. The normal ethers break down into cyanuric acid and alcohol, the iso-ethers into carbon dioxide and amine. So far, then, as the decomposition of the ethers is evidence, cyanuric acid is a normal compound. But, on the other hand, no one has succeeded in preparing normal ethers from cyanuric acid. Iso-ethers, as in the methods of Wurtz and Habich and Limpricht, are always obtained. So far, then, as the formation of the ethers is evidence, cyanuric acid is an iso-compound. Consideration of these reactions leaves the question an open one. Other reactions must be studied. It is argued that cyanuric acid is iso- because of its formation from urea and certain allied compounds; but this assumes a constitution for urea which is by no means finally established; and which, indeed, as Hofmann points out, has been directly questioned. Again to cyanuric acid is assigned the iso- structure, because of its homology with cyanic acid, which is assumed to be iso-. If cyanic acid were really iso- this argument would have great weight; but Hofmann showed, especially by means of its close analogy to normal thio-cyanic acid, that cyanic acid is probably normal in constitution. It is admitted, however, by Hofmann that in order to explain all the reactions, whichever view be accepted, an intra-molecular rearrangement has sometimes to be assumed. For instance, maintaining the normal hypothesis such a change has to be supposed in the case of the reactions of Wurtz and Habich and Limpricht. It is shown, however, that instances of this change from normal to iso- are of frequent occurrence, whereas there is scarcely a case on record—only one which Hofmann himself in a later memoir pointed out—of the opposite change. This then is an argument in favour of the normal hypothesis. But perhaps the strongest of all arguments in support of the normal view is the relation of cyanuric acid to cyanuric chloride. This chloride is, for reasons already given, unquestionably a normal compound. Now phosphorus pentachloride behaves towards normal cyanuric ethers in a manner precisely parallel to its action, as shown by Beilstein, on cyanuric acid itself. In both cases cyanuric chloride results. Again, from cyanuric chloride and alcohol (sodium ethylate) normal ether is obtained, and in the parallel reaction between cyanuric chloride and water (sodium hydroxide) cyanuric acid results. Thus:—

and

This analogy receives important support from the corresponding thio-derivatives. It is scarcely conceivable that intramolecular change takes place in one series of these reactions and not in the other, and indeed the composition of the chloride of iso-cyanuric acid is probably such that it would be impossible for it by metastasis to be converted into cyanuric chloride; at all events Hofmann shows that the action of phosphorus pentachloride on iso- ether leads to the

formation of a chloride having an altogether different composition. In another memoir in 1885 (*B.* 19, 2084) Hofmann continues this discussion. Klason in the meantime had offered another explanation of Rathke's dicyandiamide and thiocyanic acid reaction, which led to the normal and not the iso- structure for thio-arameline. Hofmann adopted this. With regard to the use of more than one formula as suggested by Rathke, Hofmann can only admit this practice if it be meant to imply that a compound behaves in one reaction as if it had one constitution, and in another reaction as if its constitution were a different one. The identity of a substance requires that in its quiescent state it be regarded as one and the same thing. The only way out of the difficulty with regard to the constitution of cyanuric acid is to adopt that formula which explains the most reactions, and to assume in the others that metastasis takes place. Hofmann therefore adopts the view that cyanuric acid is a normal or hydroxyl compound.

There now remain to be considered a series of important communications from the Swedish chemist, P. Klason (or Claesson, as it is written in the Swedish memoirs). The field independently worked out by this observer is covered very largely by that of Hofmann, and has already been noticed. This is true also with regard to the view to be taken of the constitution of cyanic and cyanuric acids and melamine. The leading points which remain must now be briefly stated.

In an early communication in 1885 (*B.* 18, 496 R.) some important improvements were suggested in the preparation of cyanuric chloride, and the discovery of Cyanuric Iodide was announced. A series of normal melamines was described a little later (*B.* 18, 497 R.), and it was shown that thio-ammelime was normal and not iso-, as Rathke had maintained. Klason proved this by its synthesis from Liebig's chlorocyanamide (normal diamido-cyanuric chloride), by the action of sodium sulphhydrate. The fact that cyanamide by polymerisation gives ordinary normal melamine leads to the view that it also is normal (*B.* 18, 499 R.). On the other hand Klason considered the only known series of alkyl cyanamides to be iso- compounds because they polymerise to alkyl iso-melamines. Maintaining the normal structure for cyanic and cyanuric acids Klason (1886, *J.* pr. 33, 126) submitted the reasoning of Nencki and the more recent arguments of Rathke to a detailed criticism. It was shown that another formula can be ascribed equally well to acetoguanidine, and that this leads to the normal formula for cyanuric acid. This is the case also with Rathke's reaction between dicyandiamide and thiocyanic acid, for Klason maintained that the diamide is a normal and not an iso-compound. The case of Bamberger's reaction is admittedly different. In order to explain that reaction, metastasis has undoubtedly to be assumed. Subsequent examination of the melam compounds by Klason (1886, *J.* pr. 33, 285) showed that ordinary melam is a mixture of true melam and a new compound melam, and that ordinary ammelime is a mixture of melanuric acid and ammelime. It was therefore proposed to apply the name ammelide to melanuric acid, in which case the compounds

between cyanuric acid on the one hand and melamine on the other would be as follows:—

cyanuric acid ammeline ammeline melamine.

#### MONOCYANOGEN GROUP.

Normal cyanic acid  $\text{CNOH}$  i.e.  $(\text{C}:\text{N})\text{OH}$ .

**Formation.**—1. By the action of heat on cyanuric acid (Wöhler, *G. A.* 71, 95; 73, 157; *P.* 1, 117; Liebig a. Wöhler, *P.* 20, 369).—2. In place of cyanuric acid a mixture of  $\text{P}_2\text{O}_5$  and urea may be employed (Weltzien, *A.* 107, 219) or a mixture of uric acid with  $\text{MnO}_2$  or  $\text{H}_2\text{SO}_4$  (Döbereiner, *G. A.* 74, 121), or mercuric urate may be heated alone.—3. Cyanic acid is also formed when ethyl thiocarbamate is subjected to distillation.  $\text{CO.NH}_2\text{SEt} = \text{CNOH} + \text{EtSH}$  (Debus, *A.* 72, 1; 75, 127; 82, 253).

Cyanic acid cannot be isolated by treatment of its metallic or alkyl salts with hydrous acids or water, for the moment it is liberated it takes up the elements of water and appears as  $\text{NH}_3$  and  $\text{CO}_2$ .

**Preparation.**—Anhydrous cyanuric acid is heated nearly to redness in a current of  $\text{CO}_2$ . This is conveniently accomplished in a tube bent at right angles, the charged arm of which can be placed in a combustion furnace. The vapour of cyanic acid is led into a suitable condenser surrounded by a freezing mixture. More or less polymeric cyanamide is always formed and condenses as a snow-white solid in the cooler parts of the tube (Wöhler) (Baeyer, *A.* 114, 156).

**Properties.**—A thin colourless liquid which reddens litmus and has an extremely pungent odour suggestive of glacial acetic acid. The vapour causes a copious flow of tears and the liquid applied to the skin quickly raises a blister. S.G. ( $^{\circ}$ ) 1.140; ( $^{-25}$ ) 1.156 (Troost a. Haute-feuille, *J.* 1868, 314). V.D. 1.50 (calc. = 1.49) (T. a. H.). H.C. 98,470 (T. a. H.). Cyanic acid changes readily into the isomeric cyanamide or 'insoluble cyanuric acid.' At  $0^{\circ}$  this transformation takes place quietly in the course of an hour, but at higher temperatures the action becomes explosive. The heat evolved by this atomic rearrangement is 17,630 gram-units (T. a. H., *J.* 1869, 99). In ice-water cyanic acid dissolves without decomposition until a certain degree of concentration is attained.

**Reactions.**—1. In presence of triethyl phosphine it polymerises to cyanuric acid (Hofmann, *C. S. Mem.* 18, 322).—2. Acted on by water it immediately splits into  $\text{NH}_3$  and  $\text{CO}_2$ .—3. Alcohol reacts on cyanic acid forming allophanic ether  $2\text{CNOH} + \text{EtOH} = \text{CO.NH}_2\text{NH.CO.OEt}$ .—4. With epichlorhydrin  $\text{C}_2\text{H}_4\text{OCl}$  it combines to form chloroxypropyl carbamic anhydride

$\text{CO} \begin{array}{c} \text{NH} \\ \diagup \quad \diagdown \\ \text{O} \quad \text{C}_2\text{H}_4\text{Cl} \end{array}$  (Thomsen, *B.* 11, 2136).—5. By the action of aldehyde trigenic acid is produced  $2\text{CNOH} + \text{CH}_3\text{CHO} = \text{C}_2\text{H}_4\text{N}_2\text{O}_2 + \text{CO}_2$  (Liebig a. Wöhler, *A.* 69, 296; Herzog, *M.* 2, 398).—6. Sodium amalgam reacts on  $\text{CNOK}$ , producing formamide (Basarow, *B.* 4, 409).—7. When dry  $\text{HCl}$  is passed over  $\text{CNOK}$  or better  $\text{CNOAg}$

cyanamide is formed and a liquid cyanic acid hydrochloride  $\text{CNOH}\cdot\text{HCl}$  distils over (Wöhler, *A.* 45, 357).—8. With chloral cyanic acid vapour combines to form cyanic acid chloral  $(\text{CCl}_3\text{CHO})\cdot\text{CNOH}$ , and with chloral hydrocyanide it also combines to form the compound  $(\text{CCl}_3\text{CHO.HCN})\cdot\text{CNOH}$  (Bischoff, *B.* 5, 86; Cech, *B.* 8, 1174; 9, 1253; 10, 880; Wallach, *B.* 8, 1327).

#### HALOGEN DERIVATIVES.

Cyanogen chloride  $\text{CNCl}$  i.e.  $(\text{C}:\text{N})\text{Cl}$ .

**Formation.**—By the action of  $\text{Cl}$  on aqueous hydrocyanic acid (Berthollet, *A. Ch.* 1, 35; Gay-Lussac, *A. Ch.* 90, 200), or on certain metallic cyanides in presence of water (Serullas, *A. Ch.* [2] 35, 291, 337; cf. Wöhler, *A.* 73, 219; Cahours a. Cloëz, *A.* 90, 97; Cloëz, *A.* 102, 354; Klein, *A.* 74, 85; Martius, *A.* 109, 79; Langlois, *A. Ch.* [3] 61, 481).

**Preparation.**—About 15 grams of  $\text{Hg}(\text{CN})_2$  are placed in a 3-litre bottle and partly covered with water.  $\text{Cl}$  is then led in till the whole of the air is displaced, and the bottle is set aside in a dark place for 24 hours. The colour of the  $\text{Cl}$  gradually disappears, its place being taken by colourless gaseous cyanogen chloride. Several such bottles may be charged and set aside at the same time. For most purposes the gas thus prepared may be at once made use of. If, however, it is desired to isolate the pure chloride the bottle must be placed in a freezing mixture, when crystals of  $\text{CNCl}$  form, and these by a series of operations are separated in a pure state (Serullas) (Wöhler). Explosions having sometimes occurred by the above method (Weith, *B.* 7, 1745), the reaction between aqueous  $\text{HCN}$  kept in a freezing mixture and  $\text{Cl}$  is preferred by some chemists (Gautier, *A.* 141, 122). In any case the greatest care is requisite, on account of the extremely poisonous nature of this gas, to prevent its escape into the atmosphere of the laboratory.

**Properties.**—At ordinary temperatures it is a colourless gas with a pungent odour and irritating action on the eyes. Exceedingly poisonous. At  $-12^{\circ}$  to  $-15^{\circ}$ , or at  $0^{\circ}$  under a pressure of 4 atmospheres, it condenses to a colourless liquid, and at  $-18^{\circ}$  it crystallises in prisms. V.D. = 2.124 (calc. = 2.128) (Salet, *A.* 136, 144; cf. Wurtz, *A.* 79, 284; Regnault, *J.* 1863, 65, 67, 70). C.H. (Berthelot, *J.* 1871, 79; 1874, 114). Polymerises spontaneously but gradually into  $(\text{CN})_2\text{Cl}_2$ . S. 25; 50 (ether), 100 (alcohol). The aqueous solution does not redden litmus, and gives no pp. with  $\text{AgNO}_3$ .

**Reactions.**—1. Potassium heated in  $\text{CNCl}$  gas gives  $\text{KCN}$  and  $\text{KCl}$ , and antimony in a similar manner forms a chloride and liberates cyanogen. 2. With aqueous  $\text{KHO}$  it is converted into  $\text{CNOK}$  and  $\text{KCl}$ .—3. Alcohols dissolve  $\text{CNCl}$ , and on standing a reaction gradually takes place with the formation, among other products, of carbonic and carbamic ethers (Wurtz).—4. With sodium alkylates  $\text{CNCl}$  reacts, forming, in the first instance, normal cyanic ethers, which, however, immediately polymerise to the corresponding cyanuric compounds (Cloëz, *C. R.* 44, 482; Hofmann a. Olshausen, *B.* 3, 271).—5. With ammonia cyanamide and  $\text{NH}_4\text{Cl}$  are formed, and in the same manner alkyl ammonias form alkyl cyanamides (Cloëz a. Cannizzaro, *A.* 78, 229; 90, 95).

**Combinations.**—1. With other halogen compounds:  $\text{SbCl}_5\text{CNCl}$  (Klein, *A.* 74, 87);  $\text{BCl}_3\text{CNCl}$  (Martius, *A.* 109, 79);  $\text{Fe}_2\text{Cl}_2\text{CNCl}$  (K.);  $\text{TiCl}_4\text{CNCl}$  (Wöhler, *A.* 73, 220);  $\text{EtCNONCl}$  (Henke, *A.* 106, 296); the compound  $(\text{CNCl})_2\text{HCN}$  (Wurtz, *A.* 79, 281) is said not to exist (Vogt, *A.* 155, 170).—2. With  $\text{NH}_4\text{OH}$ ,  $\text{HCl}$ ,  $\text{PH}_3\text{HI}$ ,  $\text{CO}_2\text{NH}_2$ , &c. (Traube, *B.* 18, 462).

**Cyanogen bromide**  $\text{CNBr}$  *i.e.*  $(\text{C}\cdot\text{N})\cdot\text{Br}$ .

**Formation.**—By the action of Br on  $\text{Hg}(\text{CN})_2$  (Serullas, *A. Ch.* [2] 34, 100; 35, 294 a. 315) or on  $\text{HCNAg}$  (Löwig, *Das Brom und seine chemischen Verhältnisse*, Heidelberg, 1829, 69), or on a cold solution of KCN (Langlois, *A. Ch.* [3] 61, 482).

**Preparation.**—When 1 part of Br is allowed to flow gradually on 2 parts of  $\text{Hg}(\text{CN})_2$  in a retort surrounded with ice  $\text{CNBr}$  and  $\text{HgBr}_2$  are formed with great evolution of heat. The  $\text{CNBr}$  sublimes in needles, contaminated at first with free Br, but ultimately the Br flows back and enters completely into combination. Gentle heat is then applied, and the  $\text{CNBr}$  sublimes into a receiver surrounded with ice (Serullas).

**Properties.**— $\text{CNBr}$  sublimes in colourless needles, which afterwards change to cubes (S.). [ $+4^\circ$ ] (Löwig); [above  $16^\circ$ ] (S.); [not even at  $40^\circ$ ] (Bineau, *A. Ch.* [2] 68, 425); [ $48^\circ$ ] (Senier, *priv. com.*); [ $52^\circ$ ] (Mulder, *R.* 4, 151). ( $61^\circ$ ) (750 mm.) (M.). H.F. (Berthelot, *J.* 1871, 80). Vapour pungent and irritating, resembling  $\text{CNCl}$ . V. sol.  $\text{H}_2\text{O}$  and alcohol. Forms a crystalline hydrate less fusible than the anhydrous compound.

**Reactions.**—1. Heated in a closed tube from  $130^\circ$ – $140^\circ$  it is converted into  $(\text{CN})_2\text{Br}_2$ .—2. With  $\text{KIO}_4\text{aq}$  it forms  $\text{KBr}$ ,  $\text{KCN}$ , and  $\text{KBrO}_3$  (S.) (L.). 3. Ammonia gas reacts with the formation of  $\text{CNNH}_3$  and  $\text{NH}_4\text{Cl}$ .

**Cyanogen iodide**  $\text{CNI}$  *i.e.*  $(\text{C}\cdot\text{N})\cdot\text{I}$ .

**Formation.**—By the action of I on mercuric, silver, or other metallic cyanides (Davy, *G. A.* 54, 384; Wöhler, *G. A.* 69, 281; Serullas, *A. Ch.* [2] 27, 184; 29, 184; 34, 100; 35, 293 a. 344; Van Dyk, *R. P.* 21, 223).  $\text{CNI}$  sometimes occurs as an impurity in commercial iodine (Scanlan, *C. S. Mem.* 3, 321; F. Meyer, *Ar. Ph.* [2] 51, 29; Klobach, *Ar. Ph.* [2] 60, 34).

**Preparation.**—1. Iodine is dissolved in a warm conc. solution of KCN until the liquid, on cooling, solidifies to a crystalline mass. On gently heating the  $\text{CNI}$  sublimes, and it may be purified by recrystallisation from alcohol or ether (Liebig, *Chim. Org.* 1, 180).—2. 2 pts. of iodine dissolved in ether are added to 1 pt. of  $\text{Hg}(\text{CN})_2$ . Reaction takes place, and the  $\text{CNI}$  goes into solution in the ether, from which it may be obtained by evaporation (Linnemann, *A.* 120, 36).

**Properties.**—Long, delicate, colourless needles, or from its solution in alcohol or ether in four-sided laminae (Herzog, *Ar. Ph.* [2] 61, 129). It has a pungent, penetrating odour and acrid taste. It is very poisonous. Sol. water, more sol. alcohol, still more sol. ether and volatile oils. No one has hitherto succeeded in converting it into the polymeric  $(\text{CN})_2\text{I}_2$ . H.F. (Berthelot, *J.* 1871, 79; 1874, 114) (*cf.* E. Meyer, *J. pr.* [2] 36, 292).

**Reactions.**—1. KHO reacts, forming KCN, KI, and  $\text{KIO}_3$  (Serullas).—2.  $\text{NH}_3$  converts it

into  $\text{CNNH}_3$  and  $\text{NH}_4\text{I}$ .—3. With  $\text{ZnBr}_2$  or  $\text{AlBr}_3$ , alkyl nitriles and metallic iodides are formed (Calmels, *Bl.* 43, 82).—4. It dissolves in alkaline sulphites with the formation of HI, HCN, and alkaline sulphates (Strecker, *A.* 148, 95).

**Combinations.**—When 4 pts. of I are dissolved in a solution of 1 pt. of KCN in 2 pts. of water long colourless crystals separate, which after recrystallisation from ether have the composition  $\text{KI}_4\text{CNI}$ , *aq.* [ $120^\circ$ – $130^\circ$ ] (Langlois, *A. Ch.* [3] 60, 220).

**METALLIC DERIVATIVES v. CYANATES**, p. 297.

**ALKYL DERIVATIVES.** *Normal cyanic ethers.* Normal cyanic ethers have never been isolated. The reaction between sodium alcoholate and cyanogen chloride (Clöez, *C. R.* 44, 482), which was supposed to yield normal cyanic ethers, proved when further investigated, both in the methyl series (Hofmann a. Olshausen, *B.* 3, 271) and in the ethyl series (Mulder, *R.* 2, 133), to give no cyanic ether, but instead a mixture of alkyl cyanurate and amido-derivatives. There is not much doubt that in this reaction normal cyanic ethers are formed in the first instance, but they polymerise almost immediately to their cyanuric homologues (*cf.* Ponomareff, *B.* 15, 515; Mulder, *R.* 1, 210; 3, 306).

**ALKOYL DERIVATIVES.**

**Acetyl cyanate**  $\text{C}_2\text{H}_3\text{NO}$  *i.e.*  $(\text{C}\cdot\text{N})\cdot\text{OAc}$ .

Silver cyanurate acts upon acetyl chloride, forming what is probably a polymeric form of this compound. When this is subjected to distillation liquid acetyl cyanate or cyanogen acetate is obtained, together with acetonitrile and cyanogen. Water decomposes it into acetamide and  $\text{CO}$  (Schützenberger, *A.* 123, 271).

**Normal thiocyanic acid v. THIOCYANIC ACID.**

**Normal cyanamide**  $\text{CH}_2\text{N}_2$  *i.e.*  $(\text{C}\cdot\text{N})\cdot\text{NH}_2$ .

**Formation.**—1. By the action of  $\text{CNCl}$ ,  $\text{CNBr}$ , or  $\text{CNI}$  on  $\text{NH}_3$ .  $\text{CNCl} + 2\text{NH}_3 = \text{CNNH}_2 + \text{NH}_4\text{Cl}$  (Bineau, *A. Ch.* [2] 67, 368; 70, 251; Clöez a. Cannizzaro, *A.* 78, 229).—2.  $\text{CINN}_3\text{Na}$  is the end product of the reaction between  $\text{NH}_3\text{Na}$  and  $\text{CO}_2$ .

(a)  $\text{NH}_3\text{Na} + \text{CO}_2 = \text{NH}_2\cdot\text{CO}\cdot\text{ONa}$ .

(b)  $\text{NH}_2\cdot\text{CO}\cdot\text{ONa} = \text{CNONa} + \text{H}_2\text{O}$ .

(c)  $\text{CNONa} + \text{NH}_2\text{Na} = \text{CINN}_3\text{Na} + \text{H}_2\text{O}$

(Beilstein a. Gauthier, *A.* 108, 93; Drechsel, *J. pr.* [2] 16, 203).—3. By the action of sodium on urea, ammonium carbamate, or ammonium carbonate  $\text{CO}(\text{NH}_2)_2 + \text{Na} = \text{CNNH}_2 + \text{H} + \text{NaHO}$  (Fenton, *C. J.* 41, 262).—4. By desulphurisation of thio-urea by means of  $\text{HgO}$ .  $\text{CS}(\text{NH}_2)_2 - \text{H}_2\text{S} = \text{CNNH}_2$  (Volhard, *J. pr.* [2] 9, 25; Baumann, *B.* 6, 1371; Mulder a. Smit, *B.* 7, 1636).

**Preparation.**—Moist freshly ppt. mercuric oxide, which has been purified by boiling with  $\text{NaHOaq}$  and then with water, is added in small portions at a time to an unsaturated cold solution of thio-urea in water. Excess of  $\text{HgO}$  is avoided, otherwise insoluble mercuric cyanamide is formed (Engel, *Bl.* 21, 273). The operation is continued until all the thio-urea is desulphurised, which may be ascertained by the liquid ceasing to give a black pp. when a drop of it is tested with  $\text{NH}_4\text{AgNO}_3$ . The sulphide pp. is then filtered off and the filtrate concentrated as quickly as possible by evaporation, the latter part of the process being conducted in a vacuum over  $\text{H}_2\text{SO}_4$ . From the residue, ether extracts cyanamide and leaves dicyandiamide, which is also formed, undissolved (Volhard; Drechsel, *J. pr.*

## CYANIC, DICYANIC, AND TRICYANIC ACIDS.

[11, 298; 21, 79). Another method employs alcoholic instead of an aqueous solution of io-urea (Baumann, B. 6, 1376; Prätorius, J. pr. [2], 131). It is noteworthy that pure thio-urea does not admit of complete desulphurisation. In this reaction, the presence of traces of such substance as CNSNH<sub>2</sub>, however, renders the action of the HgO perfectly easy (Traube, B. 18, 11).

**Properties.**—Cyanamide is a white crystalline compound [40°]. When melted, however, it may be cooled far below 40° without solidification taking place. This, however, is at once effected by contact with a pointed solid body. V. sol. in water, alcohol, and ether; sl. sol. CS<sub>2</sub>, CHCl<sub>3</sub>, and benzene. Heated above 40° it passes into the homologous *n*-di-cyanidamide (CN)<sub>2</sub>NH<sub>2</sub>, and at about 150° it solidifies with evolution of heat, forming *n*-tri-cyantriamide or melamine, together with other products (Drechsel, J. pr. [2] 13, 331). Cyanamide suffers this intramolecular condensation with great readiness. The change takes place at once when a solution containing ammonia is evaporated, or, again, when an alcoholic solution is heated together with phenol. In these cases the dicyanogen homologue results. More slowly cyanamide polymerises into dicyandiamide simply by standing.

**Reactions.**—1. CNNH<sub>2</sub> is reduced by nascent I (Zn and HCl), with the formation of NH<sub>3</sub> and FeNH<sub>4</sub>. (a) CNNH<sub>2</sub> + H<sub>2</sub> = CNH + NH<sub>3</sub>, (b) CNH + H<sub>2</sub> = MeNH<sub>2</sub> (Drechsel).—2. Heated with KNO<sub>3</sub> a violent reaction takes place with evolution of nitrogen and production of carbon dioxide and di-cyanidamide 4CNNH<sub>2</sub> + 4KNO<sub>3</sub> = 2K<sub>2</sub>CO<sub>3</sub> + H<sub>2</sub>O + 8N + (CN)<sub>2</sub>NH<sub>2</sub> (Drechsel).—3. The addition of HNO<sub>3</sub> to an ethereal solution causes it to combine with a molecule of water, forming urea, which, being insoluble in the ether, separates. Sulphuric, phosphoric, salicylic and lactic acids behave in a similar manner (Baumann, B. 6, 1373; Prätorius).—4. With haloid acids direct addition compounds are formed.—5. With H<sub>2</sub>S, or better with yellow ammonium sulphide, cyanamide combines to form thio-urea.—6. AgNO<sub>3</sub> reacts on CNNH<sub>2</sub>, forming AgCN and a yellow locculent pp. CNNAg<sub>2</sub>. 3CNNH<sub>2</sub> + 4AgNO<sub>3</sub> = CNNAg<sub>2</sub> + AgCN + AgNO<sub>3</sub> + CO<sub>2</sub> + 6N + 3H<sub>2</sub>O. With glycocoll CNNH<sub>2</sub> yields glycoeyanamide Strecker, *Handw. d. Chem.* [2] 3, 286), and with nethyl-glycocoll CH<sub>3</sub>(NHMe)COOH it forms creatine.—8. CNNH<sub>2</sub> dissolves in aldehyde, and after standing the mixture becomes resinous, and contains the compound (CN)<sub>3</sub>NC<sub>2</sub>H<sub>5</sub>, a triethylidene melamine (Knop, A. 131, 253).—9. Heated with oxalic ether formomelamine (CN)<sub>2</sub>(NH<sub>2</sub>)<sub>2</sub>NHCHO results.—10. At high temperatures it combines with NH<sub>3</sub>, forming guanidine hydrochloride C(NH)<sub>2</sub>NH<sub>2</sub>·HCl and with NH<sub>4</sub>OH forming oxyguanidine hydrochloride C(NH)<sub>2</sub>NH<sub>2</sub>·HCl. In the same manner, with (CN)SNH<sub>2</sub> guanidine thiocyanate C(NH)<sub>2</sub>NH<sub>2</sub>·HSCN is obtained.—11. CNNH<sub>2</sub> combines directly with CN, forming a yellow powder (Hofmann, J. 1861, 530).—12. With CNOK cyanamide combines to form monopotassium amidodicyanate (CN)<sub>2</sub>NH<sub>2</sub>·OK.—13. *Alloxanthin* reacts on cyanamide, forming is-uric acid (Mulder, B. 6, 1286).—14. With *guanidin* it combines to form diguanidin.

**Combinations.**—With haloid acids (Drechsel,

J. pr. [2] 11, 315; Mulder, B. 7, 1634). CNNH<sub>2</sub>·2HCl is produced as a crystalline pp. when anhydrous HCl is conducted into an ethereal solution of cyanamide. V. sol. water, sol. alcohol, insol. ether. If to the alcoholic solution of this compound HgO be added, and the clear solution evaporated, crystals of CNNH<sub>2</sub>·HgCl<sub>2</sub>·8aq are obtained. They are v. sol. water. The corresponding HBr compound exists, CNNH<sub>2</sub>·2HBr (D.).—With chloral. The two compounds combine directly to form chloral cyanamide, CCl<sub>3</sub>CHO·CNNH<sub>2</sub> (R. Schiff a. Fileti, B. 10, 426).

### METALLIC DERIVATIVES.

**Formation.**—*Monometallic salts.* Aqueous or alcoholic solutions of alkalis or earths or alkyl alkalis, act on cyanamide, giving monoderivatives NaOEt + CNNH<sub>2</sub> = CNNHNa + EtOH (Drechsel, J. pr. [2] 11, 307; 16, 205; 21, 81). *Di-metallic salts.*—1. By the action of heat on earthy and other metallic cyanates, Ca(CNO)<sub>2</sub> = CNNCa + CO<sub>2</sub> (Drechsel).—2. By heating pure Ba(CN)<sub>2</sub> in a current of N. Ba(CN)<sub>2</sub> + N = CNNBa + CN (Drechsel).—3. CNNK<sub>2</sub> is among the products of the heating of KCN or CNOK with NaHO.

2KCN + 4NaHO = CNNK<sub>2</sub> + Na<sub>2</sub>CO<sub>3</sub> + Na<sub>2</sub>O + H<sub>2</sub> (Drechsel).—4. By heating together NH<sub>4</sub>Na and CNO<sub>2</sub>Na.

CNO<sub>2</sub>Na + NH<sub>4</sub>Na = CNNNa<sub>2</sub> + H<sub>2</sub>O (Drechsel)

**Properties.**—*Sodium salt* CN.NHNa. Fine crystalline powder. V. e. sol. water, sol. alcohol, insol. ether. It absorbs oxygen and CO<sub>2</sub> with avidity. With CO<sub>2</sub> it forms a salt of cyanamidocarboxylic acid CO<sup>NH</sup>C<sup>ONa</sup>, an isomeride of cyanic acid. With ethyl chloroformate ClCOOEt sodium cyanamide combines to form cyanamidodicarboxylic ether CN.N(COOEt)<sub>2</sub>. Isocyanic and isothiocyanic ethers combine with CNNHNa with the production of amido-dicyanic derivatives CNNHNa + CONEt = CN.(NNa).CONHET. *Calcium salt* (CN.NH)<sub>2</sub>Ca. This may be prepared by acting on CNNH<sub>2</sub> with Ca(HO)<sub>2</sub>·Aq. From an aqueous solution crystals of the salt C<sub>2</sub>N(CaOH)<sub>2</sub>·6aq have been obtained (G. Meyer, J. pr. [2] 18, 425).

*Disodium salt* CN.NNa<sub>2</sub>. Heated with charcoal it gives NaCN. *Sodium potassium salt* CN.NKNa (Drechsel). *Calcium salt* CN.NCa. Decomposed by water with formation of monosalt (Drechsel; G. Meyer). *Mercuric salt* CN.NHg<sup>2</sup> (Engel, Bl. [2] 21, 273). *Lead salt* CN.NPb. Ammoniacal solution of CNNH<sub>2</sub> gives a lemon-yellow pp. of this compound with Pb(C<sub>2</sub>H<sub>3</sub>O)<sub>2</sub>. *Copper salt* CN.NCu (Engel). *Silver salt* CN.NAg<sub>2</sub>. An amorphous yellow pp. V. e. sol. HNO<sub>3</sub>, insol. dil. ammonia. Explodes quietly when heated (Drechsel; Beilstein A. Geuther, A. 108, 99).

### ALCOYL DERIVATIVES.

*Acetyl cyanamide* C<sub>2</sub>H<sub>3</sub>N<sub>2</sub>O is (CN).NHAc.

**Formation.**—1. By the action of acetyl chloride on cyanamide in ethereal solution (Drechsel, J. pr. [2] 11, 344).—2. Sodium acetyl cyanamide is formed by treatment of sodium cyanamide with acetic anhydride. This is converted into the silver salt from which the silver is removed by H<sub>2</sub>S (Mertens, J. pr. [2] 17, 7).

**Properties.**—A syrupy acid liquid. V. sol.

water, alcohol, ether, and chloroform, insol. benzene. When heated the liquid undergoes a violent reaction and is converted into a solid (polymeric?) mass (Mertens).

**Combinations with metals.**—**Sodium salt** (CN)NaCNa. A hygroscopic crystalline powder. Sol. alcohol, insol. ether. Heated it splits into acetonitrile and sodium cyanate. **Silver salt** (CN)NaCNaAg. Prepared by precipitating (CN)NaCNa, 4q with  $\text{AgNO}_3$ . A white crystalline powder. Insol. water, v. sol. ammonia. Heated it evolves acetonitrile.

**Diacetyl cyanamide**  $\text{C}_4\text{H}_5\text{N}_3\text{O}_2$  i.e. (CN)NaCNa. Rhombic plates decomposing at  $65^\circ$ . Insol. water, w. sl. sol. alcohol, sol. ether. Obtained by acting upon CNHAc in ethereal solution with  $\text{AcCl}$  (Mertens).

**Butyryl cyanamide**  $\text{C}_4\text{H}_7\text{N}_3\text{O}$  i.e. (CN)NH(C $_4\text{H}_7\text{O}$ ). The sodium salt is formed by acting on (CN)NHNa with (C $_4\text{H}_7\text{O}$ ) $_2\text{O}$  in ethereal solution. This salt is insol. ether, but sol. water. From the aqueous solution  $\text{AgNO}_3$  ppts. the silver salt, which is sol. ammonia, and from which the free cyanamide may be obtained.

**Isovaleryl cyanamide**  $\text{C}_5\text{H}_9\text{N}_3\text{O}$  i.e. (CN)NH(C $_5\text{H}_9\text{O}$ ). Formed in a similar way to acetyl-cyanamide. An acid syrup, sol. water, alcohol, and ether. Converted by heat, with a violent reaction, into a solid (polymeric?) mass. **Silver salt** (CN)N(C $_5\text{H}_9\text{O}$ )Ag.

**Benzoyl cyanamide**  $\text{C}_7\text{H}_5\text{N}_3\text{O}$  i.e. (CN)NHBz.

**Formation.**—By the action of benzoyl chloride BzCl on sodium cyanamide (CN)NHNa in ethereal solution.

**Properties.**—Unstable. Decomposes into  $\text{CO}_2$ , (CN)NH, and BzCN. Digested in ethereal solution it polymerises to tribenzoyl normal melamine (Gerlich, *J. pr.* [2] 13, 272).

**Lactocyanamide** v. LACTIC ACID.

**Succinocyanimic acid**

**Succinocyanimide** } v. SUCCINIC ACID.

**Succinocyanamide**

CARBOXYLIC DERIVATIVES.

**Cyanamidocarbonic acid** v. CYANAMIDOCARBOXYLIC ACID.

**Cyanamidodicarbonic acid** v. CYANAMIDODICARBOXYLIC ACID.

**Condensed cyanamido compounds.**

**Cyanogen cyanamide**  $\text{C}_2\text{HN}$ , i.e. (CN)NH(CN). Not known in a free state. CN.NK.CN is formed by the action of KHO on CNCl or paracyanogen, or by fusing paracyanogen with KCN. Needles. CN.NAg.CN is ppd. when  $\text{AgNO}_3$  is added to an aqueous solution of CN.NK.CN (Bannow, *B.* 4, 254).

**Isocyanic acid**  $\text{CHN}$  i.e. (C:O):NH. Isocyanic acid has not hitherto been isolated, neither are halogen or metallic derivatives known.

**ALKYL DERIVATIVES. Isocyanic ethers.**

**Formation.**—1. By distilling alkyl sulphate of potassium with potassium cyanate. Part of the isocyanic ether formed polymerises to isocyanurate (Wurtz, *A. Ch.* [3] 42, 43).—2. From carbamines by oxidation with  $\text{HgO}$  (Gautier, *A.* 149, 313).—3. By the action of alkyl iodides on silver cyanate (Brauner, *B.* 12, 1874).—4. By distilling alkyl-chloroformamides with lime (Gattermann, *A.* 244, 36).

**Properties.**—Low-boiling pungent irritating liquids.

**Reactions.**—(Wurtz.) 1. Polymerise gradually on standing into the corresponding isocyanuric ethers.—2. **Hydrolysis** when heated with dilute KHOaq. they break down into  $\text{CO}_2$  and amines  $\text{CONEt} + \text{H}_2\text{O} = \text{CO}_2 + \text{NH}_4\text{Et}$ . When treated with water alone the reaction does not go so far,  $\text{CO}_2$  and s-dialkyl urea being formed,  $2\text{CONEt} + \text{H}_2\text{O} = \text{CO}_2 + \text{CO}(\text{NEt})_2$ .—3. With alcohols they combine to form alkyl-carbamic ethers, thus:  $\text{CONEt} + \text{EtHO} = \text{NHEt.CO.OEt}$ .—4. **Organic acids** react giving acid amides and carbonic acid  $\text{CONEt} + \text{AcOH} = \text{CO}_2 + \text{AcNEt}$ .—5. Anhydrides yield tertiary amides and carbonic acid  $\text{CONEt} + \text{Ac}_2\text{O} = \text{CO}_2 + \text{Ac}_2\text{NEt}$ .—6.  $\text{NH}_3$  and prim. and sec. amines combine to form substituted ureas  $\text{CONEt} + \text{NHEt} = \text{NEt.CO.NHEt}$ .—7. The oxygen may be replaced by sulphur by treatment with  $\text{P}_2\text{S}_5$ , mustard oils or isothiocyanic ethers being formed.

**Methyl isocyanate**  $\text{C}_2\text{H}_5\text{NO}$  i.e.

(C:O):NMe. ( $37^\circ$ ) (Gattermann); ( $44^\circ$ ) (Wurtz; Gautier).

**Ethyl isocyanate**  $\text{C}_2\text{H}_5\text{NO}$  i.e. (C:O):NEt. ( $60^\circ$ ). S.G. 0.898 (Wurtz). The pure ether does not polymerise on standing, but the presence of NaOEt quickly transforms it into isocyanurate (Hofmann, *J.* 1861, 515; *A.* 103, 353; 115, 275). In the same manner NEt, with which it does not combine, determines its polymerisation (Hofmann, *J.* 1862, 335). **Hydrochloride**  $\text{CONEt.HCl}$  is formed by acting directly on the ether with HCl gas, or by distillation of  $\text{CO}(\text{NEt})_2\text{HCl}$  (Habich a. Linprich, *A.* 109, 107). Highly pungent irritating liquid ( $95^\circ$ ) (H. a. L.). ( $108^\circ$ – $112^\circ$ ) (Gal, *B.* 8, 435). Water decomposes it with violence into  $\text{NH}_4\text{EtHCl}$  and  $\text{CO}_2$ . **Hydrobromide**  $\text{CONEt.HBr}$  ( $118^\circ$ – $122^\circ$ ) (Gal).

**Isopropyl isocyanate**  $\text{C}_3\text{H}_7\text{NO}$  i.e. (C:O):N(C $_2\text{H}_5$ ). ( $67^\circ$ ) (Hofmann, *B.* 15, 756).

**Isobutyl isocyanate**  $\text{C}_4\text{H}_9\text{NO}$  i.e. (C:O):N(C $_2\text{H}_5$ ). ( $110^\circ$ ) (Brauner, *B.* 12, 1877).

**Tertiary butyl isocyanate**  $\text{C}_4\text{H}_9\text{NO}$  i.e. (C:O):N(CMe $_3$ ). The action of isobutyl chloride on silver cyanate gives small quantities of isobutyl isocyanate together with *tert*butyl isocyanate, a polymeric butyl isocyanate, isobutylene, cyanic, and cyanuric acids. The polymeric isobutyl isocyanate remains behind after *tert*butyl isocyanate is distilled off, and may be separated from the other products by solution in ether (Brauner, *B.* 12, 1874). Aromatic pungent liquid. ( $85.5^\circ$  cor.). S.G. 9 0.8676. Does not solidify at  $-25^\circ$ .

**Isoamyl isocyanate**  $\text{C}_5\text{H}_{11}\text{NO}$  i.e. (C:O):N(C $_4\text{H}_9$ ). ( $100^\circ$ ) (Wurtz, *J.* 1849, 428); ( $134^\circ$ – $135^\circ$ ) (Custer, *B.* 12, 1330). Insol. and lighter than water. Solution of  $\text{PEt}_3$  in ether polymerises it to isocyanurate (Custer).

**Heptyl isocyanate**  $\text{C}_7\text{H}_{15}\text{NO}$  i.e. (C:O):N(C $_6\text{H}_{13}$ ). (above  $100^\circ$ ) (Cahours a. Pelouze, *J.* 1863, 526).

**Allyl isocyanate**  $\text{C}_3\text{H}_5\text{NO}$  i.e. (C:O):N(C $_3\text{H}_5$ ). ( $82^\circ$ ) (Cahours a. Hofmann, *A.* 102, 297).

**Benzyl isocyanate** v. BENZYL CYANATE.

**Phenyl isocyanate**  $\text{C}_6\text{H}_5\text{NO}$  i.e.

(C:O):NPh (Hofmann, *A.* 74, 9 a. 38; *J.* 1858, 848; *B.* 8, 665; 18, 764).

**Formation.**—1. By the distillation of melan-oximide  $(\text{C:NH})\begin{smallmatrix} \text{NPhCO} \\ \diagdown \\ \text{NPhCO} \end{smallmatrix}$ —2. By distilling oxa-

nilide  $\text{C}_6\text{O}_2(\text{NHPH})_2$  with  $\text{P}_2\text{O}_5$ .—3. By the action of  $\text{P}_2\text{O}_5$  on di-phenyl-urea. —4. By distilling alkyl carbanilate  $\text{NHPH.CO.OEt}$  with  $\text{P}_2\text{O}_5$ .—5. By acting on melted  $\text{CO}(\text{NHPH})_2$  or  $\text{NH}_4\text{Ph.HCl}$  with  $\text{COCl}_2$  (Hentschel, B. 17, 1234).

**Properties.**—Highly pungent irritating liquid (166° at 769 mm.). S.G. 1.092 at 15°. V.D. 4.09 (calc. 4.13).

**Reactions.**—1. In presence of  $\text{PET}_2$  or  $\text{C}_2\text{H}_5\text{N}$  (Snape, C.J. 49, 254), it polymerises to diphenyl-isocyanate  $(\text{C}_6\text{O})_2(\text{NPh})_2$ .—2. Heated with certain dry salts,  $\text{CH}_3\text{COOK}$ ,  $\text{HCOOK}$ , or  $\text{Na}_2\text{CO}_3$ , it polymerises to isocyanurate. —3. It forms addition compounds with  $\text{Cl}$  and  $\text{Br}$ .—4. Water immediately converts it into carbonilide and  $\text{CO}_2$ , thus:  $2\text{CONPh} + \text{H}_2\text{O} = \text{CO}_2 + \text{CO}(\text{NHPH})_2$ .—5. Alcohols and phenols combine with phenylisocyanate to form alkyl phenylcarbamates

$\text{CONPh} + \text{EtHO} = \text{CO}\begin{smallmatrix} \text{NHPH} \\ \diagdown \\ \text{OEt} \end{smallmatrix}$  6. Ammonia

amines and amides form with it substituted ureas. —7. Aniline is produced when it is heated with zinc-dust. —8. Heated with  $\text{Ac}_2\text{O}$ ; acetanilide and  $\text{CO}_2$  are among the products. —9. In presence of  $\text{AlCl}_3$  it combines with  $\text{C}_6\text{H}_6$  and its homologues to form benzanilide, &c.  $\text{CONPh} + \text{PhH} = \text{BzNHPH}$  (Leuckart, B. 18, 875). In the same manner it combines with phenolic ethers (Leuckart & Schmidt, B. 18, 2338).

**Combinations.**— $\text{CONPh.Cl}$ : unstable crystals (Gumpert, J. pr. [2] 32, 294).— $\text{CONPh.Br}_2$  (G.).— $\text{CONPh.HCl}$ : crystalline [45°] (Hentschel, B. 18, 1178).

*p*-Bromophenyl isocyanate  $\text{CONC}_6\text{H}_4\text{Br}$ . [89°]. (226°). Sol. ether (Dennstedt, B. 13, 228).

*o*-Tolyl isocyanate  $\text{C}_6\text{H}_4\text{NO}$  i.e.  $(\text{C}_6\text{O})\text{N}(\text{C}_6\text{H}_3)$ .

**Formation.**—By acting on ethyltolylcarbamate  $\text{CO}\begin{smallmatrix} \text{NHC}_6\text{H}_4 \\ \diagdown \\ \text{OEt} \end{smallmatrix}$  with  $\text{P}_2\text{O}_5$  (Girard, B. 6, 445).

**Properties.**—Liquid. (186°). Powerful pungent odour. Polymerises into a solid modification by the action of  $\text{PET}_2$  (Neville & Winther, B. 12, 2324).

*p*-Tolyl isocyanate  $\text{C}_6\text{H}_4\text{NO}$  i.e.  $(\text{C}_6\text{O})\text{N}(\text{C}_6\text{H}_3)$ . Similar to *o*-ether. Formed also from *p*-toluidine and  $\text{COCl}_2$  (Kühn & Henschel, B. 21, 506). (185°). Water decomposes it into di-*p*-tolyl-urea and  $\text{CO}_2$  (Hofmann, B. 3, 656).

Mesityl isocyanate  $\text{C}_6\text{H}_3\text{NO}$  i.e.  $(\text{C}_6\text{O})\text{N}(\text{C}_6\text{H}_2)$ . Disagreeable smelling liquid. (218°–220°) (Eisenberg, B. 15, 1017).

Cumyl isocyanate  $\text{C}_7\text{H}_7\text{NO}$  i.e.  $(\text{C}_6\text{O})\text{N}(\text{C}_6\text{H}_5)$  (Raab, B. 8, 1151).

(*a*)-Naphthyl isocyanate  $\text{C}_{10}\text{H}_7\text{NO}$  i.e.  $(\text{C}_6\text{O})\text{N}(\text{C}_{10}\text{H}_7)$ . Pungent irritating liquid. (269°–270°) (Hofmann, B. 3, 658).

Diphenyl isocyanate  $\text{C}_{12}\text{H}_9\text{NO}$   $(\text{C}_6\text{O})\text{N}(\text{C}_6\text{H}_5)_2$  (Zimmermann, B. 13, 1965).

Diphenylene diisocyanate  $\text{CO:N.C}_6\text{H}_4\text{.C}_6\text{H}_4\text{:N.CO}$  [122°] (Snape, C. J. 49, 255).

Thioisocyanic acid derivatives v. THIOISOCYANIC ACID.

**Isocyanamide**  $(\text{C:NH})\text{:NH}$ . This compound has not been isolated, but its alkyl derivatives exist.

#### ALKYL DERIVATIVES.

**Formation.**—1. By the action of  $\text{CNCl}$  on primary amines (Cloëz & Cannizzaro, A. 90, 95). 2. By the desulphurisation of alkyl thio-ureas  $\text{NH}_2\text{CS.NHMe} - \text{H}_2\text{S} = (\text{CNMe})\text{NH}$ .

**Properties.**—Neutral syrupy liquids. By repeated evaporation of their aqueous solutions, polymerisation to the corresponding isomelamines takes place (Baumann, B. 6, 1372; Klason, Bihang till K. Svenska Vet. Akad. Hand. 1885, [10] No. 7).

Methylisocyanamide  $\text{C}_2\text{H}_5\text{N}_2$  i.e.  $(\text{CNMe})\text{:NH}$  (Baumann, B. 6, 1372).

Diethylisocyanamide  $\text{C}_4\text{H}_{10}\text{N}_2$  i.e.  $(\text{CNEt})\text{:NH}$ .

**Formation.**—1.  $(\text{CNEt})\text{NH}$  breaks down when distilled into  $(\text{CNEt})\text{NET}$  and a crystalline base, possibly ethyldicyandiamide (Cloëz & Cannizzaro). —2. By the action of  $(\text{CN})\text{NAg}$  on  $\text{EtI}$  (R. Schiff & Fileti, B. 10, 428).

**Properties.**—Liquid. (186°) (S. a. F.); (190°) (C. a. G.). By treatment with  $\text{HCl}$  it yields  $\text{CO}_2$ ,  $\text{NH}_3$ , and  $\text{NHEt}_2$ .

Allylisocyanamide  $\text{C}_3\text{H}_5\text{N}_2$  i.e.  $(\text{CNCH}_2\text{CH}_2)\text{:NH}$ .

**Formation.**—(Will, A. 52, 15; Robiquet & Bussy, J. pr. 19, 234; Andreasch, M. 2, 780).

**Properties.**—A thick syrupy liquid which gradually crystallises in monoclinic four-sided prisms with  $\frac{1}{2}\text{H}_2\text{O}$ . [100°]. Sol. water, alcohol, and ether. Strong alkaline reaction. Precipitates metallic oxides from solution of their salts and liberates ammonia from its combination with acids. The oxalate is difficultly crystallisable. Its solution gives precipitates with  $\text{HgCl}_2$  and  $\text{PtCl}_4$ :— $\text{C:NCH}_2\text{CH}_2\text{:NH.HgCl}_2$  and  $(\text{C:NCH}_2\text{CH}_2\text{:NH})_2\text{PtCl}_4$ .

Allyloethylisocyanamide  $\text{C}_5\text{H}_9\text{N}_2$  i.e.  $(\text{CNEt})\text{:NCH}_2\text{CH}_2$ .

**Properties.**—Needles. [100°]. Insol. water, sol. alcohol and ether. Reaction alkaline. Taste bitter. Compounds with  $\text{HgCl}_2$  and  $\text{PtCl}_4$ :— $(\text{CNEt:NCH}_2\text{CH}_2)_2\text{HgCl}_2$  and  $(\text{CNEt:NCH}_2\text{CH}_2)_4\text{PtCl}_4$  (Hinterberger, A. 83, 346).

Benzylisocyanamide v. BENZYLISOCYANAMIDE.

Dibenzylisocyanamide v. DIBENZYLISOCYANAMIDE.

Phenylisocyanamide  $\text{C}_7\text{H}_7\text{N}_2$  i.e.  $(\text{CNPh})\text{:NH}$ .

**Formation.**—(Cloëz & Cannizzaro; Hofmann, B. 3, 266; 18, 3220; Berger, M. 5, 219 a. 453; Rathke, B. 12, 773).

**Properties.**—Syrup gradually crystallising in presence of alcohol in needles (Feuerlein, B. 12, 1602). [47°] (Hofmann). V. sl. sol. water; sol. alcohol and ether. When water is added to the alcoholic solution phenyl-urea,  $\text{CO.NHPH.NH}_2$ , is precipitated. In the same manner in a benzene solution  $\text{H}_2\text{S}$  gives phenyl-thio-urea (Weith, B. 9, 820). Silver salt:  $\text{C:NPh:NAg}$  (Hofmann; Feuerlein; Berlinerblau, J. pr. [2] 30, 114). Platinum chloride salts:  $(\text{C}_7\text{H}_7\text{N}_2\text{HCl})_2\text{PtCl}_4$  (Feuerlein);  $(\text{C}_7\text{H}_7\text{N}_2\text{HCl})_2\text{PtCl}_4$  (Hofmann). With acetamide, among other products, two bases,  $\text{C}_{10}\text{H}_9\text{N}_3$  and  $\text{C}_{12}\text{H}_9\text{N}_3$ , are formed (Berger).

Diphenylisocyanamide  $\text{C}_{12}\text{H}_9\text{N}_2$  i.e.  $(\text{CNPh})\text{:NPh}$ . Formed by the action of  $\text{CNCl}$

on diphenylamine (Weith, *B.* 7, 848). Rhombohedra. [292°]. Heated with conc. HCl it gives  $\text{NH}_3$ ,  $\text{NHPh}$ , and  $\text{CO}$ .

DICYANOGEN GROUP.

**Fulminic acid**  $\text{C}_2\text{H}_2\text{N}_2\text{O}_2$ . This dibasic acid has not been isolated. A solution in ether is, however, probably obtained when dry HCl is conducted into a mixture of fulminating mercury with that solvent. It forms acid neutral and double salts, all of which are explosive compounds. The mercury and silver compounds have long been known and employed for the filling of percussion caps. The ethereal solution treated with NaHO evolves  $\text{NH}_3$ , but no amine. When it is shaken with  $\text{NH}_3$ , isofulminuric acid, fulminuramide, and other products are formed (Ehrenberg, *J. pr.* [2] 30, 55). Dilute  $\text{H}_2\text{SO}_4$  also sets free fulminic acid in presence of ether, but in this case the products of its decomposition give rise to another series of isomeric modifications (Scholvién, *J. pr.* [2] 32, 481). Only metallic derivatives of fulminic acid are known.

METALLIC DERIVATIVES.

**Disodium fulminate**  $\text{Na}_2\text{C}_2\text{N}_2\text{O}_2$  2aq. Formed from mercuric fulminate suspended in water by the action of sodium amalgam. The liquid concentrated over  $\text{H}_2\text{SO}_4$  or CaO deposits prismatic crystals of the disodium salt. Explodes when rubbed or heated.  $\text{H}_2\text{O}$  decomposes it with formation of  $\text{NH}_3$ ,  $\text{CO}_2$ , and HCN (Ehrenberg, *J. pr.* [2] 32, 231).

**Disilver fulminate**  $\text{Ag}_2\text{C}_2\text{N}_2\text{O}_2$ .

**Preparation.**—1 pt. of silver is dissolved in 10 pts. of  $\text{HNO}_3$  (S.G. 1.36), and the solution poured into 20 pts. of spirits of wine (85–90 p.c.) (Brugnattelli, *A. Ch.* 1798, 27, 331; Gerhardt, *Traité de Chim. Org.* 2, 348). The salt separates in fine needles.

**Properties.**—S. 36 at 100° (Liebig, *B. J.* 4, 111); v. sl. sol. cold water; v. sol. ammonia. More explosive than the mercury salt.

**Reactions.**—1. Half of the metal is replaced by treatment with *alkaline chlorides* (Gay-Lussac & Liebig, *A. Ch.* [2] 25, 285).—2. *Hydrochloric acid* separates all the silver, but with breaking up of the molecule of the acid (Gay-L. & L.). When fuming HCl is employed three-quarters of the molecule breaks down into hydroxylamine and formic acid, the other products being  $\text{CO}_2$ ,  $\text{NH}_3$ , and HCN. With dilute acid more  $\text{NH}_3$  and formic acid are formed, and only traces of  $\text{NH}_3$  (Divers & Kawakita, *C. J.* 45, 16; 47, 69).

**Silver sodium fulminate**  $\text{NaAgC}_2\text{N}_2\text{O}_2$ . Small crystalline plates.

**Silver potassium fulminate**  $\text{KAgC}_2\text{N}_2\text{O}_2$ . Colourless plates. S. 8 at 100° (Liebig).

**Silver hydrogen fulminate**  $\text{HAgC}_2\text{N}_2\text{O}_2$ . Falls as a pulverulent pp. when conc.  $\text{HNO}_3$  is added to an aqueous solution of  $\text{AgK}_2\text{C}_2\text{N}_2\text{O}_2$  (Liebig).

**Zinc fulminate**  $\text{ZnC}_2\text{N}_2\text{O}_2$  (E. Davy, *B. J.* 12, 120).

**Zinc hydrogen fulminate**  $\text{ZnH}_2\text{C}_2\text{N}_2\text{O}_2$  (E. Davy; Fehling, *A.* 27, 130).

**Copper fulminate**  $\text{CuC}_2\text{N}_2\text{O}_2$  (Gladstone, *A.* 66, 1).

**Mercuric fulminate**  $\text{Hg}^{\text{C}}\text{C}_2\text{N}_2\text{O}_2$ .

**Preparation.**—8 pts. of mercury are dissolved in 36 pts. of  $\text{HNO}_3$  (S.G. 1.845) in a large

flask without the application of heat. The solution is poured into 17 pts. of spirits of wine (90–92 p.c.) and the mixture returned to the large flask. After a time a violent reaction commences, which is moderated by the addition of more spirits of wine to the extent of another 17 pts. Mercuric fulminate gradually deposits, and is collected and recrystallised from water. It may be also purified by solution in KCN and reprecipitation by means of dilute acids (Howard, *Tr.* 1800; Liebig, *A.* 95, 284; Steiner, *B.* 9, 787).

**Properties.**—Mercuric fulminate crystallises from alcohol in minute octahedra, from water in needles containing  $\frac{1}{2}\text{aq}$  (Schischkow, *A.* 97, 54). S.G. (anhydrous) 4.12 (Berthelot & a. Vieille, *A. Ch.* [5] 21, 569). V. sl. sol. cold, more sol. hot water. Explodes by heat, friction or percussion, or by treatment with  $\text{H}_2\text{SO}_4$ . The products of decomposition are  $\text{Hg}$ ,  $\text{N}_2$ , and  $\text{CO}$ . H.C. (Berthelot & a. Vieille).

**Reactions.**—1.  $\text{Zn}$  and  $\text{H}_2\text{SO}_4$ , or  $\text{Sn}$  and HCl, or zinc dust and ammonia, break down the molecule into  $\text{Hg}$ ,  $\text{CO}_2$ , and  $\text{NH}_3$ .—2. *Sodium amalgam* converts it into the Na salt. The by-products of this reaction, by treatment with ferrous and ferric oxides yield among other compounds nitroprussides.—3. Heated with water containing Cu or Zn, these metals displace the mercury.—4. *Chlorine* conducted into the salt mixed with water reacts, forming  $\text{HgCl}_2$ ,  $\text{CNCl}$ , and chloropierin  $\text{C}(\text{NO})\text{Cl}$  (Kekulé, *A.* 101, 206).—5. *Bromine* in the same manner forms dibromonitroacetoneitril  $\text{CBr}_2\text{NO}_2\text{CN}$  (Schischkow).—6. Heated for 8 hours with water alone, or for a shorter time in presence of NaCl or  $\text{NH}_4\text{Cl}$ , it polymerises to the corresponding fulminurate (Schischkow; Liebig).—7. Mixed with ether it reacts with dry  $\text{H}_2\text{S}$  forming  $\text{HgS}$ , nitrothioacetamide  $\text{CH}_3(\text{NO}_2)\text{CSNH}_2$ , oxalic acid and ammonium thiocyanate. In presence of water the products are  $\text{HgS}$ , ammonium thiocyanate, and  $\text{CO}_2$  (Kekulé).—8. Mixed with  $\text{KHOAc}$  and heated, a pp. of  $\text{HgO}$  falls.—9. *Ammonia* dissolves mercuric fulminate, but when the solution is heated to 60°–70° a reaction takes place with the production of urea, guanidin, and the compound called fulmitriganarate. Heated in closed tubes to 70° with alcoholic ammonia the compound fulmitetraguanarate is also formed (Steiner, *B.* 8, 520, 1177; 9, 781).—10. Conc. HCl or HBr react, evolving  $\text{CO}_2$ , precipitating  $\text{HgCl}$  and 2 mol. of  $\text{NH}_4\text{OH}$  going into solution. Traces of HCN also occur, but no  $\text{NH}_3$  (Steiner, *B.* 16, 1484 & 2119; Carstanjen & Ehrenberg, *J. pr.* [2] 25, 232).—11. Dilute HCl in the cold yields formic acid, hydroxylamine and  $\text{HgCl}_2$  (Ehrenberg, *J. pr.* [2] 30, 41).—12.  $\text{H}_2\text{SO}_4$  (1 in 5) reacts on warming, forming  $\text{CO}_2$ ,  $\text{NH}_3$ ,  $\text{NH}_4\text{OH}$ ,  $\text{HgSO}_4$ , and  $\text{Hg}_2\text{C}_2\text{O}_4$  (?) (Ehrenberg & Carstanjen; Divers & Kawakita).—13. Conc. HCN dissolves the fulminate, but when the solution is diluted  $\text{Hg}(\text{CN})_2$  precipitates.—14. Aqueous  $\text{CSNH}_2$  reacts, forming  $\text{CO}_2$ ,  $\text{Hg}(\text{SCN})_2$ , and  $\text{NH}_4\text{SCN}$ . With  $\text{NH}_4\text{SCN}$  polymerisation to fulminurate takes place (Ehrenberg, *J. pr.* [2] 30, 62).

**Combinations.**—With KI:  $(\text{HgC}_2\text{N}_2\text{O}_2)_2\text{KI}$  (Schischkow).—With KCN:  $\text{HgC}_2\text{N}_2\text{O}_2\cdot\text{KCN}$  (Steiner, *B.* 9, 786).—With KSCN it forms  $\text{HgC}_2\text{N}_2\text{O}_2\cdot\text{KSCN}$  (Schischkow).—With  $\text{Na}_2\text{C}_2\text{N}_2\text{O}_2$ ,  $\text{HgC}_2\text{N}_2\text{O}_2\cdot\text{Na}_2\text{C}_2\text{N}_2\text{O}_2$  aq (Ehrenberg).

**Compound  $C_2H_2HgN_2O_4$ .**

**Formation.**—This substance, the nature of which is little known, is formed when a cold solution of  $Hg(NO_3)_2$  free from fumes of  $HNO_3$  is thrown into alcohol (Cowper, *C. J.* 39, 242).

**Properties.**—Minute hexagonal plates. Decomposes quickly when gently heated, but if the temperature is suddenly raised to about  $130^\circ$  it explodes. Insol. water, alcohol, and ether. Sol.  $HCl$  with decomposition. Sol. and may be recrystallised from dilute  $H_2SO_4$ .

**Reactions.**—1. With  $H_2SAg$  the compound yields  $HgS$  and mercaptan. — 2. Digested with caustic alkalis nitric acid is removed, and the compound  $C_2H_2(HgO)_2 \cdot H_2O$  remains. — 3. Heated with alcohol and  $HNO_3$  it is converted into mercuric fulminate.

**Normal amidodicyanic acid  $C_2H_2N_2O_4$  i.e.  $(HO)C \begin{smallmatrix} \diagup N \\ \diagdown N \end{smallmatrix} C(NH_2)$ . Semi-amide of normal dicyanic acid.**

**Formation.**—1. By heating dicyandiamide with baryta water one of the amido-groups is replaced by hydroxyl (Hallwachs, *A.* 153, 295). 2. By allowing a solution of  $CNOK$  to stand together with cyanamide, when direct combination takes place,  $NH_2(CN)_2OK$  being formed (Hallwachs).

**Properties.**—Needles. Monobasic acid. Decomposes carbonates. Heated alone or together with dilute  $H_2SO_4$ , it takes up the elements of water, forming biuret, thus:  $(CN)_2(NH_2)OH + H_2O = NH_2.CO.NH.CO.NH_2$ . In the same manner with  $(NH_4)_2S$  thiobiuret is obtained (Baumann, *B.* 8, 709).

**METALLIC DERIVATIVES.**

$(CN)_2NH_2OK$ . —  $NaA'$ . —  $BaA'$ , 3aq. —  $CuA'$ , 4aq. Large blue crystals. V. sl. sol. cold water. Aqueous solution, when boiled, deposits a dark green pp. insol. water, and v. sl. sol. cold acetic acid. This pp. has the composition  $C_2N_2CuHO$  i.e.  $(?) (CN)_2 \begin{smallmatrix} \diagup NH \\ \diagdown O \end{smallmatrix} Cu$ . —  $(CN)_2(NH_2)OAg$ . Amorphous powder, or from ammoniacal solution in needles. Insol. water.

**ALKYL DERIVATIVES.**

**Ethyl amidodicyanate  $C_2H_2N_2O_4$  i.e.  $? NH_2C \begin{smallmatrix} \diagup N \\ \diagdown N \end{smallmatrix} C(NH_2) \cdot CO$ .** The sodium salt of this compound is formed by direct combination of ethyl isocyanate and normal sodium cyanamide. The free acid decomposes when liberated with formation of cyanamide and other products.

**Salts.**— $(CNCO):NEt.NHNa$ . —  $AgA'$  (Wunderlich, *B.* 19, 449).

**Dithiodicyanic acid v. DITHIODICYANIC ACID.**

**Normal dicyandiamide  $C_2H_2N_4$  i.e.**

$(NH_2)C \begin{smallmatrix} \diagup N \\ \diagdown N \end{smallmatrix} C(NH_2)$ . **Di-amide of normal dicyanic acid.**

**Formation.**—Cyanamide polymerises to dicyandiamide by long continued evaporation of its aqueous solution (Beilstein & Geuther, *A.* 108, 99; 123, 241). This change is more readily effected if a little  $NH_3$  is present (Haag, *A.* 122, 22), or dilute alkalis, or even in the cold when concentrated alkalis are employed (Baumann, *B.* 6, 1373).

**Properties.**—Broad laminae [ $205^\circ$ ] (Haag). Sol. water and alcohol. Insol. ether (cyanamide is sol. ether).

**Reactions.**—1. Heated alone one part polymerises to normal melamine, another loses  $NH_3$  and forms melam (Drechsel, *J. pr.* [2] 13, 331). — 2. Heated with water polymerisation takes place, and at the same time two amidegen groups are replaced by hydroxyl, forming melanuric acid  $(CN)_2(NH_2)(OH)$ , and  $NH_3$ . This acid is also formed by heating dicyandiamide to  $120^\circ$  with a solution of  $(NH_4)_2CO_3$ . — 3. Heated with dilute acids it assumes the elements of water, forming guanylurea  $CO \begin{smallmatrix} \diagup NH \\ \diagdown C(NH)NH_2 \end{smallmatrix}$ . Similarly with  $H_2S$  guanylthiourea is produced. — 4. With  $HCl$  and zinc melamine and  $NH_3$  are formed (*cf.* Bamberger, *B.* 16, 1462). — 5. Guanidin hydrochloride, together with  $CO$  and  $NH_3$ , are formed by heating it with  $NH_4Cl$  at  $150^\circ$  (Rathke, *B.* 18, 3107). 6. Heating with  $Ba(OH)_2 \cdot 8H_2O$  one amido group is replaced by hydroxyl, leaving amidodicyanic acid. — 7. It combines with  $CNSH$  to form thioammeline  $(CN) \begin{smallmatrix} \diagup NH_2 \\ \diagdown SH \end{smallmatrix} (Rathke, B. 18, 3102)$ .

**METALLIC DERIVATIVES.**

**Sodium dicyandiamide  $C_2H_2N_4Na$  i.e.  $(CN)_2(NH_2)NHNa$ .** A soluble crystalline pp. obtained by mixing together alcoholic solutions of dicyandiamide and sodium ethylate (Bamberger, *B.* 16, 1461).

**Dicyandiamido silver nitrate  $(C_2H_2N_4)AgNO_3$ .** Precipitated in minute needles on adding  $AgNO_3$  to an aqueous solution of dicyandiamide (Haag).

**Silver dicyandiamide  $C_2H_2N_4Ag$  i.e.  $(CN)_2(NH_2)NHAg$ .** Formed by treating an aqueous solution of dicyandiamido silver nitrate with ammonia.

**ALKYL DERIVATIVES.**

**Ethyl dicyandiamide  $C_2H_2N_4$  i.e.  $(CN)_2(NH_2)NHEt$ .** A weak base formed by distilling ethyl cyanamide (Clôez & Cannizzaro, *A.* 90, 96). Distils unchanged at  $300^\circ$ . Gives a yellow insoluble platinumchloride salt.

**ALKOYL DERIVATIVES.**

**Dibenzoyl dicyandiamide  $C_{10}H_{12}N_4O_2$  i.e.  $(CN)_2(NHCBz)_2$ .** Formed by heating tribenzoylmelamine in a current of hydrogen. Crystals. [ $112^\circ$ ]. V. sol. alcohol, less sol. ether, v. sl. sol. water (Gerlich, *J. pr.* [2] 13, 272).

**Isodicyanic acid  $C_2H_2N_2O_4$  i.e.  $(C:O)_2(NH)_2$  or  $CO \begin{smallmatrix} \diagup NH \\ \diagdown NH \end{smallmatrix} CO$ .** Alkyl derivatives corresponding to this hypothetical acid have been prepared.

**ALKYL DERIVATIVES.**

**(?) Dimethyl isodicyanate  $C_2H_2N_2O_4$  i.e.  $CO \begin{smallmatrix} \diagup NMe \\ \diagdown NMe \end{smallmatrix} CO$ .** Methyl isocyanate polymerises in presence of  $PEt$ , to a solid compound [ $98^\circ$ ] (Hofmann, *B.* 3, 765), which is not identical with either methyl isocyanurate [ $175^\circ-6^\circ$ ] or methyl cyanurate [ $135^\circ$ ], and which possibly has the above constitution.

**Diphenyl isodicyanate  $C_{10}H_8N_2O_4$  i.e.  $CO \begin{smallmatrix} \diagup NPh \\ \diagdown NPh \end{smallmatrix} CO$ .**

**Formation.**—By polymerisation of phenyl isocyanate in presence of  $PEt$ , (Hofmann, *A. Suppl.* 1, 57; *B.* 4, 246) or pyridine (Snape, *C. J.* 49, 254).

**Properties.**—Square tables from alcohol [ $175^\circ$ ]. Insol. water or ether, v. sl. sol. alcohol.

**Reactions.**—1. Heated it evolves phenyl isocyanate.—2. Heated with alcohols it forms alkyl diphenylallophanates  $\text{CO.NHPh.NPhCOOEt}$ .—3. With phenol phenyl-carbanilate is formed  $\text{NHPh.CO.OPh}$ .—4. Alcoholic ammonia reacts with the formation of  $\beta$ -di-phenyl-biuret  $\text{NHPh.CO.NPh.CO.NH}_2$ .—5. With aniline tri-phenyl-biuret results.

**Derivative.**—Di-*p*-bromo-phenyl isodicyanate  $(\text{CO})_2(\text{NC}_6\text{H}_4\text{Br})_2$  is formed by polymerisation of *p*-bromo-phenyl isocyanate with  $\text{PbEt}_2$ . Laminar. [199°] (Dennstedt, B. 13, 228).

**Di-*p*-tolyl dicyanate**  $\text{C}_{12}\text{H}_8\text{O}_2(\text{C}_6\text{H}_4)_2$ . [185°] (Frentzel, B. 21, 411). Converted by alcohol into di-*p*-tolyl allophanic ether [111°].

#### TRICYANOGEN GROUP.

Normal cyanuric acid  $\text{C}_3\text{H}_3\text{N}_3\text{O}_3$ , i.e.

**Formation.**—1. Dry distillation of uric acid (Scheele, *Opuscula*, 2, 76).—2. By the action of water on  $(\text{CN})_2\text{Cl}_2$  (Serullas, A. Ch. 38, 390).—3. By the action of heat on urea (Wöhler, L. 15, 622). Instead of urea itself the salts of urea may be employed (Pelouze, A. 44, 106; De Vrij, A. 61, 219; Wiedemann, A. 68, 324).—4. By heating cyamelide with conc.  $\text{H}_2\text{SO}_4$  (Weltzien, A. 132, 222).—5. Cyanuric acid is one of the products of the action of  $\text{COCl}_2$  on  $\text{NH}_3$ .—6. The action of heat on xanthogenamide  $3\text{CS}(\text{NH}_2)\text{OEt} = (\text{CN})_2(\text{OH}) + 2\text{HHS}$  (Debus, A. 72, 1).—7. By the action of  $\text{HCl}$  on such compounds as melian, melien, melon, melonic hydride, melamine, ammelime, ammelide, pseudothiocyanogen, and thiopruessides.—8. From guanamide by oxidation with  $\text{HNO}_3$  (Nencki, B. 9, 235).—9. From cyanic acid by spontaneous polymerisation together with cyamelide. This may be effected by adding  $\text{HCl}$  to  $\text{CNOKa}$  in presence of ether and agitating. The cyanuric acid is taken up by the ether (Klason, J. pr. [2] 33, 129).

**Preparation.**—1. Urea is heated till it ceases to give off ammonia, the residue is dissolved in boiling water, and the filtrate left to crystallise on cooling. The crystals so obtained are purified by dissolving them in hot  $\text{H}_2\text{SO}_4$  and dropping in  $\text{HNO}_3$  until the solution is colourless and effervescence has ceased. After cooling the solution is diluted with water when the cyanuric acid falls as a snow-white powder (Wöhler & Liebig).—2. Dry chlorine gas is passed into molting urea, whereupon the mass swells up strongly, gives off fumes of  $\text{NH}_4\text{Cl}$ , together with  $\text{HCl}$  and  $\text{N}$ , and is converted into cyanuric acid (Wurtz, A. 64, 307).—3. De Vrij (A. 61, 248) uses  $\text{HCl}$  instead of  $\text{Cl}_2$ . Serullas prepares the acid from cyanuric chloride, and Merz & Weith (B. 16, 2896) similarly employ cyanuric bromide.

**Properties.**—Colourless oblique rhombic prisms (from water) containing 2aq, or anhydrous octahedra. Measurements (Weferstein & Schabus, P. 99, 276). Crystals effloresce. By heating to  $100^\circ$ – $120^\circ$ , or by crystallisation from conc.  $\text{HCl}$  or  $\text{H}_2\text{SO}_4$ , the acid becomes anhydrous (Wöhler, B. 7, 10, 83; Voit, A. 132, 222). S.G.  $^{\circ} 1.768$ ;  $^{\circ} 2.600$ ;  $^{\circ} 2.223$ ;  $^{\circ} 1.725$  (Troost & Haut-

feuille, J. 1869, 90; cf. Schröder, B. 13, 1072). H.C. 250,260 (T. & H.). S. 2.5 cold, more sol. hot water. S. (alcohol)  $21^\circ$ – $24^\circ$ , 0.1 (Senier, C. J. 49, 695). Sol. hot  $\text{HCl}$ ,  $\text{HNO}_3$ , or  $\text{H}_2\text{SO}_4$ , without decomposition unless the heat be prolonged for a considerable time. Absorption spectrum (Hartley, C. J. 41, 48). By treatment with  $\text{PCl}_5$  cyanuric chloride is formed (Beilstein, A. 116, 357).

**Test Reactions.**—1. Heated in a small tube closed at one end it evolves cyanic acid, the pungent odour of which may be detected even in the case of very minute quantities (Wöhler).—2. A fragment of the acid is dissolved in dilute ammonia and a drop of ammonio-sulphate of copper solution added. On stirring a beautiful pink copper salt is precipitated (Wöhler).—3. A saturated solution of the acid in cold conc.  $\text{NaHOaq}$  becomes thick with suspended crystals of the tri-sodium salt on heating (Hofmann, B. 3, 770).

#### HALOGEN DERIVATIVES.

**Cyanuric chloride**  $\text{C}_3\text{N}_3\text{Cl}_3$ , i.e.  $(\text{CN})_2 \begin{array}{c} \text{Cl} \\ \diagdown \quad \diagup \\ \text{Cl} \end{array}$

**Formation.**—1. By the action of anhydrous  $\text{Cl}_2$  on anhydrous  $\text{HCN}$  in presence of sunlight (Serullas, A. Ch. [2] 35, 291 a. 337; Liebig, P. 20, 369; 34, 604).—2. By treatment of cyanuric acid with  $\text{PCl}_5$  (Beilstein, A. 116, 357).

**Preparation.**—The employment of the method of Serullas has given rise to several improvements, chiefly with the view of preventing the formation of persistent double compounds of  $\text{HCl}$  and  $\text{HCN}$ . The  $\text{HCN}$  is dissolved in anhydrous ether, into which the  $\text{Cl}_2$  is led (Gautier, A. 141, 122), or the ether may be advantageously replaced by chloroform, in which  $\text{Cl}_2$  is more soluble, for an excess of this agent leads to a better result. 70 p.c. of the theoretical yield was thus obtained by Klason (*Bihang till K. Svenska Vet. Akad. Handl.* 1885, 10, No. 5). Another plan to attain this end is to ensure excess of  $\text{Cl}_2$  from the commencement. The chloroform surrounded by a freezing mixture is first saturated with chlorine, and then a mixture of  $\text{Cl}_2$  and  $\text{HCN}$  is passed slowly in until after some 24 hours the evolution of  $\text{HCl}$  ceases, and the whole of the  $\text{HCN}$  is converted into chloride. A portion of the cyanuric chloride in most instances separates from the  $\text{CHCl}_3$  during the operation in beautiful crystals. The remainder is obtained by distilling off the chloroform (Fries, C. J. 49, 739).

**Properties.**—Colourless crystals. Measurements (Hofmann (Fock), B. 19, 2053). [146°] (Hofmann). [190°] (Serullas). V.D. 6.35 (calc. 6.39) (Bineau, A. Ch. [2] 68, 424). Odour resembling mice. Exceedingly irritating to the eyes. Very poisonous.

**Reactions.**—1. Cold water has little or no action on  $(\text{CN})_2\text{Cl}_2$ . By long boiling with water or quickly in presence of alkalis it is converted into cyanuric acid (Serullas).—2. Alcohols and phenol behave similarly to water, cyanuric acid and alkyl chlorides being formed (Klason).—3.  $\text{KHS}$  in the same manner gives trithiocyanuric acid (Hofmann, B. 18, 2201).—4. Ammonia or amines react successively, forming normal mono- and di-amide-chlorides, and finally normal melamines (Hofmann, D. 18, 2774; Klason, J. pr. [2] 38, 294).—5. Cyanuric chloride reacts on the

anhydrous sodium salts of organic acids giving acid chlorides and sodium cyanurate (Senier, *C. J.* 49, 312).—6. *Benzamide* is converted by cyanuric chloride into benzonitrile, and the water thus liberated acts on the chloride forming cyanuric acid and HCl (Senier).

**Cyanuric bromide**  $C_3N_3Br_3$ , i.e.  $(CN)_3$   $\begin{smallmatrix} \nearrow Br \\ \nearrow Br \\ \nearrow Br \end{smallmatrix}$

**Formation.**—1. By the action of bromine on anhydrous HCN (Serullas, *P.* 14, 446; Ponomareff, *B.* 18, 3261; Merz a. Weith, *B.* 16, 2894).—2. By heating an ethereal solution of CNBr to 130°–140° (Eghis, *B.* 2, 159). Pure CNBr does not polymerise. Polymerisation may, however, be effected by passing HBr through an ethereal solution of CNBr when the less soluble polymeride comes out in crystals (Ponomareff).

**Properties.**—Amorphous white powder. At 300° it melts with decomposition. Insol. cold water, cold alcohol, ether, and benzene. Heated with water or alcohol it is converted into cyanuric acid. With acetic acid it yields cyanuric acid and acetyl bromide (Ponomareff).

**Cyanuric iodide**  $C_3N_3I_3$ , i.e.  $(CN)_3$   $\begin{smallmatrix} \nearrow I \\ \nearrow I \\ \nearrow I \end{smallmatrix}$

tained by double decomposition between  $(CN)_3Cl_3$  and HI in the cold (Klason, *Bihang till K. Svenska Vet. Akad. Handl.* 1885, 10, No. 5). A dark brown insoluble powder which at 200° decomposes into paracyanogen and iodine. Heated with water at 125° it splits into HI and cyanuric acid.

**Cyanuric chloro iodide**  $C_3N_3I_2Cl$ , i.e.  $(CN)_3$   $\begin{smallmatrix} \nearrow I \\ \nearrow Cl \\ \nearrow I \end{smallmatrix}$  An intermediate product between cyanuric chloride and iodide, also formed in the preparation of the latter (Klason).

#### METALLIC DERIVATIVES V. CYANURATES.

##### ALKYL DERIVATIVES.

**Formation.**—By the action of CNCl on sodium alcoholates, in which case normal cyanic ether is probably first formed and then polymerised (Hofmann a. Olshausen, *B.* 3, 271). CNBr or  $(CN)_3Br_3$  is conveniently substituted for CNCl in this reaction (Ponomareff, *B.* 18, 3264; Klason, *J. pr.* [2] 33, 131).

**Reactions.**—1. By distillation they are converted into the corresponding iso-ethers (Hofmann a. Olshausen).—2. Heated with dilute alkalis they assume the elements of water, and break down into alcohols and cyanuric acid.

**Trimethyl cyanurate**  $C_3H_3N_3O_3$ , i.e.

$(CN)_3$   $\begin{smallmatrix} \nearrow OMe \\ \nearrow OMe \\ \nearrow OMe \end{smallmatrix}$  Needles. Measurements (Hofmann (Fock), *B.* 19, 2065). [135°]. (265°) (Hofmann). Sl. sol. cold, v. sol. hot water (Hofmann a. Olshausen).  $PCl_5$  reacts forming  $(CN)_3Cl_3$  (Hofmann, *B.* 18, 2799). With  $HgCl_2$  it gives  $C_3H_3N_3O_3 \cdot HgCl_2$  (Ponomareff, *B.* 18, 3266).

**Diethyl-cyanuric acid**  $C_3H_3N_3O_4$ , i.e.

$(CN)_3$   $\begin{smallmatrix} \nearrow OEt \\ \nearrow OH \\ \nearrow OH \end{smallmatrix}$  Formed by the action of  $Ba(HO)_2 \cdot Aq$  or dilute  $NaHO \cdot Aq$  on the triethyl ether (Ponomareff, *B.* 18, 3267; Hofmann, *B.* 19, 2077; Mulder, *R.* 4, 91). Crystalline powder [160–180°] (Hofmann). Sublimes above 200° with decom-

position. Sl. sol. cold water or alcohol, insol. ether. Warmed with acids cyanuric acid is set free. The barium salt crystallises with 3aq from concentrated or with 12aq from dilute solutions. V. sol. water. The lead salt is insol. water.

**Triethyl cyanurate**  $C_3H_3N_3O_3$ , i.e.

$(CN)_3$   $\begin{smallmatrix} \nearrow OEt \\ \nearrow OEt \\ \nearrow OEt \end{smallmatrix}$

**Properties.**—An oily liquid crystallising at 0° (Mulder, *B.* 15, 70; *R.* 1, 195; 2, 133; 4, 91; Ponomareff, *B.* 15, 513). [29°–30°] (Hofmann, *B.* 19, 2074). (275°) (Klason, *J. pr.* [2] 33, 131). S. 0.7 in cold water. V. sol. alcohol, ether,  $CHCl_3$ , and  $CS_2$ . The aqueous solution at 0° deposits a crystalline hydrate containing 12aq (Mulder). With  $HgCl_2$  it forms the crystalline double salt  $C_3H_3N_3O_3 \cdot HgCl_2$  (Ponomareff), and with Br the compound  $C_3H_3N_3O_3 \cdot Br_3$  (Mulder).

**Reactions.**—1. Heated to 180°–200° it is converted into triethyl isocyanurate.—2. Conc. HCl sets free cyanuric acid.—3. Dilute  $NaHO$  or  $Ba(HO)_2$  removes one of the Et radicles forming diethyl-cyanuric acid.—4.  $PCl_5$  reacts with formation of  $(CN)_3Cl_3$ .—5. Heated with conc.  $NH_4Aq$  to 170°–180° amidogen replaces ethoxyl groups, ammeline and melamine being formed.

**Tri-iso-amyl cyanurate**  $C_{11}H_{21}N_3O_3$ , i.e.

$(CN)_3$   $\begin{smallmatrix} \nearrow OC_4H_9 \\ \nearrow OC_4H_9 \\ \nearrow OC_4H_9 \end{smallmatrix}$  Syrupy liquid. Undergoes intramolecular change above 360° (Klason).

**Triphenyl cyanurate**  $C_{18}H_{15}N_3O_3$ , i.e.

$(CN)_3$   $\begin{smallmatrix} \nearrow OPh \\ \nearrow OPh \\ \nearrow OPh \end{smallmatrix}$  Needles. [224°]. Distils unchanged. Insol. water and ether, sol. benzene.

Conc. HCl at 180° causes it to combine with the elements of water and break down into phenol and cyanuric acid (Hofmann a. Olshausen; Hofmann, *B.* 18, 765; 19, 2083; Klason, *Bihang till K. Svenska Vet. Akad. Handl.* 1885, 10, No. 7).

**Tri-p-nitrophenyl cyanurate**

$C_{21}H_{12}N_3O_9$ , i.e.  $(CN)_3$   $\begin{smallmatrix} \nearrow OC_6H_4NO_2 \\ \nearrow OC_6H_4NO_2 \\ \nearrow OC_6H_4NO_2 \end{smallmatrix}$  Pale yellow

tables. [194°] (Otto, *B.* 20, 2236).

**Tri-tolyl cyanurates**  $C_{24}H_{18}N_3O_3$ , i.e.

$(CN)_3$   $\begin{smallmatrix} \nearrow OC_6H_5 \\ \nearrow OC_6H_5 \\ \nearrow OC_6H_5 \end{smallmatrix}$

**Tri-o-tolyl cyanurate.** Pale yellow needles. [152°] (Otto).

**Tri-m-tolyl cyanurate.** Colourless microscopic needles. [225°] (Otto).

**Tri-p-tolyl cyanurate.** Silky colourless needles. [207°] (Otto); [265°] (Frentzel, *B.* 21, 411).

**Tri-eugenyl cyanurate**  $C_{33}H_{28}N_3O_3$ , i.e.

$(CN)_3$   $\begin{smallmatrix} \nearrow OC_8H_7O \\ \nearrow OC_8H_7O \\ \nearrow OC_8H_7O \end{smallmatrix}$

Pale yellow microscopic laminae. [122°] (Otto).

**Tri-thymyl cyanurate**  $C_{30}H_{28}N_3O_3$ , i.e.

$(CN)_3$   $\begin{smallmatrix} \nearrow OC_{10}H_{14} \\ \nearrow OC_{10}H_{14} \\ \nearrow OC_{10}H_{14} \end{smallmatrix}$

Pale yellow crystalline powder. [151°] (Otto).

**Tri-naphthyl cyanurates**  $C_{30}H_{21}N_3O_3$  i.e.

**Tri-( $\alpha$ -naphthyl cyanurate.** Greenish yellow powder, decomposing when heated without having a distinct melting-point.

**Tri-( $\beta$ -naphthyl cyanurate.** Light green powder (Otto).

**ALKOYL DERIVATIVES.**

**Formation.**—By the action of alkoyl chlorides on silver cyanurate (Ponomareff, *B.* 18, 3273; Senier, *C. J.* 49, 313).

**Tri-acetyl cyanurate**  $C_9H_3N_3O_6$  i.e.

Acetyl chloride and silver cyanurate are brought together in presence of ether, the mixture is afterwards evaporated, and the residue crystallised from chloroform. Minute crystals. [170°] with decomposition. Insol. ether; sl. sol.  $CHCl_3$ . Sol. warm water with decomposition into acetic and cyanuric acids (Ponomareff). A very similar compound to this was obtained by the action of  $AcCl$  on  $CNOAg$  in the preparation of cyanogen acetate or acetyl cyanate (Schutzenberger, *A.* 123, 271).

**Tri-benzoyl cyanurate**  $C_{24}H_{15}N_3O_6$  i.e.

Benzoyl chloride and silver cyanurate are heated together in closed tubes at 100°. The contents are extracted with  $CHCl_3$ , which on evaporation deposits tribenzoyl cyanurate in needles. On heating it decomposes. Sl. sol.  $CHCl_3$ ; insol. ether. Warmed with water it decomposes into cyanuric and benzoic acids (Senier).

**Normal thiocyanuric acid v. THIOCYANURIC ACID.**

**Normal amido-cyanuric acid.** *Ammelide.* *Melanurenic acid* (v. AMMELIDE).

**Normal diamido-cyanuric acid.** *Ammeline* (v. AMMELINE).

**HALOGEN DERIVATIVES v. AMMELINE.**

**ALKYL DERIVATIVES.**

**Di-methyl-di-amido cyanuric acid.** *Dimethyl ammeline*  $C_5H_7N_3O$  i.e.

Formed by heating di-methyl di-amido cyanuric chloride with dilute acids or by heating it with water at 200° (Hofmann, *B.* 18, 2770), or by heating tri-chloroacetonitril with aqueous methylamine at 120° (Weddige, *J. pr.* [2] 33, 89). Crystalline pp. Heated it decomposes without melting. V. sl. sol. boiling water; insol. alcohol and ether; sol.  $NaHOAc$ . Possesses acid and basic properties. ( $C_5H_7N_3O.HCl$ ). $PtCl_4$ .

**Ethyl diamido-cyanurate v. AMMELINE.**

**Ethyl ethylamido-amido-cyanurate.**

**Diethyl-ammeline**  $C_7H_{11}N_3O$  i.e.  $(CN)_3 \begin{array}{c} \diagup NH_2 \\ \diagdown NH_2 \end{array}$

Obtained by acting on  $(CN)_3Cl_2$  with  $NH_4Et$  and treatment of the resulting compound with  $HCl$  (Hofmann, *B.* 18, 2776).—**Platinochloride** ( $C_7H_{11}N_3O.HCl$ ). $PtCl_4$ .

VOL. II.

**Ethyl di-ethyl-di-amido-cyanurate.**

**Tri-ethyl-ammeline**  $C_9H_{15}N_3O$  i.e.  $(CN)_3 \begin{array}{c} \diagup NH_2 \\ \diagdown NH_2 \end{array}$

Formed by heating tri-ethyl-melamine with  $HCl$  (Hofmann, *B.* 2, 604). Syrupy liquid. Pt. salt:—( $C_9H_{15}N_3O.HCl$ ). $PtCl_4$ .

**Di-methyl-di-amido-cyanuric chlor-**

**ide**  $C_5H_9N_3Cl$  i.e.  $(CN)_3 \begin{array}{c} \diagup NHMe \\ \diagdown NHMe \end{array}$  Pre-

pared by the action of  $(CN)_3Cl_2$  on a solution of methylamine in methyl alcohol (Hofmann, *B.* 18, 2766; Klason, *Bihang till K. Svenska Vet. Akad. Handl.* 1885, 10, No. 7). Needles. [241°]. Insol. water, alcohol, and ether. Soluble with partial decomposition in glacial acetic acid. Reacts with water, forming dimethyl-ammeline. Ammonia converts it into dimethyl-melamine; methylamine turns it into trimethyl-melamine.

**Methylamido-methoxy-cyanuric**

**chloride**  $C_4H_7N_3OCl$  i.e.  $(CN)_3 \begin{array}{c} \diagup NHMe \\ \diagdown OMe \end{array}$

Formed in the same reaction with the last-mentioned compound (Hofmann, *B.* 18, 2771). Needles. [155°]. Sol. alcohol and ether.

**Phenyl diamidocyanurate.** *Phenyl*

**ammeline**  $C_9H_7N_3O$  i.e.  $(CN)_3 \begin{array}{c} \diagup NH_2 \\ \diagdown OPh \end{array}$  Insoluble

white crystalline powder. [245°] (Otto, *B.* 20, 2240).

**o-Tolyl diamidocyanurate.** *Tolyl*

**ammeline**  $C_{10}H_9N_3O$  i.e.  $(CN)_3 \begin{array}{c} \diagup NH_2 \\ \diagdown O(C_6H_5) \end{array}$

White crystalline solid. [225°] (Otto).

**ALKOYL DERIVATIVES v. BENZOYL AMMELINE.**

**Normal cyanuramide.** *Normal Melamine.*

$C_3H_7N_3$  i.e.  $(CN)_3 \begin{array}{c} \diagup NH_2 \\ \diagdown NH_2 \end{array}$

**Formation.**—1. Is one of the by-products in the preparation of melam by the action of heat on ammonium thiocyanate (Liebig, *A.* 10, 18, 53, 342; Volhard, *J. pr.* [2] 9, 29; Claus, *A.* 179, 121; *B.* 9, 1915; Jagger, *B.* 9, 1554).—2. By the action of aqueous ammonia at 100° on  $(CN)_3Cl_2$  (Hofmann, *B.* 18, 2765; Klason, *Bihang till K. Svenska Vet. Akad. Handl.* 1885, 10, No. 7).—3. From trimethyl thiocyanurate by the action of concentrated ammonia at 180° (Hofmann, *B.* 18, 2759).—4. Cyanamide polymerises by the action of heat to dicyanamide, and then passing to the trimolecular grouping, part forms melamine, and part with evolution of ammonia condenses to melam (Drechsel, *J. pr.* [2] 13, 331).—5. Melamine thiocyanate is formed when strong ammonia is made to act on pseudo-cyanogen sulphide at 160° (Ponomareff, *J. R.* 8, 215).—6. By the action of heat on guanidine carbonate in presence of phenol (Nencki, *J. pr.* [2] 17, 235).—7. Cyan-rælamidine breaks down when heated with  $HCl$  into melamine and  $HCN$  (Byk, *J. pr.* [2] 20, 346).

**Preparation.**—Trimethyl thiocyanurate is inclosed in a tube with an excess of concentrated solution of ammonia, and heated at a temperature of 180° for several hours. The temperature must not vary much, for if 200° or so is attained

Y

hydroxyl compounds are formed, and if it falls much below 180° the reaction is incomplete, and the melamine will be found to contain sulphur, rendering a second treatment with ammonia necessary. When the operation is successful the tube on cooling will contain an upper layer of methylmercaptan, while below in the aqueous portion large colourless crystals of melamine will have made their appearance. It may be further purified by recrystallisation from water (Hofmann).

**Properties.**—Monoclinic prisms (Weibull, *J. pr.* [2] 33, 292). Heated gently it sublimes. V. sl. sol. cold, v. sol. hot water. V. sl. sol. hot alcohol, sol. hot glycerin. Powerful base forming salts and decomposing many metallic salts.

**Reactions.**—1. Heated to low redness two molecules combine with evolution of 3NH<sub>3</sub> to form mellon (CN)<sub>2</sub>:(NH)<sub>2</sub>:(CN)<sub>2</sub>.—2. Heated with dilute HNO<sub>3</sub> the amidogen groups are successively replaced by hydroxyl giving ammeline, ammelide, and finally cyanuric acid (Knapp, *A.* 21, 256).—3. Fused with KHO potassium mellon and potassium cyanate are formed.—4. (CN)<sub>2</sub>Cl<sub>2</sub>, AcCl, and Ac<sub>2</sub>O are without action on melamine (Senier, *B.* 19, 312).

**Combinations.**—B'HCl 1½aq: needles (Liebig, *A.* 26, 187; Byk, *J. pr.* [2] 20, 315).—(B'HCl)<sub>2</sub>PtCl<sub>2</sub> 2aq (Hofmann, *B.* 18, 2760; Klason, *J. pr.* [2] 33, 293).—B'II<sub>2</sub>SO<sub>4</sub> 2aq also with 1½aq and 3aq. V. sl. sol. cold water. Test for melamine (Drechsel, *J. pr.* [2] 13, 332; Byk; Jaeger, *B.* 9, 1555).—B'H<sub>2</sub>SO<sub>4</sub>. Short rhombic prisms. Decomposed by water (Nencki, *J. pr.* [2] 17, 237).—B'H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>. V. sl. sol. water.—B'HSCN: prismatic crystals. V. sl. sol. cold water (Claus, *B.* 9, 1915; Ponomareff, *J. R.* 8, 215).—B'AgNO<sub>3</sub>. Crystalline pp. sol. hot water and ammonia (Liebig; Byk).—B'2AgNO<sub>3</sub>: needles (Zimmermann).

#### METALLIC DERIVATIVES.

By treating (CN)<sub>2</sub>(NH<sub>2</sub>)<sub>2</sub> 2AgNO<sub>3</sub> with ammonia a compound said to be diargentomelamine

#### ALKYL DERIVATIVES.

**Formation.**—1. By the final action of amines on (CN)<sub>2</sub>Cl<sub>2</sub> (Hofmann; Klason).—2. By the action of secondary amines on (CN)<sub>2</sub>Cl<sub>2</sub> (Hofmann, *B.* 18, 2773).—3. By the action of amines on trialkyl thiocyanurates (Hofmann).

**Reactions.**—1. Water (dilute acids) decomposes alkyl-melamines into cyanuric acid and amines.

**Dimethylcyanuramide.** Dimethylmelamine. C<sub>4</sub>H<sub>10</sub>N<sub>6</sub> i.e. (CN)<sub>2</sub>  $\begin{array}{c} \text{NHMe} \\ \text{NHMe} \end{array}$ . From diamido-cyanuric chloride by the action of ammonia. Crystalline base. Sol. water, sl. sol. alcohol and ether (Hofmann, *B.* 18, 2768).

**Trimethylcyanuramide.** Trimethylmelamine C<sub>6</sub>H<sub>12</sub>N<sub>6</sub> i.e. (CN)<sub>2</sub>  $\begin{array}{c} \text{NHMe} \\ \text{NHMe} \\ \text{NHMe} \end{array}$ . Base. [115°]. V. sol. water and alcohol.—(B'HCl)<sub>2</sub>PtCl<sub>4</sub>

Prisms.—B'(HCl)<sub>2</sub>PtCl<sub>4</sub>: long needles (Hofmann, *B.* 18, 2768 a. 2767; Klason, *J. pr.* [2] 33, 293).

**Hexamethylcyanuramide.** Hexamethylmelamine C<sub>6</sub>H<sub>18</sub>N<sub>6</sub> i.e. (CN)<sub>2</sub>  $\begin{array}{c} \text{NMe}_2 \\ \text{NMe}_2 \\ \text{NMe}_2 \end{array}$ . Base.

Needles. [171°–172°].—(B'HCl)<sub>2</sub>PtCl<sub>4</sub>: long needles. Sl. sol. water; sol. alcohol (Hofmann).

**Triethylcyanuramide.** Triethylmelamine C<sub>6</sub>H<sub>15</sub>N<sub>6</sub> i.e. (CN)<sub>2</sub>  $\begin{array}{c} \text{NHEt} \\ \text{NHEt} \\ \text{NHEt} \end{array}$ . Base. Needles

(from water) or prisms (from alcohol). [73°–74°]. Sl. sol. boiling water. Sol. alcohol, ether, and benzene.—(B'HCl)<sub>2</sub>PtCl<sub>4</sub>: insoluble needles.—B'(HCl)<sub>2</sub>PtCl<sub>4</sub>.—B'AgNO<sub>3</sub> (Hofmann, *B.* 18, 2775; Klason, *J. pr.* [2] 33, 294).

**Hexaethylcyanuramide.** Hexaethylmelamine C<sub>12</sub>H<sub>30</sub>N<sub>6</sub> i.e. (CN)<sub>2</sub>  $\begin{array}{c} \text{NEt}_2 \\ \text{NEt}_2 \\ \text{NEt}_2 \end{array}$ . Liquid.

Sol. alcohol and hydrochloric acid. Base. (B'HCl)<sub>2</sub>PtCl<sub>4</sub>. Crystalline. Sol. alcohol, sl. sol. water.—B'HClAuCl<sub>3</sub>: needles. V. sl. sol. water and alcohol (Hofmann, *B.* 18, 2778).

**Triperidylcyanuramide.** Triperidylmelamine C<sub>18</sub>H<sub>36</sub>N<sub>6</sub> i.e. (CN)<sub>2</sub>  $\begin{array}{c} \text{NC}_3\text{H}_7 \\ \text{NC}_3\text{H}_7 \\ \text{NC}_3\text{H}_7 \end{array}$ . Base.

Needles. [213°].—(B'HCl)<sub>2</sub>PtCl<sub>4</sub>. Heated with HCl at 150° it is decomposed into piperidine and cyanuric acid (Hofmann, *B.* 18, 2780).

**Triethylidencyanuramide.** Triethylidenmelamine C<sub>9</sub>H<sub>12</sub>N<sub>6</sub> i.e. (CN)<sub>2</sub>  $\begin{array}{c} \text{NC}_2\text{H}_4 \\ \text{NC}_2\text{H}_4 \\ \text{NC}_2\text{H}_4 \end{array}$ .

Formed by the action of CH<sub>3</sub>CHO on CNNH<sub>2</sub>. Sol. alcohol; insol. water, CS<sub>2</sub>, CHCl<sub>3</sub>, benzene, and aniline (Knop, *A.* 131, 253).

**Cyanuramido acetic acid.** Melamyl acetic acid. C<sub>5</sub>H<sub>8</sub>N<sub>4</sub>O<sub>4</sub> i.e. (CN)<sub>2</sub>  $\begin{array}{c} \text{NH}_2 \\ \text{NH}_2 \\ \text{NHCH}_2\text{COOH} \end{array}$ .

**Formation.**—By the action of chloro-acetic acid in presence of sodium ethylate on cyanamide (Drechsel, *J. pr.* [2] 11, 332).

**Properties.**—Crystalline powder. Decomposes without melting when heated. V. sl. sol. water, insol. alcohol and ether. Sol. alkaline solutions. Combines with bases, acids, and salts.

**Combinations.**—K salt: sol. water. Combines readily with CO<sub>2</sub>.—B'HCl: needles; v. sl. sol. water; insol. hydrochloric acid.—B'HNO<sub>3</sub>aq: laminae.—B'AgNO<sub>3</sub>aq: needles.—B'H<sub>2</sub>SO<sub>4</sub>: large prisms.

**Phenylcyanuramide.** Phenylmelamine C<sub>9</sub>H<sub>10</sub>N<sub>4</sub> i.e. (CN)<sub>2</sub>  $\begin{array}{c} \text{NHPh} \\ \text{NH}_2 \\ \text{NH}_2 \end{array}$ . Formed by heating

diamidocyanuric chloride with aniline at 150°. Prisms. [284°]. Sol. alcohol. (B'HCl)<sub>2</sub>PtCl<sub>4</sub> (Klason, *J. pr.* [2] 33, 295).

**Triphenylcyanuramide.** Triphenylmelamine C<sub>21</sub>H<sub>18</sub>N<sub>6</sub> i.e. (CN)<sub>2</sub>  $\begin{array}{c} \text{NHPh} \\ \text{NHPh} \\ \text{NHPh} \end{array}$ . Needles.

[228°]. (360° sublimes). Insol. usual solvents. Sl. sol. glacial acetic acid (Hofmann, *B.* 18, 3218; Klason).

**Pseudotriphenylcyanuramide.** *Triphenylmelamine*  $C_{18}H_{15}N_6$ . Formed by the destructive distillation of tribenzoyl-melamine. Yellow crystalline insoluble powder. Sol. hot phenol. [c. 360°] (Gerlich, *J. pr.* [2] 13, 286; Drechsel, *B.* 21, 1549).

**Tetraphenylcyanuramide.** *Tetraphenylmelamine*  $C_{24}H_{18}N_6$  i.e.  $(CN)_3 \begin{matrix} \diagup NPh_2 \\ \diagdown NPh_2 \\ | NH_2 \end{matrix}$

**Formation.**—1. By heating diphenylguanidine to 170°–180° (Hofmann, *B.* 7, 1787).—2. By the action of  $CNCl$  on aniline at 170°–180° (Weith a. Ebert, *B.* 8, 912).

**Properties.**—Needles. [217°]. Insol. water; v. sl. sol. ether. Mono-acid base. Heated alone it decomposes into  $NH_3$ , mono-, and diphenylamine and  $HCN$ ; with  $HCl$  or  $KIO$  the products are  $CO_2$ ,  $NH_3$ , and aniline. Hydrochloride:— $BHCl$ . Pt salt:— $(BHCl)_2PtCl_6$ .

**Hexaphenylcyanuramide.** *Hexaphenylmelamine*  $C_{36}H_{24}N_6$  i.e.  $(CN)_3 \begin{matrix} \diagup NPh_2 \\ \diagdown NPh_2 \\ | NPh_2 \end{matrix}$

big tables (from nitrobenzene). [above 300°]. Insol. usual solvents. Does not combine with  $HCl$ . At 200°  $HCl$  decomposes it into diphenylamine and cyanuric acid (Hofmann, *B.* 18, 3219).

**Tri-p-tolylcyanuramide.** *Tri-p-tolylmelamine*  $C_{24}H_{18}N_6$  i.e.  $(CN)_3 \begin{matrix} \diagup NHCH_3 \\ \diagdown NHCH_3 \\ | NHCH_3 \end{matrix}$  Indiferent. Insoluble. Needles. [283°] (Klason, *J. pr.* [2] 33, 294).

**Triamido-tritolylcyanuramide.** *Tritolylmelamine*  $C_{24}H_{18}N_6$  i.e.  $(CN)_3 \begin{matrix} \diagup NHCH_2CH_3 \\ \diagdown NHCH_2CH_3 \\ | NHCH_2CH_3 \end{matrix}$

Formed by the action of tolylene-diamine on cyanuric chloride (Fries, *C.* 49, 314 a. 739). The two intermediate compounds *mono-* and *di-tolylene-amido-cyanuric chloride* are also formed in this reaction (Fries).

**Trinaphthylcyanuramide.** *Trinaphthylmelamine*  $C_{36}H_{24}N_6$  i.e.  $(CN)_3 \begin{matrix} \diagup NHCH_2CH_3 \\ \diagdown NHCH_2CH_3 \\ | NHCH_2CH_3 \end{matrix}$

Formed by the action of (a) and (b) naphthylamine on  $(CN)_3Cl$  (a)-*trinaaphthyl-melamine* [223°] and (b)-*trinaphthyl-melamine* [209°] together with the (a) and (b) *mono-* and *dinaphthylamido-cyanuric chlorides* are formed (Fries).

**Triphenyl-tri-amido-cyanuramide.** *Triamylmelamine*  $C_{24}H_{18}N_6$  i.e.  $(CN)_3 \begin{matrix} \diagup NH.NH.Ph \\ \diagdown NH.NH.Ph \\ | NH.NH.Ph \end{matrix}$

Obtained together with the *mono-* and *diphenylhydrazine-cyanuric chloride* by the action of phenylhydrazine on  $(CN)_3Cl_2$  (Fries).

**ALKOYL DERIVATIVES.**  
**Formylcyanuramide.** *Formylmelamine*  $C_4H_5N_3O$  i.e.  $(CN)_2 \begin{matrix} \diagup NH(CHO) \\ \diagdown NH_2 \end{matrix}$

Prepared by the action of oxalic ether on cyanamide (Mulder, *B.* 7, 1631). Insol. water. Decomposed by acids or long boiling with water.

**Tribenzoyl-cyanuramide.** *Tribenzoylmelamine*  $C_{24}H_{15}N_3O_3$  i.e.  $(CN)_3 \begin{matrix} \diagup NHBz \\ \diagdown NHBz \\ | NHBz \end{matrix}$

by polymerisation of benzoyl-cyanamide. Yellow powder. [275°]. Insol. water, alcohol, and ether. Heated the products are  $CO_2$ ,  $HCl$ , benzonitrile, dibenzoyldicyanamide, and pseudotriphenyl-melamine (Gerlich, *J. pr.* [2] 13, 272).

**Condensed cyanuramide compounds.**  
*Melam*  $C_6H_8N_4$  i.e.  $(CN)_2 \begin{matrix} \diagup NH_2 \\ \diagdown NH_2 \\ | NH_2 \end{matrix}$

**Preparation.**—Crude melam is obtained by the action of heat on ammonium thiocyanate  $16CNSNH_4 = 2C_4H_8N_4 + 5(NH_4)_2S + 4CS_2 + 3H_2S$ . A strong heat should be applied, best by means of a metal bath, rising quickly to 300°, and continued till the evolution of gas ceases (Liebig, *A.* 10, 10; Claus, *A.* 179, 118). The product consists of melam thiocyanate and melam. It is washed by boiling with water and afterwards with cold dilute potash. Then it is dissolved in hot dilute  $HCl$  and reprecipitated by  $KIO$  (Klason, *J. pr.* [2] 33, 286).

**Properties.**—An indifferent insoluble powder. Slightly sol. acids and hot alkalis. Heated alone it yields  $NH_3$  and mellon; with dilute acids or alkalis it gives  $NH_3$  and ammeline; with conc.  $HNO_3$  cyanuric acid.

*Melem*  $C_6H_8N_4$  i.e.  $(CN)_2 \begin{matrix} \diagup NH_2 \\ \diagdown NH_2 \\ | NH_2 \end{matrix}$

Prepared by digesting 1 pt. of crude melam with 4 pts.  $KHO$  and 80 pts. of water for 24 hrs. at 100°. Melem remains unacted upon, while melam is converted into ammeline. By heating with conc.  $KHO$  melem forms ammeline and  $NH_3$  (Klason, *J. pr.* [2] 33, 287).

*Mellon*  $C_6H_8N_4$  i.e.  $(CN)_2 \begin{matrix} \diagup NH \\ \diagdown NH \\ | NH \end{matrix}$

This compound, which is the homologous trimolecular modification of cyanogen cyanamide  $(CN)_3NH$ , of which metallic derivatives are known (Bannow), is formed among the products of the action of heat on numerous cyanogen derivatives—pseudothiocyanogen, mercuric thiocyanate, ammonium thiocyanate, melam, melamine, ammeline, ammeline, diamido-cyanuric chloride, cyanamide, etc. (Liebig, *A.* 10, 4; 50, 312; Laurent a. Gerhardt, *A. Ch.* [2] 19, 85; Vœlckel, *P.* 61, 375). A light yellow powder. Insol. water, acids, and alkalis. Heated alone it breaks down into  $N$ ,  $C_2N_2$ , and  $HCl$ ; with  $KIO$ , into  $NH_3$  and mellonpotassium, and with  $HNO_3$ , into cyanic acid and  $NH_3$ .

*Mellonhydride*  $C_6H_8N_4$  i.e.  $N \begin{matrix} \diagup (CN)_2 = NH \\ \diagdown (CN)_2 = NH \\ | (CN)_2 = NH \end{matrix}$

**Preparation.**—The potassium salt of mellonhydride is formed either by heating a mixture of mellon and  $KHO$  in presence of cyanogen, or by melting potassium thiocyanate together with melam, mellon, or  $SbCl_3$  (Liebig, *A.* 95, 271; Volhard, *J. pr.* [2] 9, 29; Klason, *J. pr.* [2] 33, 289). The potassium salt is converted into a

copper compound, and this decomposed by  $H_2S$  gives an aqueous solution of the free hydride.

**Properties.**—A strongly acid solution. Decomposes carbonates. All attempts to isolate the free hydride have been unsuccessful. It forms primary, secondary, and tertiary salts.

**Salts.**— $KH.C_2N_3$ . —  $K_2HC_2N_3$ . 3aq. —  $K_3C_2N_3$ . 5aq. Needles. Bitter. S. 2.7 in cold water. —  $Ca_2(C_2N_3)_2$ . 4aq. —  $Ba_2(C_2N_3)_2$ . 6aq. —  $Cu_2(C_2N_3)_2$ . 5aq. —  $Ag_2C_2N_3$ .

**Cyamelicuric acid**  $C_4H_2N_2O_5 \cdot \frac{1}{2}H_2O$  i.e.

**Formation.**—By the long-continued digestion of potassium mellon with KHO and liberation of the free acid from the salt so obtained by HCl (Henneberg, A. 73, 235; Volhard, J. pr. [2] 9, 50).

**Properties.**—Powerful tribasic acid. White powder. V. sl. sol. water. Heated alone it yields cyanic and cyanuric acids and mellon.

**Salts.**— $K_3A'''$  3aq: needles. Sol. water with strong alkaline reaction (Liebig, A. 95, 281). —  $KH.A'''$  2aq. —  $Ba_2A'''$  2aq. —  $Ag_2A'''$ .

**Isocyanuric acid**  $(CO)_2 \begin{smallmatrix} \text{NH} \\ \text{NH} \end{smallmatrix}$ . The hypothetical acid corresponding to the isocyanuric ethers.

#### ALKYL DERIVATIVES.

**Formation.**—1. By the distillation of a mixture of potassium cyanurate and alkyl sodium sulphate (Wurtz, A. Ch. [3] 42, 57).—2. By the action of heat on alkylacetylurea alkyl isocyanurates are formed, together with acetamido and other products (Hofmann, B. 14, 2728).—3. From dialkylureas by heating (Wurtz, J. 1856, 700).—4. By the action of alkyl iodides on silver or potassium cyanurate (Habich a. Limpricht, A. 109, 112; Ponomareff, B. 18, 3270).—5. By polymerisation of isocyanic ethers or the intramolecular change of normal cyanuric ethers (Hofmann a. Olshausen, B. 3, 271).

**Reactions.**—1. The action of water (heating with dilute acids) causes the isocyanuric ethers to break down like the isocyanic ethers into  $CO_2$  and amines (Wurtz).—2. With  $PCl_5$  isocyanuric ethers do not give cyanuric chloride, but chloroalkyl substitution compounds (Hofmann, B. 18, 2800).

**Dimethylisocyanuric acid**  $C_4H_6N_4O_5$ , i.e.  $(CO)_2 \begin{smallmatrix} \text{NMe} \\ \text{NMe} \end{smallmatrix}$ . Needles. Crystal measurements (Hofmann, B. 19, 2071). [222°]. Its salts are not very stable. Ammoniacal solution gives with  $CuSO_4$  a violet  $Cu$  salt. Silver salt v. sl. sol. water (Hofmann, B. 14, 2728; 19, 2069).

**Trimethylisocyanurate**  $C_6H_9N_3O_3$ , i.e.  $(CO)_3 \begin{smallmatrix} \text{NMe} \\ \text{NMe} \end{smallmatrix}$ . Prisms. Crystals measured (Hofmann, B. 19, 2067). [175°–176°]. (274°). Insol. cold, sl. sol. hot water. Sol. alcohol. Treated with  $PCl_5$  the compound  $(CN)_3(OCH_2Cl)$  is formed. —  $B'HgCl_2$  crystals (Wurtz; Hofmann a.

Olshausen; Ponomareff, B. 18, 3271; Hofmann, B. 18, 2300; 19, 2093).

**Combinations with formamide** (Gantier, A. 149, 313)  $(CN)_2(NMe)_2.HCONH_2$ . Obtained by the oxidation of acetonitrile. [175° with partial sublimation]  $(CN)_2(NMe)_2.(HCO)_2NH$ . [163°]. (168°).

**Diethylisocyanuric acid**  $C_6H_{11}N_3O_5$ , i.e.

$(CO)_2 \begin{smallmatrix} \text{NEt} \\ \text{NEt} \end{smallmatrix}$ . Hexagonal prisms. Measurements

(Hofmann, B. 19, 2078). [173°]. Sl. sol. cold, sol. hot, water. Sol. alcohol, ether, ammonia, and alkalis. —  $B'Ba$  aq: sol. water. —  $B'Ag$ : needles, ppd. by ammoniacal  $AgNO_3$ . Copper salt rose-coloured (Habich a. Limpricht, A. 109, 112; Wurtz, J. 1856, 700; Ponomareff, B. 18, 3270).

**Triethyl-isocyanurate**  $C_6H_{13}N_3O_3$ , i.e.

$(CO)_3 \begin{smallmatrix} \text{NEt} \\ \text{NEt} \end{smallmatrix}$ . Rhombic prisms (Hofmann, B. 19,

2076). [95°]. (276°). Distills with steam. Sol. hot water, alcohol, and acids.  $PCl_5$  has no action, and  $KHO$  decomposes the ether with difficulty. Heated with  $Ba(OH)_2$  aq it yields  $CO_2$  and triethylbiuret, and similarly with sodium alcoholate ethylene, ethylamine, triethylguanidine, and triethylbiuret are formed (Hofmann, J. 1861, 516). Chlorine forms substitution derivatives (Wurtz; Habich a. Limpricht; Ponomareff; Gnl, A. 137, 127).

**Tetrachlorotriethyl isocyanurate**

$C_6H_3Cl_4N_3O_3$ . Crystals. Insol. water; sol. alcohol. Not ppd. by  $AgNO_3$ . Compounds containing less Cl are obtained by the action of alcoholic potash (Habich a. Limpricht, A. 109, 109).

**Tribenzyl isocyanurate v. BENZYL-CYANURATE.**

**Triphenyl isocyanurate**  $C_{18}H_{15}N_3O_3$ , i.e.  $(CO)_3 \begin{smallmatrix} \text{NPh} \\ \text{NPh} \end{smallmatrix}$ .

**Formation.**—1. The NH groups of triphenyl-isocyclamine are replaced by oxygen by treatment with alcohol and HCl.—2. Phenyl isocyanate is polymerised to isocyanurate by heating for 3 hrs. at 100° with dry potassium acetate (Hofmann, B. 3, 268; 18, 765 a. 3225).

**Properties.**—Prisms. [274°–275°]. Distills mostly unchanged. Insol. water; sol. hot alcohol.

#### CARBOXYLIC DERIVATIVES.

By the action of ethyl chloroformate  $ClCOOEt$  on potassium cyanate, besides carboxyethyl-carbamio ether, three carboxyethyl derivatives of isocyanuric acid have been obtained. These are triethyl isocyanuricarboxylate, and two derivatives intermediate between that compound and isocyanuric ether. By distillation they lose  $CO_2$  and are converted into isocyanurates (Wurtz a. Henninger, B. 44, 26).

**Triethyl isocyanuricarboxylate**

$C_{17}H_{21}N_3O_7$ , i.e.  $(CO)_2 \begin{smallmatrix} \text{NCOOEt} \\ \text{NCOOEt} \end{smallmatrix}$ . Crystals. [118°–119°].

mine and alkylisocyanurate. Both are prepared by treatment of triphenylisocammelamine with HCl, the isocammelamine being first formed (Hofmann, B. 18, 3224).

**Formation.**—By heating solutions of alkylisocyanamides, whereby polymerisation takes place (Hofmann, B. 2, 602).

**Reactions.**—Heated with dilute acids the alkyl isocammelamines yield NH<sub>3</sub> and become converted into isocyanurates (Hofmann).

**Trimethylisocammelamine**  $C_6H_9N_3$ , 3aq. i.e.  $(CNEt)_3(NH)$ , 3aq. Needles. [179°]. Commences to sublime above 100°. Sol. water and alcohol, insol. ether. Reaction alkaline. HCl acts in the first instance, forming trimethylisocammelide and then trimethylisocyanurate.—B<sup>1</sup>(HCl)<sub>2</sub>PtCl<sub>4</sub>. Laminae. V. sl. sol. water and alcohol.—B<sup>1</sup>(HCl)<sub>2</sub>AuCl<sub>3</sub>. Needles (Hofmann, B. 3, 261; 18, 2784; Baumann, B. 6, 1872).

**Triethylisocammelamine**  $C_8H_{11}N_3$ , 4aq. i.e.  $(CNEt)_3(NH)$ , 4aq. Crystals. [92°]. V. sol. water and alcohol. Reaction alkaline. HCl reacts forming successively triethylisocammelamine, triethylisocammelide, and triethylisocyanurate.—Salts: B<sup>1</sup>(HCl)<sub>2</sub>PtCl<sub>4</sub>. Sol. water.—B<sup>1</sup>(HCl)<sub>2</sub>AuCl<sub>3</sub>. Needles. Sl. sol. water and alcohol (Hofmann, B. 2, 602; 3, 266; 18, 2788).

**Tribenzylisocammelamine**  $C_{18}H_{15}N_3$ , i.e.  $(CNC_6H_5)_3(NH)$ . Laminae [higher than benzylisocyanamide].—B<sup>1</sup>(HCl)<sub>2</sub>. Needles. Sl. sol. water (Stakosch, B. 5, 694).

**Triphenylisocammelamine**  $C_{18}H_{15}N_3$ , i.e.  $(CNPh)_3NH$ . Needles. [185°]. V. sl. sol. hot water, sol. alcohol and ether. HCl reacts forming successively triphenylisocammelamine, triphenylisocammelide, and triphenylisocyanurate.—B<sup>1</sup>(HCl)<sub>2</sub>PtCl<sub>4</sub>. Needles (Hofmann, B. 3, 267; 18, 3223).

**Normal-iso Cyanuric acids (hypothetical).**

**ALKYL DERIVATIVES.**

**Phenyliso-dynormal cyanuric acid.**  
**Monophenylisocyanuric acid**

action of conc. HCl on Rathke's triphenylisocammelamine. Flat needles. [285°-289°]. V. sol. hot, v. sl. sol. cold water (Rathke, B. 20, 1070; 21, 863).

**Diphenyliso-normal cyanuric acid**

ing *u*-triphenylmelamine with conc. HCl at 160°. The phenylamido group is thus replaced

by hydroxyl and the imido-groups by oxygen. Needles or laminae. [261°]. Insol. water, sol. alcohol, v. sl. sol. ether. With conc. HCl at 280° it breaks down into CO<sub>2</sub>, NH<sub>3</sub>, and aniline. C<sub>21</sub>H<sub>11</sub>AgN<sub>3</sub>O<sub>3</sub>, crystalline pp. formed on addition of AgNO<sub>3</sub> to a solution of the sodium salt (Hofmann, B. 18, 3230).

Normal-iso ammelines (hypothetical).

ALKYL DERIVATIVES.

*Phenylnormalamido-diphenyliso-amido-cyanuric acid*. Triphenylammeline

by treatment of ethyltriphenylthioammeline hydrobromide, a compound prepared by the action of ethyl bromide on triphenyl-thioammeline, with alcoholic potash. Colourless laminae. [275°]. V. sl. sol. alcohol, sl. sol. chloroform. Conc. HCl at 160° converts it into phenyliso-dinormal-cyanuric acid (Rathke, B. 20, 1069; 21, 868).

*Phenylnormalamido-phenyliso-amido-phenylisocyanurate*. Triphenyl-

pared by acting on Hofmann's *u*-triphenylmelamine with HCl at 100°. Crystals. [265°]. Heated further with HCl it is converted into diphenyl iso-normal-cyanuric acid (Hofmann, B. 18, 3229).

Normal-iso melamines (hypothetical).

ALKYL DERIVATIVES.

*Phenylnormal-diphenyliso-melamine. u-Triphenyl-melamine*

**Formation.**—By the desulphurisation of monophenylthiourea by HgO in alcoholic solution.

**Properties.**—Needles. [217°]. Insol. water, sl. sol. ether. sol. chloroform, sol. dilute acids and reprecipitated by alkalis.

**Reactions.**—By the action of HCl it is converted at 100° into Hofmann's isonormal triphenylammeline, and at 150°–200° into diphenyl isonormal cyanuric acid (Hofmann, B. 18, 3226).

*Diphenyl-melamine* C<sub>18</sub>H<sub>11</sub>N<sub>3</sub>. A by-product in the preparation of Rathke's triphenylmelamine. Formed together with aniline when in that process the further action of alcoholic ammonia causes the isonormal triphenylmelamine to change into the normal isomeride. It may possibly prove to be a normal compound. [202°–204°]. (B·HCl), PtCl<sub>4</sub> (Rathke, B. 21, 873).

*Triphenylmelamine*. (?) *Diphenylnormal phenylisomelamine*

**Formation.**—By the action of alcoholic ammonia on ethyl triphenyl-thioammeline hydrobromide, the reaction being: C<sub>21</sub>H<sub>11</sub>Ph<sub>3</sub>SET + NH<sub>3</sub> = C<sub>21</sub>H<sub>11</sub>Ph<sub>3</sub>NH<sub>2</sub> + EtSH. Diphenylammeline, aniline, and normal triphenylmelamine are formed in the same reaction (Rathke, B. 20, 1071; 21, 868).

**Properties.**—Prisms. [221°]. Sol. hot alcohol. Base. The hydrochloride and sulphate are soluble, the nitrate is sl. sol. water.

**Reactions.**—1. Heated with alcohol and ammonia it changes to normal triphenylmelamine. 2. Heated with conc. HCl at 125° it is converted into Rathke's triphenylammeline, and at higher temperatures into phenyl iso-dinormal-cyanuric acid.

**Other isomerides of cyanuric acid.**

The members of this division of trimolecular compounds are so little known that it would be premature to attempt to assign to them structural formulae.

The (a) and (b) *Cyanuric acids* (Herzig, B. 12, 170) are not included, recent investigation having shown that when purified they are in all respects identical with each other and with ordinary cyanuric acid (Senier, C. J. 49, 693 a. 743).

*Cyameliide* (CNOH).<sup>1</sup>

**Formation.**—1. Liquid cyanic acid polymerises slowly at 0°, and instantly at higher temperatures with evolution of heat forming cyamelide. This reaction takes place when cyanates are treated with anhydrous acids (Liebig a. Wohler, P. 15, 561; 20, 384; Trost a. Hautefeuille, J. 1869, 99; Weltzien, A. 132, 222).—2. Is formed, together with cyanuric acid, by the action of (CN)<sub>2</sub>Cl<sub>2</sub> on water (Liebig, P. 15, 563). Cf. Mulder (L. 6, 199).

**Properties.**—Tasteless, inodorous solid. Insol. water, alcohol, ether, and dilute acid, sol. KHOaq or NH<sub>4</sub>HOaq, cyanurate being formed on evaporation. Heated alone it evolves cyanic acid. Heated with H<sub>2</sub>SO<sub>4</sub> it is converted into ordinary cyanuric acid. Cyamelide may possibly prove to be free isocyanuric acid (Klason, J. pr. [2] 33, 129).

*Cyanilic acid* C<sub>2</sub>N<sub>2</sub>O<sub>2</sub>H<sub>2</sub>O.

This compound is so nearly related to cyanuric acid that when further studied it may prove to be identical with it. Mellon is heated together with HNO<sub>3</sub>, and the product extracted with water. Recrystallised from water it consists of pearly laminae, or from HNO<sub>3</sub> of four-sided prisms. By solution in H<sub>2</sub>SO<sub>4</sub> it is converted into cyanuric acid, which falls on the addition of water. It has the same proportion of water of crystallisation, and the crystals effloresce just in the same manner as cyanuric acid. With AgNO<sub>3</sub> it forms a salt AgH<sub>2</sub>C<sub>2</sub>N<sub>2</sub>O<sub>2</sub>, corresponding to a similar cyanurate. Its solubility in water was, however, found to be greater than that of cyanuric acid, and its crystalline form to be different (Liebig, A. 10, 34).

**Fulminuric acid**  $\text{HC}_2\text{H}_2\text{N}_3\text{O}_2$  *is.*

**Formation.**—By heating fulminating mercury (not fulminating silver) with an aqueous solution of alkaline chlorides or iodides (Liebig, *A.* 95, 282; Schischkow, *A.* 97, 53; 101, 213), or with water (Ehrenberg, *J. pr.* [2] 32, 98), or in tubes with alcoholic ammonia (Steiner, *B.* 9, 781). The potassium or ammonium salt thus obtained is converted into the lead or silver compound which suspended in water is treated with  $\text{H}_2\text{S}$ . The aqueous solution which results deposits the free fulminuric acid as an indistinct crystalline powder on spontaneous evaporation.

**Properties.**—Small anhydrous colourless prisms from alcohol. Sol. water, alcohol, and ether. Solutions have an acid reaction, and give a characteristic deep blue pp. with ammonio copper sulphate.

**Reactions.**—1. Heated it explodes at  $145^\circ$ .—2. Heated with dilute acids or alkalis  $\text{NH}_3$ ,  $\text{CO}_2$  and  $\text{H}_2\text{C}_2\text{O}_4$  are formed (Steiner, *B.* 5, 381).—3. The silver salt heated with conc.  $\text{HCl}$  separates one of its N atoms as  $\text{NH}_4\text{OH}$  (Ehrenberg).—4. Two atoms of N are evolved as ammonia by heating with soda lime.—5. With chloride of lime it forms  $\text{C}(\text{NO})\text{Cl}_2$ .—6. With  $\text{H}_2\text{SO}_4$  nitroacetonitrile is formed, and in presence of  $\text{HNO}_3$  tri-nitroacetonitrile.

**Halogen derivatives.**—Chlorofulminuric acid  $\text{C}_2\text{H}_2\text{ClN}_3\text{O}_2$ . Salts  $\text{AgC}_2\text{HClN}_3\text{O}_2$ ,  $\text{AgC}_2\text{ClN}_3\text{O}_2$ . Bromofulminuric acid  $\text{C}_2\text{H}_2\text{BrN}_3\text{O}_2$  (Ehrenberg, *J. pr.* [2] 32, 111).

**Metallic derivatives.**— $\text{NH}_4\text{A}'$ : prisms, sol. water, insol. alcohol (Liebig).— $(\text{NH}_4\text{A}')_2(\text{Hg}_2\text{SCN})_2$  [ $150^\circ$ ] (Ehrenberg, *J. pr.* [2] 30, 64).— $\text{NH}_4\text{A}'\text{HgSCN}$  [ $161^\circ$ ].— $(\text{NH}_4\text{A}')_2\text{Hg}(\text{SCN})_2$  [ $156^\circ$ ].— $\text{KA}'$ : prisms, sol. water, insol. alcohol. Explodes at  $225^\circ$  (Schischkow).— $\text{MgA}'_2$ , 5aq: needles (Steiner).— $\text{BaA}'_2$ , 2aq: prisms (Liebig).— $\text{ZnA}'_2$ , 5aq: needles (Steiner).— $\text{HgA}'_2$ : crystalline powder (Steiner).— $\text{HgA}'_2\text{HgO}$  (Steiner).— $\text{PbA}'_2$ , 2aq: needles (Steiner).— $\text{CuA}'_2$ , 4aq: emerald green rhombs.  $\text{CuA}'_2\cdot 4\text{NH}_3$ : characteristic deep blue pp. Prisms. Insol. water, v. sl. sol. ammonia.— $\text{AgA}'$  (Liebig).

**Alkyl derivatives.**—An unstable oil  $\text{C}_6\text{H}_{11}\text{NO}_2$  is obtained by passing  $\text{HCl}$  into a mixture of potassium fulminurate and alcohol. It combines with  $\text{NH}_3$  and amines— $\text{C}_2\text{H}_5\text{NO}_2\cdot\text{NH}_3$  [ $152^\circ$ ].  $\text{C}_2\text{H}_5\text{NO}_2\cdot\text{NH}_2\text{Ph}$ : needles. [ $81^\circ$ ] (Ehrenberg, *J. pr.* [2] 32, 106; Schischkow, *A.* 97, 61).

**Isfulminuric acid**  $\text{C}_2\text{H}_2\text{N}_3\text{O}_2$ .

**Formation.**—Together with other products by the action of aqueous ammonia on an ethereal solution of fulminic acid obtained by leading  $\text{HCl}$  at  $0^\circ$  into a mixture of fulminating mercury and ether. The aqueous solution on spontaneous evaporation deposits fulminuramide, and from the solution by further treatment isofulminuric acid is obtained.

**Properties.**—Pulverulent. Chars without melting when heated. V. sol. water and alcohol. Gives no pp. with ammonio-cupric sulphate.

**Salts.**— $\text{NH}_4\text{A}'$ — $\text{BaA}'_2$ — $\text{AgA}'$ : amorphous pp., insol. cold water (Ehrenberg, *J. pr.* [2] 30, 48).

**Fulminuramide.**— $\text{C}_2\text{H}_2\text{NH}_2\text{N}_3\text{O}_2$ : long minute needles.— $(\text{B}')_2\text{CuO}_2\text{NH}_2$ : light blue pp.— $\text{B}'_2\text{AgNO}_2$ : needles (Ehrenberg).

**Metafulminuric acid**  $\text{C}_2\text{H}_2\text{N}_3\text{O}_2\cdot 3\text{H}_2\text{O}$ .

**Formation.**—By the action of dilute  $\text{H}_2\text{SO}_4$  on sodium fulminate. The product is extracted with ether which evaporated in a current of air below  $30^\circ$  deposits the metafulminuric acid in needles. The solution contains isocyanilic acid which is formed in the same reaction.

**Properties.**— $[81^\circ]$ . Anhydrous acid explodes at  $106^\circ$ . Tribasic acid. V. sol. alcohol and benzene, less so in water and ether. Decomposes gradually with evolution of  $\text{HCN}$ .

**Reactions.**—1.  $\text{KHO}$  or water at  $130^\circ$  breaks it down into  $\text{CO}_2$  and  $\text{NH}_3$ .—2. Heated with conc.  $\text{HCl}$ ,  $\text{NH}_4\text{OH}$  is formed.—3. Gradually changes into  $(\beta)$ -isofulminuric acid on standing.

**Salts.**— $\text{NH}_4\text{H}_2\text{A}''$ — $(\text{NH}_4)_2\text{HA}''$ —

$\text{H}_2\text{A}''(\text{NH}_4\text{Me})_2$ : yellow needles.— $\text{KA}''$ — $\text{PbHA}''$ aq: lemon-yellow insol. pp.— $\text{Ag}_2\text{HA}''$ aq. On adding  $\text{AgNO}_3$  to the aqueous solution the silver salt falls as a characteristic cinnamon red, at first gelatinous, precipitate. Explodes when dry at  $86^\circ$  (Scholvién, *J. pr.* [2] 32, 464).

**( $\beta$ )-Isofulminuric acid**  $\text{C}_2\text{H}_2\text{N}_3\text{O}_2\cdot 2\text{H}_2\text{O}$ . Metafulminuric acid changes gradually on standing, being converted into this metameric modification. Needles, from water. [ $188^\circ$ ]. [ $196^\circ$  anhydrous, with decomposition]. Sol. water and alcohol.

**Salts.**— $\text{NH}_4\text{A}'$ — $\text{BaA}'_2$ — $\text{AgA}'$  insol. pp., crystallises in needles (Scholvién, *J. pr.* [2] 32, 474).

**Isocyanilic acid**  $(\text{CNOH})_2$ .

**Formation.**—To the ethereal mother-liquor from which metafulminuric acid has been separated, water is added and the evaporation continued, when isocyanilic acid comes out in needles. It may be recrystallised from water.

**Properties.**—Does not explode on heating. Sol. hot water, alcohol, and ether. Gives no pp. in aqueous solution on adding  $\text{AgNO}_3$  or  $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2$  or  $\text{CuSO}_4$ . Heated with conc.  $\text{KHO}$  the solution is coloured deep red violet, and on the addition of alcohol a salt of the same colour is ppd. This red violet compound in aqueous solution gives with  $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2$ , a bright red violet explosive lead salt  $\text{Pb}_2\text{C}_2\text{H}_2\text{N}_2\text{O}_4$  (Scholvién, *J. pr.* [2] 32, 476).

A. S.

**CYANIDES** (including SULPHOCYANIDES and SELENOCYANIDES). **Binary compounds of cyanogen.** In this article only metallic cyanides are described. Alkyl cyanides are described as *nitriles*; e.g. for description of  $\text{CH}_3\cdot\text{CN}$  v. ACETONITRILE.

Cyanogen forms binary compounds with above 30 metals; most of these cyanides form several, some form very many, double cyanides; some of the double cyanides are best regarded as metallic derivatives of acids composed of H combined with metals and the atomic group CN (v. post). Cyanogen also forms binary compounds with the non-metals Br, Cl, I, P, Se, and S. Of these compounds,  $\text{CNBr}$ ,  $\text{CNCl}$ , and  $\text{CNI}$  are described under CYANOACID (p. 312, §18); the others are described under CYANOGEN as *Cyanogen phosphide*, &c.

The simple cyanides may be regarded as derived from cyanhydric acid  $\text{HCN}$ , by replacing H by metals; the general formulae expressing

their compositions are  $\text{NC.M}$ ,  $(\text{NC})_2\text{M}^{\text{II}}$ ,  $(\text{NC})_3\text{M}^{\text{III}}$ , &c.

Alkali cyanides are formed by the direct union of cyanogen with alkali metals, by reactions between  $\text{HCNAq}$  and alkali oxides, by strongly heating nitrogenous organic matter with alkali carbonate. Many other cyanides are obtainable from alkali cyanides by double decomposition.

Alkali and alkaline earth cyanides are soluble in water; the other simple cyanides, with the exception of  $\text{HgCy}_2$ , are insoluble in water, but may dissolve in solutions of alkali cyanides with production of double cyanides.

Alkali cyanides are very easily decomposed with evolution of  $\text{HCN}$ , passage of a current of air free from  $\text{CO}_2$  suffices to effect this change. Some of the insoluble cyanides are readily decomposed by dilute acids, e.g.  $\text{PbCy}_2$  and  $\text{ZnCy}_2$ ; others are very stable towards acids, e.g. cyanides of  $\text{Au}$ ,  $\text{Hg}$ , and  $\text{Ag}$ . Hot conc.  $\text{H}_2\text{SO}_4$  decomposes all cyanides, some easily, others slowly; the products are sulphate and  $\text{HCN}$  or  $\text{CO}$  and  $\text{NH}_3$ . Alkali cyanides are unchanged by heat alone; cyanides of the heavy metals are decomposed by heat, generally forming metal and  $\text{Cy}$ , sometimes  $\text{N}$  is evolved and  $\text{C}$  deposited on the metal, or a carbide of the metal is formed. Water decomposes cyanides at high temperatures ( $250^\circ$ – $800^\circ$ ), giving  $(\text{NH}_4)_2\text{CO}_3$  and  $\text{HCO}_2\text{NH}_2$  with metallic oxide, or sometimes metal and  $(\text{NH}_4)_2\text{CO}_3$ . Chlorine decomposes most cyanides generally forming metallic chloride and  $\text{CyCl}$ . Boiling with water and excess of  $\text{HgO}$  decomposes all cyanides, except platino-cyanides, with formation of  $\text{HgCy}_2$  and oxide of the metal of the cyanide.

Many cyanides form double salts, generally with haloid metallic compounds.

Very many cyanides combine with other cyanides to form double cyanides. These double cyanides are divisible into two classes, according as they are, or are not, decomposed by solutions of mineral acids with evolution of  $\text{HCN}$ . Silver potassium cyanide,  $\text{AgKCy}_2$ , for instance, reacts with dilute  $\text{HNO}_3\text{aq}$  to give  $\text{AgCy}$ ,  $\text{KNO}_3$ , and  $\text{HCN}$ , and with dilute  $\text{HClaq}$  it gives  $\text{AgCl}$ ,  $\text{KCl}$ , and  $\text{HCN}$ ; potassium ferrocyanide,  $\text{K}_4\text{FeCy}_6$ , on the other hand, reacts with  $\text{HClaq}$  to give ferrocyanic acid  $\text{H}_4\text{FeCy}_6$ . The members of the second class of double cyanides are generally regarded as metallic derivatives of acids which are themselves composed of  $\text{H}$  united with a metal and the radicle cyanogen, the metal and cyanogen together forming the negative radicle of the acid; thus, *ferrocyanic acid*  $\text{H}_4\text{FeCy}_6$  (better called *ferrocyanhydric acid*) forms a series of well-marked stable metallic derivatives which are obtainable from the acid by reactions similar to those whereby salts are produced from  $\text{HNO}_3$ ,  $\text{H}_2\text{SO}_4$ ,  $\text{H}_3\text{PO}_4$ , &c.

*Manganocyanic acid* (or *manganocyanhydric acid*)  $\text{H}_4\text{MnCy}_6$ , *cobaltcyanic acid* (or *cobaltcyanhydric acid*)  $\text{H}_4\text{CoCy}_6$ , *aurocyanic acid* (or *aurocyanhydric acid*)  $\text{HAuCy}_6$ , *platincyanic acid* (or *platincyanhydric acid*)  $\text{H}_4\text{PtCy}_6$ , and some other acids the negative radicles of which are composed of metal combined with cyanogen, have been isolated. Some of these metallic-cyanogen acids form derivatives in which part of the negative radicle is replaced by a negative

group, e.g.  $\text{H}_4\text{FeCy}_6\text{NO}$ . A few metallic-halogen acids are known, more or less analogous to the metallic-cyanogen acids, e.g.  $\text{H.AuCl}_4$ ,  $\text{H}_2\text{HgCl}_4$ ,  $\text{H}_2\text{PtCl}_6$ ; but the metallic-cyanogen acids are more numerous, and form many more stable salts than the metallic-halogen acids. The negative character of the radicle  $\text{CN}$  is well seen in the production of the numerous ferrocyanides, manganocyanides, platino-cyanides, &c. The affinities of a few metallic-cyanogen acids have been determined (v. e.g., p. 333); they seem to be very strong acids; on the other hand cyanhydric acid  $\text{N.CH}$  is an extremely weak acid (v. *CYANHYDRIC ACID*, p. 301); but sulphocyanic acid,  $\text{N.CSH}$ , has a very large affinity (v. *SULPHOCYANIC ACID*, p. 303).

It would be possible, and for some reasons advantageous, to divide the metallic cyanides into two main classes; class I. would include those cyanides which are decomposed by dilute mineral acids with evolution of  $\text{HCN}$ , and are therefore to be regarded as derivatives of  $\text{HCN}$ , and also those which although not yielding  $\text{HCN}$  by reactions with dilute acids must nevertheless, on account of their composition and modes of preparation, be regarded as derived from  $\text{HCN}$  (e.g.  $\text{HgCy}_2$ ); class II. would include those cyanides which yield metallic-cyanogen acids or are derived from such acids. The first class would contain all the simple, and many double, cyanides. Some double cyanides would hardly fall into either class;  $\text{HgCy}_2.2\text{KCy}$  for instance reacts with solutions of salts of  $\text{Zn}$ ,  $\text{Cd}$ ,  $\text{Pb}$ , &c., to form salts of the general form  $\text{HgCy}_2.\text{MCy}_2$  ( $\text{M} = \text{Zn}$ ,  $\text{Pb}$ ,  $\text{Cd}$ , &c.), hence  $\text{HgCy}_2.2\text{KCy}$  seems to be the  $\text{K}$  salt of the hypothetical acid  $\text{H}_2\text{HgCy}_4$ . The metallic-cyanogen acids which have been isolated are  $\text{H}_2\text{CrCy}_4$  (salts of  $\text{H}_2\text{CrCy}_4$  are also known),  $\text{H}_2\text{CoCy}_4$ ,  $\text{H}_2\text{CoCy}_4$ ,  $\text{H}_2\text{AuCy}_4$ ,  $\text{H}_2\text{IrCy}_4$ ,  $\text{H}_2\text{FeCy}_4$ ,  $\text{H}_2\text{FeCy}_4$ ,  $\text{H}_2\text{MnCy}_4$ ,  $\text{H}_2\text{OsCy}_4$ , salts of  $\text{H}_2\text{PtCy}_4$ ,  $\text{H}_2\text{PtCy}_4\text{Cl}$  (or  $\text{Br}$ ), salts of  $\text{H}_2\text{RhCy}_4$ ,  $\text{H}_2\text{RuCy}_4$ ; salts of the hypothetical  $\text{H}_2\text{PdCy}_4$  are also known, but they react more like double cyanides. No nickel- or nickeli-cyanides are known corresponding to  $\text{M}_2\text{CoCy}_4$  and  $\text{M}_2\text{CoCy}_4$ ;  $\text{Ni}$  double cyanides are easily decomposed by dilute acids with evolution of  $\text{HCy}$ , and are therefore to be classed with the less stable double cyanides.

Those cyanides, simple or double, which are readily decomposed by dilute acids with formation of  $\text{HCy}$  are poisonous; the stable salts of metallic-cyanogen acids, e.g.  $\text{K}_4\text{FeCy}_6$ , are not poisonous.

In this article the cyanides will be described in alphabetical order; the descriptions of the various compounds will show to which of the two main classes of cyanides they belong.

This article also includes descriptions of the *sulphocyanides* and the *selenocyanides*.

**SELENOCYANIDES.** These compounds are derived from *selenocyanhydric acid*  $\text{HSeCN}$ . The acid itself is only known in aqueous solution; it is very easily decomposed to  $\text{HCN}$  and  $\text{Se}$ ; the  $\text{K}$  salt is obtained by dissolving  $\text{Se}$  in  $\text{KCNaq}$ . (For individual selenocyanides, v. p. 348).

**SULPHOCYANIDES.** *Metallic derivatives of sulphocyanic* (or *thiocyanic*) *acid*. Sulphocyanic acid almost certainly has the constitution  $\text{HS.CN}$ ; while the replaceable  $\text{H}$  of cyanic acid is probably in direct union with  $\text{N}$ . The metallic sul-

phocyanides are not strictly comparable with the metallic cyanates; for this reason it seems better to use the name *sulphocyanides* rather than *sulpho-* (or *thio-*) *cyanates*. Cyanhydric acid is an extremely weak acid, but the affinity of sulphocyanic acid is nearly equal to that of hydrochloric (v. Ostwald's *Lehrbuch der allgemeinen Chemie*, 2, 849).

The general formulæ expressing the composition of sulphocyanides are  $\text{NCS.M}$ ,  $(\text{NCS})_n\text{M}^{1/n}$ ,  $(\text{NCS})_n\text{M}^{1/n}$ , &c. These salts are sometimes called *rhodanides*, a name first given to them by Berzelius because of the red colour which they give with ferric salts (p. 450).

Sulphocyanide of K is formed by direct addition of S to KCN; Na SCN is produced by passing CS<sub>2</sub> over heated NaNH<sub>2</sub> ( $\text{NaNH}_2 + \text{CS}_2 = \text{NCS.Na} + \text{H}_2\text{S}$ ); NH<sub>4</sub>SCN may be obtained by adding  $(\text{NH}_4)_2\text{S}_2$  to NCH<sub>3</sub>Aq, or by heating CS<sub>2</sub> with alcoholic NH<sub>3</sub> ( $\text{CS}_2 + 4\text{NH}_3 = \text{NCS.NH}_4 + (\text{NH}_4)_2\text{S}$ ); the sulphocyanides of the heavy metals are usually formed by double decomposition from the alkali sulphocyanides.

Most sulphocyanides are soluble in water; the salts of Cu, Pb, Hg, and Ag are insoluble. Dry alkali sulphocyanides may be heated in absence of air without change; in presence of air SO<sub>2</sub> is evolved and sulphate and cyanate are produced. Sulphocyanides of the heavy metals are decomposed by heat, generally giving S, CS<sub>2</sub>, metallic sulphide, and *mellon* (q. v. p. 323), on strongly heating the mellon yields Cy and N. The insoluble sulphocyanides are completely decomposed by H<sub>2</sub>S. Sulphocyanides of P and Si, P(SCy)<sub>3</sub>, and Si(SCy)<sub>4</sub>, respectively, are described under PHOSPHORUS and SILICON.

Many double sulphocyanides are known; most of these react as double salts, but some as metallic derivatives of acids composed of H united with a negative radicle which is itself composed of metal and sulphocyanogen (SCN). For instance *chromsulphocyanic* (or *chromsulphocyanhydric acid*)  $\text{H.Cr(SCN)}_3$  is known in aqueous solution, and many salts of this acid have been isolated. The acid  $\text{H}_2\text{Pt(SCN)}_4$  is also known in aqueous solution. (For individual sulphocyanides v. p. 348 *et seq.*)

#### Analysis of cyanides and sulphocyanides.

I. Alkali cyanides are estimated by ppn. with AgNO<sub>3</sub>Aq, or by Liebig's volumetric method (v. CYANHYDRIC ACID).

II. Many cyanides, including the double compounds of NCK with CuCy<sub>2</sub>, NiCy<sub>2</sub>, and ZnCy<sub>2</sub>, may be estimated by heating for some time with AgNO<sub>3</sub>, then adding HNO<sub>3</sub>Aq, and heating again; the AgCN formed is collected and weighed. According to Weith (*Fr.* 9, 379) K<sub>2</sub>FeCy<sub>4</sub>, K<sub>2</sub>CoCy<sub>4</sub>, and Prussian blue, may be wholly decomposed by heating for several hours in a closed tube with ammoniacal AgNO<sub>3</sub>; oxide of the heavy metal is ppd. while NH<sub>4</sub>Cy goes into solution; filtering and adding HNO<sub>3</sub>Aq ppt. AgCy.

III. Mercuric cyanide may be analysed by heating with ammoniacal Zn(NO<sub>3</sub>)<sub>2</sub>, whereby ZnCy<sub>2</sub> is formed (v. Rose a. Finkener, *Fr.* 1, 288).

IV. Many cyanides may be analysed by long boiling with HgO and water, filtering and determining Cy by boiling with ammoniacal Zn(NO<sub>3</sub>)<sub>2</sub>.

V. The metal in most cyanides may be determined by continued heating with conc. H<sub>2</sub>SO<sub>4</sub>,

vapourising excess of acid, and estimating the metal in the remaining sulphate by one of the usual methods.

VI. Soluble sulphocyanides may be analysed volumetrically by means of standard Ag solution in the same way as chlorides (Volhard, *Fr.* 1874 242).

#### CYANIDES.

Aluminium cyanide. Not isolated. A double Al-Fe cyanide is described by Tissier (*J. Ph.* 35, 88) as obtained by boiling K<sub>2</sub>FeCy<sub>4</sub>Aq with excess of an acid solution of a salt of Al; the composition of the pp. is approximately 3FeCy<sub>2</sub>.2AlCl<sub>3</sub>.

Ammonium cyanide NH<sub>4</sub>CN. Formed by passing NH<sub>3</sub> over red-hot coal (Kuhlman, *A.* 38, 62; Clouet, *A. Ch.* 11, 30; Langlois, *A.* 38, 64); also by passing CO and NH<sub>3</sub> over heated Pt black (K, *l.c.*). Prepared by heating together 3 parts dry K<sub>2</sub>FeCy<sub>4</sub> with 2 parts NH<sub>4</sub>Cl at 100° and leading the vapour into a well-cooled receiver (Bineau, *A. Ch.* 70, 263). Crystallises in cubes; volatilises at c. 36° with dissociation into HCN + NH<sub>3</sub> (Bineau, *l.c.*; Deville a. Troost, *C. R.* 56, 891). Vapour is inflammable in the air. Very poisonous. Easily decomposes in the air to a brownish mass. Easily soluble in water and alcohol. Berthelot (*C. R.* 91, 82) gives the following thermal data:— $[\text{C}, \text{N}_2, \text{H}] = 3,200$  (formation of solid NH<sub>4</sub>CN);  $[\text{N}, \text{CN}, \text{H}] = 40,500$  (solid NH<sub>4</sub>CN);  $[\text{HCN}, \text{NH}_3] = 20,500$  (solid NH<sub>4</sub>CN from gaseous materials);  $[\text{HCNAq}, \text{NH}_4\text{Ag}] = 1,300$ ;  $[\text{NH}_4\text{CN}, \text{Ag}] = -4,400$ .

Barium cyanide Ba(CN)<sub>2</sub>. Prepared by heating Ba<sub>2</sub>Fe(CN)<sub>6</sub> and extracting with water (Schulz, *J. pr.* 68, 257). The hydrate Ba(CN)<sub>2</sub>.H<sub>2</sub>O may be prepared by bringing HCN gas into contact with hydrated BaO (for details v. Joannis, *A. Ch.* [5] 27, 489). It is also formed when air is passed over a red-hot mixture of BaO and C (Marguerite a. Sourdeval, *C. R.* 50, 1100). Crystalline; quickly absorbs CO<sub>2</sub> from air; sl. sol. in water; heated to 300° in steam evolves NH<sub>3</sub>. When HCN is passed into BaO in CH<sub>3</sub>OH, a crystalline powder is formed of the composition Ba.CN.OCH<sub>3</sub> + CH<sub>3</sub>.OH, and when this is strongly heated *barium oxycyanide* BaCy<sub>2</sub>.BaO is formed (Drechsel a. Krüger, *J. pr.* [2] 21, 77). Joannis (*l.c.*) gives the following thermal data:— $[\text{BaOAg}, 2\text{HCNAq}] = 6,840$ ;  $[\text{BaCy}_2, \text{Ag}] = 1,780$ . Weselsky (*Z.* [2] 7, 61) prepares various double cyanides containing barium cyanide by passing HCN gas into a mixture of BaCO<sub>3</sub> with a salt of the other metal; e.g. using PtCl<sub>4</sub>Aq and BaCO<sub>3</sub>, the double cyanide BaCy<sub>2</sub>.PtCy<sub>2</sub> is obtained. The following double cyanides were produced:  $[\text{M} + \text{BaCy}_2] \cdot 2\text{M} \cdot 3\text{CdCy}_2 \cdot 10\text{H}_2\text{O}$ ;  $\text{M.Cu.Cy}_2 \cdot \text{H}_2\text{O}$ ;  $\text{M.NiCy}_2 \cdot 3\text{H}_2\text{O}$ ;  $\text{M.PdCy}_2 \cdot 4\text{H}_2\text{O}$ ;  $\text{M} \cdot 2\text{AgCy}_2 \cdot \text{H}_2\text{O}$ ;  $\text{M} \cdot \text{ZnCy}_2 \cdot 2\text{H}_2\text{O}$ .

Cadmium cyanide CdCy<sub>2</sub>. Obtained by dissolving freshly ppd. CdO.M<sub>2</sub>O in HCN<sub>2</sub>Aq, filtering from oxycyanide, and crystallising (Rammelsberg, *P.* 38, 364). Small white crystals; unchanged in air; decomposes above 200° in air. S. c. 1.7 in cold water. H.F.  $[\text{Cd}, \text{Cy}_2, \text{Ag}] = 33,960$ ;  $[\text{CdO.H}_2, 2\text{HCNAq}] = 13,700$  (*Th.* 3, 474).

Cadmium oxycyanide. By digesting CdO.M<sub>2</sub>O in HCN<sub>2</sub>Aq; the residue insol. in the acid is said to have the composition CdCy<sub>2</sub>.CdO.5H<sub>2</sub>O (Joannis, *C. R.* 93, 271).

Double cyanides containing cad.

mium cyanide. The salt  $\text{CdCy}_2 \cdot 2\text{KC}_2\text{O}_4$  is produced by adding  $\text{KC}_2\text{O}_4$  to solution of Cd acetate, evaporating, and crystallising. White octahedra; v. sol. water; unchanged in air at c.  $200^\circ$ . H.F.  $[\text{Cd}, \text{Cy}^2, 2\text{KC}_2\text{O}_4] = 44,750$ ;  $[\text{CdCy}_2\text{Aq}, 2\text{KC}_2\text{O}_4] = 10,790$  (*Th.* 3, 474). Solution gives pps. with various metallic salts, e.g. with solution of salts of Ca, Ba, Cu, Mn, Sr, Zn (Rammelsberg, P. 38, 364). The double salt  $2\text{CdCy}_2 \cdot \text{Cu}_2\text{Cy}_2$  is said to be formed by dissolving  $\text{CdO} \cdot \text{H}_2$  along with  $\text{CuCO}_3$  in  $\text{HCyAq}$ , and evaporating (Schuler, A. 87, 48). By dissolving  $\text{CdO} \cdot \text{H}_2$  and  $\text{CuO} \cdot \text{H}_2$  in  $\text{HCyAq}$  and allowing the liquid to evaporate in the air, the salt  $2\text{CdCy}_2 \cdot \text{Cu}_2\text{Cy}_2$  is obtained (Schuler, l.c.). Various other double salts are described by Schuler (l.c.).

**Calcium cyanide**  $\text{Ca}(\text{CN})_2$ . By heating  $\text{Ca}_2\text{FeCy}_2$  (Schulz, J. pr. 68, 257). A solution of  $\text{CaCy}_2$  is obtained by adding  $\text{HCyAq}$  to  $\text{CaCO}_3$ ; the solution soon decomposes; if conc., crystals of an oxycyanide separate,  $3\text{CaO} \cdot \text{CaCy}_2 \cdot 15\text{H}_2\text{O}$  (Joannis, C. R. 92, 1338, 1417). H.F.  $[\text{CaO}_2\text{Aq}, 2\text{HCyAq}] = 6,440$ ;  $[\text{Ca}_2\text{Cy}_2\text{Aq}] = 115,340$  (Joannis, A. Ch. [6] 27, 489).

**Cerium cyanide**, not isolated.  $\text{KC}_2\text{O}_4$  added to salts of Ce ppts. a white solid which at once decomposes with evolution of  $\text{HCN}$ , leaving Ce oxide (Beringer, A. 42, 139).

**Chromium cyanides**. Simple cyanides have not been isolated; the pps. obtained by adding  $\text{KC}_2\text{O}_4$  to  $\text{CrCl}_3\text{Aq}$  and  $\text{CrCl}_3\text{Aq}$  soon decompose.

**Potassium chromocyanide**  $\text{K}_2\text{CrCy}_2$ .  $\text{CrCO}_3$  (obtained by adding  $\text{K}_2\text{CO}_3\text{Aq}$  to  $\text{CrCl}_3\text{Aq}$  saturated with  $\text{CO}$ , air being excluded) is mixed with  $\text{KC}_2\text{O}_4$  until the solid has partially dissolved, the yellow liquid is filtered and evaporated (Moissan, A. Ch. [6] 4, 136). Long yellow needles; S.G. 1.71; S. ( $20^\circ$ ) 32-33; insol. alcohol, ether, benzene, and chloroform. Unchanged in air at ordinary temperature. Non-poisonous. Aqueous solution partially decomposed on boiling. Oxidising agents form chromicyanide,  $\text{K}_2\text{CrCy}_2$ ; with  $\text{FeSO}_4\text{Aq}$  gives red colouration, part of the salt in a solution may be thus detected (Moissan, l.c.). Gives pps. with metallic salts (v. also Christensen, J. pr. [2] 31, 163).

**Potassium chromicyanide**  $\text{K}_2\text{CrCy}_2$ . Prepared by oxidising  $\text{K}_2\text{CrCy}_2$ ; or by heating  $\text{KC}_2\text{O}_4$  with Cr alum, or with Cr-K chloride, or by dissolving freshly pptd.  $\text{Cr}_2\text{O}_3 \cdot \text{H}_2$  in acetic acid, evaporating to dryness, dissolving in water, and adding the liquid to hot  $\text{KC}_2\text{O}_4$  (Kaiser, A. Supplbd. 3, 163; Stridsberg, J. 1864. 304; Descamps, A. Ch. [6] 24, 178; Christensen, J. pr. [2] 31, 163). Yellow monoclinic crystals; sol. water, insol. absolute alcohol; easily decomposed by dilute acids. Gives pps. with most metallic salts (v. Christensen, J. pr. [2] 23, 52).

**Ammonium chromicyanide**  $(\text{NH}_4)_2\text{CrCy}_2$  (Kaiser, A. Supplbd. 3, 163).

**Chromocyanhydric acid**  $\text{H}_2\text{CrCy}_2$  (chromocyanic acid). Small white crystals, obtained by decomposing the K salt by dilute  $\text{H}_2\text{SO}_4\text{Aq}$ ; sol. water, solution rapidly decomposes in air (Moissan, A. Ch. [6] 4, 136).

According to Descamps (A. Ch. [5] 24, 178) salts analogous to *nitroprussides* (q. v. p. 340) are produced by passing NO into chromocyanides.

**Cobalt cyanides**. One simple cyanide,  $\text{CoCy}_2$ , is known; two series of salts derived from cobalto-cyanhydric acid and cobalti-cyanhydric acid have been prepared; the cobalto-cyanides are very unstable, while the cobalti-cyanides are stable salts.

**Cobaltous cyanide**  $\text{Co}(\text{CN})_2$ . Buff-coloured pp. by adding  $\text{KC}_2\text{O}_4$  to Co salts, or  $\text{HCNAq}$  to Co acetate (Wöhler, *Gehlen's Journ.* 6, 234). The pp. contains  $2\text{H}_2\text{O}$  which it does not lose till c.  $280^\circ$  (Zwenger, A. 62, 157). Dissolves in  $\text{KC}_2\text{O}_4$  to form  $\text{K}_2\text{CoCy}_2$ , which quickly changes to  $\text{K}_2\text{CoCy}_4$ .

**Cobaltocyanhydric acid**  $\text{H}_2\text{CoCy}_2$  (Cobaltocyanic acid). Very unstable pp. obtained by decomposing Pb cobaltocyanide by  $\text{H}_2\text{S}$ , filtering, and adding alcohol (Descamps, *Bl.* [2] 31, 49).

**Potassium cobaltocyanide**  $\text{K}_2\text{CoCy}_2$ . Amethyst-coloured, deliquescent needles; obtained by adding alcohol to a cold solution of  $\text{CoCy}_2$  in a slight excess of conc.  $\text{KC}_2\text{O}_4\text{Aq}$ . Very unstable: easily changes to  $\text{K}_2\text{CoCy}_4$ . Insol. alcohol and ether. Solution gives pps. with many metallic salts; these are probably cobaltocyanides (Descamps, l.c.). According to Descamps (A. Ch. [5] 24, 178) salts analogous to the *nitroprussides* (q. v. p. 340) are obtained by passing NO into cobaltocyanides.

**Cobalticcyanhydric acid**  $\text{H}_2\text{CoCy}_2 \cdot 2\text{H}_2\text{O}$  (Cobalticcyanic acid). Obtained by evaporating the K salt in solution with conc.  $\text{H}_2\text{SO}_4$ , and extracting the residue with alcohol (Zwenger, A. 62, 157); or by decomposing the Cu salt by  $\text{H}_2\text{S}$ . Colourless needles; v. e. sol. in water and alcohol; insol. dry ether. Very acid taste. Not decomposed by heating with conc.  $\text{HClAq}$  or  $\text{HNO}_3\text{Aq}$ , but slowly by hot conc.  $\text{H}_2\text{SO}_4$ , giving sulphates of NH<sub>4</sub> and Co, and evolving  $\text{SO}_2$ , CO, and  $\text{CO}_2$ .

**Potassium cobalticcyanide**  $\text{K}_2\text{CoCy}_2$ . Obtained by dissolving  $\text{CoCy}_2$  or  $\text{Co}_2\text{O}_3$  in  $\text{KC}_2\text{O}_4\text{Aq}$ , evaporating, and crystallising (Zwenger, A. 62, 157).  $\text{KC}_2\text{O}_4$  and  $\text{K}_2\text{CO}_3$  may be removed by decomposing by acetic acid and prg. by alcohol. Slightly yellow, transparent, rhombic crystals; isomorphous with  $\text{K}_2\text{FeCy}_2$ . B. sol. water, insol. alcohol. S.G. 1.906. Decomposed by strong acids with separation of cobalticcyanhydric acid  $\text{H}_2\text{CoCy}_2$ ; not decomposed at ordinary temperatures by  $\text{HClAq}$  or  $\text{HNO}_3\text{Aq}$ . Reduced by Bismalgam to  $\text{K}_2\text{CoCy}_4$ .

**Cobalticcyanides**. Besides the K salt the following have been isolated ( $\text{X} = \text{CoCy}_2$ ):—

$(\text{NH}_4)_2\text{X} \cdot \text{H}_2\text{O}$  (Zwenger, A. 62, 157).  
 $[\text{N}(\text{CH}_3)_3]_2\text{X}$  (Claus a. Merck, B. 16, 2737).  
 $\text{Ba}_2\text{X} \cdot 22\text{H}_2\text{O}$  (Z., l.c.);  $\text{BaNH}_4\text{X} \cdot \text{H}_2\text{O}$ ;  
 $\text{BaKX} \cdot 11\text{H}_2\text{O}$ ;  $\text{BaLiX} \cdot 15\text{H}_2\text{O}$ ;  $\text{Ba}_2\text{X} \cdot \text{BaO} \cdot \text{H}_2$ ;  
 $\text{Ba}_2\text{X} \cdot \text{BaCl}_2 \cdot 6\text{H}_2\text{O}$  (Weselsky, B. 2, 588).  
 $\text{CaNH}_4\text{X} \cdot 10\text{H}_2\text{O}$ ;  $\text{CaKX} \cdot 9\text{H}_2\text{O}$  (W., l.c.).  
 $\text{CrX} \cdot 5\text{NH}_4 \cdot 1\frac{1}{2}\text{H}_2\text{O}$  (Christensen, J. pr. [2] 23, 52);  $\text{CrX} \cdot 6\text{NH}_4$  (Braun, A. 125, 153, 197).  
 $\text{Co}_2\text{X} \cdot 14\text{H}_2\text{O}$  (Z., l.c.);  $\text{Co}_2\text{X} \cdot 5\text{NH}_4 \cdot 1\frac{1}{2}\text{H}_2\text{O}$  (Gibbs a. Genth, A. 104, 150, 295; Braun, l.c.);  
 $\text{CoX} \cdot 6\text{NH}_4 \cdot \frac{1}{2}\text{H}_2\text{O}$  (G. a. G., l.c.).  $\text{Cu}_2\text{X} \cdot 7\text{H}_2\text{O}$ ;  
 $\text{Cu}_2\text{X} \cdot 4\text{NH}_4 \cdot 10\text{H}_2\text{O}$  (Z., l.c.).  $\text{Pb}_2\text{X} \cdot 7\text{H}_2\text{O}$  (Z., l.c.);  $\text{Pb}_2\text{X} \cdot 6\text{PbO} \cdot 3\text{H}_2\text{O}$  (Z., l.c.);  
 $\text{Pb}_2\text{X} \cdot 3\text{PbO} \cdot \text{H}_2 \cdot 11\text{H}_2\text{O}$ ;  $\text{Pb}_2\text{X} \cdot \text{Pb}(\text{NO}_3)_2 \cdot 12\text{H}_2\text{O}$ ;  
 $\text{PbKX} \cdot 3\text{H}_2\text{O}$ ;  $\text{Pb}(\text{NH}_4)_2\text{X} \cdot 3\text{H}_2\text{O}$  (Schuler, W. A. B. 1879 [n]. 802);  $\text{Ni}_2\text{X} \cdot 12\text{H}_2\text{O}$ ;  
 $\text{Ni}_2\text{X} \cdot 4\text{H}_2\text{O} \cdot 0.7\text{H}_2\text{O}$  (Z., l.c.).  $\text{Na}_2\text{X} \cdot 2\text{H}_2\text{O}$  (Z., l.c.);

$\text{Na}(\text{NH}_4)_2\text{X}$  (Weselsky, B. 2, 588).  $\text{Ag}_2\text{X} \cdot \text{NH}_4 \cdot 3\text{H}_2\text{O}$  (Z., l.c.).  $\text{Sr} \cdot 2\text{X} \cdot 20\text{H}_2\text{O}$ ;  $\text{Sr}(\text{NH}_4)_2 \cdot \text{X} \cdot 10\text{H}_2\text{O}$ ;  $\text{Sr} \cdot \text{KX} \cdot 9\text{H}_2\text{O}$  (W., l.c.).  $\text{Ti}_2\text{X}$  (Fron-Müller, B. 11, 91).  $\text{YX} \cdot 2\text{H}_2\text{O}$  (Cløve a. Høglund, Bl. [2] 18, 197).

A fairly general method of preparing cobalt-cyanides consists in first preparing the barium salt  $\text{Ba}_2(\text{CoCy}_2)_x \cdot x\text{H}_2\text{O}$ , decomposing a solution of this by the sulphates of other metals, filtering, and crystallising; the Ba salt is most easily produced by passing HCy gas into a mixture of  $\text{CoSO}_4$  and  $\text{BaCO}_3$ , filtering, and crystallising (Weselsky, W. A. B. [9], 261). Cobaltcyanides containing two metals, e.g.  $(\text{NH}_4)_2\text{Na} \cdot \text{CoCy}_2$ ,  $\text{BaK} \cdot \text{CoCy}_2$ , are obtained by mixing solutions of the cobaltcyanides, evaporating, and crystallising; these salts generally crystallise well (Weselsky, l.c.). Cobaltous cobaltcyanide  $\text{Co}_2(\text{CoCy}_2)_2 \cdot 14\text{H}_2\text{O}$  corresponds in composition to ferrous ferricyanide  $\text{Fe}_2(\text{FeCy}_2)_2$  (q. v. p. 338) or *Turnbull's blue*; it is a pale red amorphous solid; obtained either by adding  $\text{K}_2\text{CoCy}_2$  to  $\text{CoSO}_4$  and washing thoroughly with water, or by heating  $\text{H}_2\text{CoCy}_2$  with conc.  $\text{H}_2\text{SO}_4$ , and adding water before decomposition is complete. This salt loses part of its water at  $100^\circ$ , and turns blue. It is insol. water; decomposed by KOHAq with separation of  $\text{CoO} \cdot x\text{H}_2\text{O}$ . Dry  $\text{Co}_2(\text{CoCy}_2)_2$  is blue; it combines with water with production of much heat (Zwengler, A. 62, 172).

**Copper cyanides.** Three cyanides of Cu are known, cuprous cyanide, cupric cyanide, and cupro-cupric cyanide; the first-named is the most stable; double compounds of each, especially with  $\text{NH}_3$ , have been isolated.

**Cuprous cyanide**  $\text{Cu}_2\text{Cy}_2$ . Formed by adding  $\text{KCyaq}$  to  $\text{CuCl}$ , dissolved in  $\text{HClAq}$ , or to  $\text{CuSO}_4\text{Aq}$  reduced by  $\text{SO}_2$ ; also by the action of  $\text{HCNAq}$  on freshly pptd.  $\text{Cu}(\text{OH})_2$  (Rammelsberg, P. 42, 131; 85, 145). Prepared, as small lustrous monoclinic crystals, by decomposing  $\text{Cu}_2\text{Cy}_2 \cdot \text{PbCy}_2$  suspended in water by  $\text{H}_2\text{S}$ , filtering, and allowing the filtrate (which probably contains  $\text{H}_2\text{Cu}_2\text{Cy}_2$ ) to evaporate (Dauber, A. 74, 206; Wöhler, A. 78, 370); the salt  $\text{Cu}_2\text{Cy}_2 \cdot \text{PbCy}_2$  is obtained by adding a Pb salt to the solution of  $\text{Cu}_2\text{Cy}_2 \cdot \text{KCya}$ , formed by dissolving  $\text{Cu}(\text{OH})_2$  in  $\text{KCyaq}$ . Insol. water; sol.  $\text{HClAq}$ ,  $\text{NH}_4\text{Aq}$ , and solutions of  $\text{NH}_4$  salts (Pagenstecher, N. J. T. [3] 1, 451); pptd. by  $\text{H}_2\text{O}$  from solution in  $\text{HClAq}$ ; decomposed by conc.  $\text{HNO}_3\text{Aq}$ , not by dilute  $\text{H}_2\text{SO}_4\text{Aq}$ . Dissolves in alkali cyanides to form double salts, from which it is pptd. by  $\text{HClAq}$ .

**Double cyanides containing cuprous cyanide** (sometimes called *cuprosocyanides*):—1. With  $\text{NH}_4\text{CN}$ , forming monoclinic prisms, insol.  $\text{H}_2\text{O}$ — $\text{Cu}_2\text{Cy}_2 \cdot \text{NH}_4\text{Cy}$  (Lallemand, C. R. 60, 1142);  $\text{Cu}_2\text{Cy}_2 \cdot 2\text{NH}_4\text{Cy}$  (Dufau, C. R. 36, 1099).—2. With  $\text{KCN}$ — $\text{Cu}_2\text{Cy}_2 \cdot \text{KCN} \cdot \text{H}_2\text{O}$  (Schiff a. Becchi, A. 138, 24);  $\text{Cu}_2\text{Cy}_2 \cdot 2\text{KCN}$ ;  $\text{Cu}_2\text{Cy}_2 \cdot 6\text{KCN}$  (Rammelsberg, P. 42, 114; 106, 491);  $8\text{Cu}_2\text{Cy}_2 \cdot 4\text{KCN}$  (Rammelsberg, P. 73, 117). The salt  $\text{Cu}_2\text{Cy}_2 \cdot \text{KCN} \cdot \text{H}_2\text{O}$  is insol. in  $\text{H}_2\text{O}$ , the others are soluble; the soluble salts give pps. with salts of the heavy metals; e.g. with salts of Fe, Pb, Mn. The pps. thus obtained may be regarded as *cuprosocyanides* of iron, &c. Many of the double cyanides containing  $\text{Cu}_2\text{Cy}_2$ , are sometimes called *cuprosocyanides*, and are regarded as salts of the hypothetical cuprosocyanhydric acid  $\text{H}_2\text{Cu}_2\text{Cy}_2$ ; e.g.  $\text{Cu}_2\text{Cy}_2 \cdot 2\text{NH}_4\text{Cy}$  is

often formulated as  $(\text{NH}_4)_2\text{Cu}_2\text{Cy}_2$ , and is called *ammonium cuprosocyanide*. The chief objection to this view is that the so-called cuprosocyanides are easily decomposed by dilute acids with precipitation of  $\text{Cu}_2\text{Cy}_2$  and evolution of  $\text{HCy}$ ; hence it seems better to class them with the double cyanides (e.g. of Ni) than with the salts of acids the negative radicals of which are composed of metal and cyanogen.—3. With other cyanides— $\text{Cu}_2\text{Cy}_2 \cdot \text{BaCy}_2 \cdot \text{H}_2\text{O}$  (Meillet, J. Ph. [3] 3, 413; Weselsky, B. 2, 588);  $\text{Cu}_2\text{Cy}_2 \cdot 2\text{CdCy}_2$  (Schüler, A. 87, 46); compounds with  $\text{NaCN}$  also exist, but their composition has not been accurately determined (v. Meillet, J. Ph. [3] 3, 413).

**Cupric cyanide**  $\text{CuCy}_2$ . This is probably the composition of the yellow pp. obtained by adding  $\text{KCyaq}$  to solutions of Cu salts; very unstable, decomposing at ordinary temperatures to  $\text{Cy}$  and  $\text{Cu}_2\text{Cy}_2 \cdot \text{CuCy}_2$  (Rammelsberg, P. 42, 131; 85, 145; Lallemand, C. R. 58, 750).

The double cyanide  $\text{CuCy}_2 \cdot 2\text{CdCy}_2$  is described by Schüler (A. 87, 46).

**Cupro-cupric cyanide**  $\text{CuCy}_2 \cdot \text{Cu}_2\text{Cy}_2 \cdot 5\text{H}_2\text{O}$ . Obtained by adding  $\text{KCyaq}$  to a Cu salt solution and allowing the pp. to remain exposed to the air, or by adding a solution of one of the K cuprous cyanides to a Cu salt (Hadow, C. J. 13, 106). Green lustrous crystals, decomposing at  $100^\circ$  to  $\text{Cu}_2\text{Cy}_2$  with evolution of  $\text{H}_2\text{O}$  and  $\text{Cy}$ . Acids evolve  $\text{HCy}$ , ppg.  $\text{Cu}_2\text{Cy}_2$ , and leaving a cupric salt in solution. The fact that this salt may be obtained by adding  $2\text{KCya} \cdot \text{Cu}_2\text{Cy}_2$  ( $\text{K}_2\text{Cu}_2\text{Cy}_2$ ) to solution of a Cu salt suggests that  $\text{CuCy}_2 \cdot \text{Cu}_2\text{Cy}_2$  may be the cupric salt of the hypothetical cuprosocyanhydric acid  $\text{H}_2\text{Cu}_2\text{Cy}_2$ ; if this view is adopted the salt in question would be formulated as  $\text{Cu}_2\text{Cu}_2\text{Cy}_2$ , and called *cupric cuprosocyanide*.

The compounds  $\text{CuCy}_2 \cdot \text{Cu}_2\text{Cy}_2 \cdot \text{H}_2\text{O}$  and  $\text{CuCy}_2 \cdot 2\text{Cu}_2\text{Cy}_2 \cdot \text{H}_2\text{O}$  have been described (Dufau, C. R. 36, 1099; Lallemand, C. R. 58, 750).

**Double compounds of cupro-cupric cyanide with ammonia.** The following have been isolated ( $\text{X} = \text{CuCy}_2 \cdot \text{Cu}_2\text{Cy}_2$ ):— $\text{X} \cdot 2\text{NH}_3 \cdot \text{H}_2\text{O}$ ;  $\text{X} \cdot \text{NH}_3$ ;  $\text{X} \cdot 6\text{NH}_3$  (Dufau, C. R. 36, 1099).  $\text{X} \cdot 3\text{NH}_3$  (Mills, Z. 1862, 545). Also  $\text{CuCy}_2 \cdot 2\text{Cu}_2\text{Cy}_2 \cdot \text{NH}_4 \cdot 2\text{H}_2\text{O}$  (Hilkenkamp, A. 97, 218). These ammoniacal compounds are sometimes looked on as salts of the hypothetical cuprosocyanhydric acid  $\text{H}_2\text{Cu}_2\text{Cy}_2$ ; they are supposed to be obtained by replacing H by complex radicals containing Cu derived from  $2\text{NH}_3$ . On this view the compounds in question may be formulated and named as follows:—

$(\text{N}_2\text{H}_4\text{Cu})_2\text{Cu}_2\text{Cy}_2$ , *cuprodiammonio-cuprosocyanide* ( $= \text{CuCy}_2 \cdot \text{Cu}_2\text{Cy}_2 \cdot 2\text{NH}_3$ ).

$(\text{N}_2\text{H}_4(\text{NH}_4))_2\text{Cu}_2\text{Cy}_2$ , *cuprotetrammonio-cuprosocyanide* ( $= \text{CuCy}_2 \cdot \text{Cu}_2\text{Cy}_2 \cdot 4\text{NH}_3$ ).

$(\text{N}_2\text{H}_4(\text{NH}_4))_3\text{Cu}_2\text{Cy}_2$ , *cuprohexammonio-cuprosocyanide* ( $= \text{CuCy}_2 \cdot \text{Cu}_2\text{Cy}_2 \cdot 6\text{NH}_3$ ).

**Gold cyanides.** Aurous cyanide  $\text{AuCy}$ , and several double cyanides of AuCy are known; also auricyanhydric acid  $\text{HAuCy}$ , and its salts.

**Aurous cyanide**  $\text{AuCy}$ . Prepared by evaporating  $\text{AuCy} \cdot \text{KCya}$  with  $\text{HClAq}$ , and washing the residue with water;  $\text{AuCy} \cdot \text{KCya}$  is obtained by dissolving finely divided Au or  $\text{Au}_2\text{O}$  in  $\text{KCyaq}$ .  $\text{AuCy}$  is also obtained by heating  $\text{Au}_2\text{O} \cdot 2\text{H}_2\text{O}$  with  $\text{HCNAq}$  (Himly, A. 42, 157, 337). Citron-yellow crystalline powder; insol. water, alcohol, or ether. Heated it gives Au and Cy. Not

acted on by hot  $\text{HClAq}$ ,  $\text{HNO}_3\text{Aq}$ , or  $\text{H}_2\text{SO}_4\text{Aq}$ ; slowly decomposed by *aqua regia*; not acted on by  $\text{H}_2\text{S}$ ; sol.  $(\text{NH}_4)_2\text{S}_2\text{Aq}$ , from which solution acids ppt.  $\text{Au}_2\text{S}_3$ . Decomposed by hot  $\text{KOHAc}$  to Au and a solution of  $\text{AuCy.KCy}$ . Sol. hot  $\text{NH}_4\text{Aq}$ , and in alkali thiosulphates.

Double cyanides containing aurous cyanide:  $\text{AuCy.KCy}$ ; obtained by dissolving  $\text{AuCy}$ ,  $\text{Au}_2\text{O}$ , or finely divided Au, in  $\text{KCyaq}$ , and evaporating (Himly, *A.* 42, 157, 337; Bagration, *J. pr.* 31, 367; Elsner, *J. pr.* 37, 333). Colourless, transparent, rhombic octahedra. E. sol. water, sl. sol. alcohol, insol. ether (Glassford a. Napier, *P. M.* [3] 25, 71). Decomposed by warming with acids, giving pp. of  $\text{AuCy}$ . Iodine dissolves in  $\text{AuCy.KCyAq}$ , when excess of I is added and the liquid cooled dark brownish violet crystals separate of  $\text{AuCy.KCy.I}_2$ ; analogous compounds are obtained by adding excess of Br or Cl to  $\text{AuCy.KCyAq}$ . These compounds may be regarded as K salts of the hypothetical iodo-, bromo-, and chloro-auricyanhydric acids  $\text{HAuCy.X}_2$  ( $\text{X} = \text{I, Br, or Cl}$ ) (v. Lindbom, *B.* 10, 1725; Blomstrand, *J. pr.* [2] 3, 213). The following double cyanides are also known; most of them combine with I, Br, and Cl;  $\text{AuCy.NH}_4\text{Cy}$  (Himly, *A.* 42, 157, 337; Lindbom, *B.* 10, 1725);  $2\text{AuCy.BaCy}_2.2\text{H}_2\text{O}$ ;  $2\text{AuCy.CaCy}_2.3\text{H}_2\text{O}$ ;  $2\text{AuCy.CdCy}_2$ ;  $2\text{AuCy.CoCy}_2$ ;  $\text{AuCy.NaCy}$ ;  $2\text{AuCy.SrCy}_2.3\text{H}_2\text{O}$ ;  $2\text{AuCy.ZnCy}_2$  (Lindbom, *B.* 10, 1725). A number of other double cyanides of Au are described by Lindbom (*Bl.* [2] 29, 116).

**Auricyanhydric acid**  $\text{HAuCy}.3\text{H}_2\text{O}$ . Large white tablets; obtained by ppg.  $\text{KAuCy}$ , by  $\text{AgNO}_3\text{Aq}$ , and decomposing the pp. by less than an equivalent quantity of cold  $\text{HClAq}$ . Sol. water, alcohol, and ether. Melts at  $50^\circ$ , decomposing at a higher temperature to  $\text{AuCy}$  and  $\text{HCy}$ , and then to Au and Cy. Solution gives  $\text{AuCy}$  on heating (v. Lindbom, *B.* 10, 1725).

**Auricyanides** (Himly, *A.* 42, 157, 337; Lindbom, *l.c.*).  $\text{NH}_4\text{AuCy}.3\text{H}_2\text{O}$ ,  $\text{KAuCy}.1\frac{1}{2}\text{H}_2\text{O}$ ; formed by adding perfectly neutral  $\text{AuCl}_3\text{Aq}$  to warm conc.  $\text{KCyaq}$ ; colourless tablets, v. sol. hot water, insol. absolute alcohol: loses all  $\text{H}_2\text{O}$  at  $200^\circ$ , and at the same time decomposes to  $\text{AuCy.KCy}$  and Cy.  $\text{AgAuCy}$ ; yellow pp. formed by adding  $\text{AgNO}_3\text{Aq}$  to  $\text{KAuCyAq}$ ; insol.  $\text{HNO}_3\text{Aq}$ ; sol.  $\text{NH}_4\text{Aq}$ .  $\text{Co(AuCy)}_2$ .

**Indium cyanide**. Pp. obtained by adding  $\text{KCyaq}$  to an In salt solution; sol. excess of  $\text{KCyaq}$ ; on evaporating this liquid all In is ppt. as hydroxide (Meyer, *J.* 1868, 244).

**Iridium cyanides**. The cyanide  $\text{IrCy}$ , is known; also iridium cyanhydric acid  $\text{H.IrCy}$ , and its salts (v. Martius, *A.* 117, 357; Claus, *J.* 1855, 444; Wöhler a. Booth, *P.* 31, 161; Rammeisberg, *P.* 42, 140).

**Iridium cyanide**  $\text{IrCy}_2$ . Green powder, obtained by decomposing  $\text{H}_2\text{IrCy}_6\text{Aq}$  by  $\text{HClAq}$ .

**Iridium cyanhydric acid**  $\text{H.IrCy}$ . Obtained by decomposing the Ba salt (q.v.) by  $\text{H}_2\text{SO}_4\text{Aq}$ , filtering and adding ether. Crystallises from ether in white crystalline crust; i.e. sol. alcohol and water. Decomposes at  $300^\circ$ , evolving  $\text{HCN}$ . Decomposed by  $\text{HClAq}$  giving pp. of  $\text{IrCy}_2$ .

**Iridicyanides**  $\text{K}_2\text{IrCy}_2$ ; obtained by fusing  $\text{IrCl}_3.2\text{NH}_4\text{Cl}$  with  $1\frac{1}{2}$  pts.  $\text{KCyaq}$  for 10–15 min., treating fused mass with water, filtering, and

crystallising. Very stable salt; crystallises in orthorhombic prisms; insol. alcohol (W. a. B.).

$\text{Ba}_2(\text{IrCy}_2)_2.18\text{H}_2\text{O}$ ; obtained by fusing  $\text{IrCl}_3.2\text{NH}_4\text{Cl}$  with  $1\frac{1}{2}$  pts.  $\text{KCyaq}$ ; allowing to cool, dissolving in water, adding  $\text{HClAq}$ , ppg. by addition of  $\text{CuSO}_4\text{Aq}$ , washing pp. and digesting it with excess of  $\text{BaO}_2\text{H}_2$ , passing  $\text{CO}$ , through the liquid, filtering and crystallising; the first crop of crystals generally contains Ba platino-cyanide, the second crop is free from this salt. Crystallises in prisms, which effloresce in air, losing  $12\text{H}_2\text{O}$ ; very stable salt.

A solution of  $\text{H}_2\text{IrCy}_2$  gives pps. with salts of many heavy metals.

**Iron cyanides**. No simple cyanide of Fe has been isolated with certainty. Addition of  $\text{KCyaq}$  to solution of a ferrous salt produces a yellow-red to brown-red pp., which is probably  $\text{FeCy}_2$ , but always contains K (Fresenius, *A.* 106, 210); when the ferrous salt is in slight excess the composition of the pp. approximates to  $\text{KFeCy}_2$  (Stadeler, *A.* 154, 1).  $\text{KCyaq}$  added to solution of a ferric salt ppts.  $\text{Fe}_2\text{O}_3\text{H}_2$  (Haidlen a. Fresenius, *A.* 42, 130). If iron cyanides exist they are very unstable. Very many compound cyanides of iron with other metals have been prepared; these belong to the class of stable compound cyanides which are not resolved by acids into their constituent cyanides; as a rule their reactions are similar to those of ordinary salts, e.g. cf. the reaction of  $\text{KFeCy}_2\text{Aq}$  with  $\text{CuSO}_4\text{Aq}$ , giving  $\text{CuFeCy}_2$  and  $\text{K}_2\text{SO}_4\text{Aq}$ , with that of  $\text{BaCl}_2\text{Aq}$  and  $\text{Na}_2\text{SO}_4\text{Aq}$ , giving  $\text{BaSO}_4$  and  $\text{NaClAq}$ . The compound cyanides of iron are generally more stable than their constituent cyanides. This is shown, among other ways, by looking at the thermal changes which accompany the production of these double cyanides. Thus, the heat of formation of solid  $\text{KFeCy}_2$  from  $4\text{K} + \text{Fe} + 6\text{Cy}$  is c. 367,000 (Berthelot, *C. R.* 91, 82), the heat of formation of  $4\text{KCy}$  (solid) from  $4\text{K} + 4\text{Cy}$  is c. 270,000. We have then

$$\begin{aligned} [\text{K}^+, \text{Fe}, \text{Cy}^*] &= 367,000 \\ [\text{K}^+, \text{Cy}^*] &= 270,000 \end{aligned}$$

hence  $[4\text{KCy}, \text{Fe}, \text{Cy}^*] = 97,000$

Now the heat of formation of a ferrous salt is generally somewhat less than that of the corresponding Zn salt; but  $[\text{Zn}, \text{Cy}^*] = \text{c. } 53,000$  (solid  $\text{ZnCy}$ ), therefore we may provisionally conclude that  $[\text{Fe}, \text{Cy}^*] = \text{c. } 50,000$ .

Now if  $[4\text{KCy}, \text{Fe}, \text{Cy}^*] = 97,000$  and  $[\text{Fe}, \text{Cy}^*] = 50,000$ , it follows that  $[4\text{KCy}, \text{FeCy}^*] = 47,000$ : that is the combination of  $4\text{KCy}$  with  $\text{FeCy}_2$  to produce  $\text{K}_2\text{FeCy}_2$  is accompanied by the production of a quantity of heat roughly equal to 47,000 gram-units. This quantity of heat is much larger than that generally produced in the formation of double salts; e.g.  $[\text{KCyaq}, \text{AgCy}] = 11,200$ ,  $[\text{HgCyAq}, 2\text{KCyaq}] = 12,000$ ,  $[\text{HgI}_2, 2\text{KI}] = 3,000$ ,  $[\text{ZnSO}_4, \text{K}_2\text{SO}_4] = 4,000$ . Hence on the thermal evidence alone we might provisionally conclude that  $\text{K}_2\text{FeCy}_2$  does not belong to the class of double salts.

In considering the compound cyanides of iron, it is advantageous to begin with the two typical salts, potassium ferrocyanide  $\text{K}_4\text{FeCy}_6$ , and potassium ferricyanide  $\text{K}_3\text{FeCy}_6$ .  $\text{K}_4\text{FeCy}_6$  is produced by the action of oxidisers on  $\text{KFeCy}_2$ , and reducing agents change  $\text{K}_3\text{FeCy}_6$  to  $\text{K}_4\text{FeCy}_6$ . To each of these salts there corresponds an acid,

$H_2FeCy_4$  and  $H_2FeCy_3$ , respectively. These acids have been isolated, and from each has been obtained a great many salts and double salts. Some of these salts form derivatives, e.g. the *nitroprussides*; and finally there are a few compound iron cyanides not belonging to either of the two main classes.

We shall consider first *ferrocyanhydric acid*  $H_2FeCy_4$ , and its salts, the *ferrocyanides*; then *ferricyanhydric acid*,  $H_2FeCy_3$ , and its salts, the *ferricyanides*; then the *nitroprussides*; and finally the *perferrocyanides*.

The ferro- and ferricyanides are described in alphabetical order; double salts are also described in alphabetical order, thus barium potassium ferrocyanide is described under barium ferrocyanides, but strontium-potassium ferrocyanide under potassium ferrocyanides.

FERROCYANHYDRIC ACID AND FERROCYNANIDES.

*Ferrocyanhydric acid*  $H_2FeCy_4$ . (*Ferrocyanic acid*. *Hydroferrocyanic acid*. *Ferroprussic acid*. *Hydrogen ferrocyanide*.) Discovered by Porret in 1814 (*T.* 1814. 527).

*Formation*.—1.  $Ba_2FeCy_4$  is decomposed by an equivalent of  $H_2SO_4$  (Porret, *l.c.*).—2.  $Cu_2FeCy_4$  or  $Pb_2FeCy_4$  is decomposed by  $H_2S$  (Berzelius, *S.* 30, 44).—3. Prussian blue is decomposed by conc.  $HClAq$ , the solution is separated from  $Fe_2O_3$ , and evaporated (Robiquet).

*Preparation*.—To a cold conc. aqueous solution of  $K_2FeCy_4$ , which has been boiled to expel air, is added a slight excess of cold conc. air-free  $HClAq$ ; ether is then added, whereby from 96 to 100 p.c. of the  $H_2FeCy_4$  produced is pptd.; the pp. is washed with  $HClAq$  and then with ether; it may be recrystallised by dissolving in alcohol and adding ether; all operations should be conducted as far as possible in absence of  $O$  (Poselt, *A.* 42, 163; v. also Liebig, *A.* 87, 127; Dolfus, *A.* 65, 221).

*Properties and Reactions*.—White crystalline powder; becomes blue in moist air, with evolution of  $HCN$  and production of Prussian blue,  $Fe_3Cy_4$ , (Heimann a. Carius, *A.* 113, 39). Unchanged in sunlight in an atmosphere of  $H_2$ . Soluble in water; solution is strongly acid to litmus; it decomposes carbonates, acetates, tartrates, and oxalates.  $H_2FeCy_4$  is a strong acid; relative affinity not very much less than that of  $HCl$  (v. Ostwald's *Lehrbuch*, 2, 851). When boiled with water is decomposed to  $HCN$  and white  $FeH_2(FeCy_4)$  (R. a. C., *l.c.*). Berthelot (*C. R.* 91, 82) gives  $H.F.$  of the acid in solution as  $(H_2Fe_4CN_4Aq) = 107.200$ ; and the heat of neutralisation (*C. R.* 78, 1085) as  $(H_2FeCy_4Aq, 4KOH) = 54.000$ . Ferrocyanhydric acid is tetrabasic, forming salts  $M_2FeCy_4$ ,  $M_3FeCy_4$ ,  $M^+M_2FeCy_4$ , &c.

*Ferrocyanides (Ferroprussiates)*. *Salts of ferrocyanhydric acid*  $H_2FeCy_4$ . These salts are not to be regarded as double cyanides; v. remarks *supra*. Many ferrocyanides are coloured; the production of one of these salts by adding  $K_2FeCy_4$  to a metallic salt solution is often used as a test for different metals. The soluble alkali ferrocyanides are not poisonous. Those ferrocyanides which are completely dehydrated by heat without decomposition are decomposed at higher temperatures into  $N$  and  $Fe$  carbide, and either a cyanide of the other metal, e.g.  $K_2FeCy_4$ , or  $N$  and metallic carbide, e.g.

$PbFeCy_4$ , or  $Cy$  and metal, e.g.  $Ag_2FeCy_4$ . Those ferrocyanides which cannot be completely dehydrated without decomposition are resolved at a high temperature into  $HCN$ ,  $CO_2$ ,  $NH_3$ , and either a mixture or compound of each of the metals with  $C$ . When aqueous solutions of the alkali ferrocyanides are electrolysed alkali separates at the negative pole, and  $HCN$  and Prussian blue at the positive pole; if the positive pole is  $Cu$ ,  $CuCy_4$  is formed. Heated with conc.  $H_2SO_4$ , ferrocyanides give  $SO_2$ ,  $CO$ ,  $CO_2$ , and  $N$ , and form sulphates of  $NH_4$ ,  $Fe$ , and the other metal of the original salt. Some ferrocyanides are decomposed by  $H_2S$  giving metallic sulphides and ferrocyanhydric acid, e.g.  $Pb_2FeCy_4$ . Ferrocyanides of heavy metals are generally decomposed by aqueous alkali, giving alkali ferrocyanides and a pp. of the hydrated oxide of the heavy metal.

ALUMINIUM FERROCYNANIDES

$Al_3(FeCy_4)_3 \cdot 2H_2O$  (Wyrubow, *A. Ch.* [5] 8, 444; Tissier, *C. R.* 45, 232). By mixing conc. solutions of alum and  $K_2FeCy_4$ ; many reactions have been tried to give an  $Al$  salt, but there is doubt as to the isolation of a definite salt.

AMMONIUM FERROCYNANIDE

$(NH_4)_2FeCy_4 \cdot 6H_2O$ . Produced by action of  $NH_4Aq$  on Prussian blue (Schecle), or by adding  $(NH_4)_2CO_3$  to  $Pb_2FeCy_4$  (Berzelius). Best prepared by neutralising  $H_2FeCy_4Aq$  by  $NH_4Aq$ , and adding alcohol (Bette, *A.* 23, 120; v. also Bunsen, *P.* 36, 404). White crystals, isomorphous with  $K_2FeCy_4$ ; sol. in water, insol. in alcohol.

Double salts  $(NH_4)_2FeCy_4 \cdot 2NH_4Cl \cdot 3H_2O$ , and  $(NH_4)_2FeCy_4 \cdot 2NH_4Br \cdot 3H_2O$ ; obtained by mixing solutions of the constituent salts and cooling (Bunsen, *P.* 36, 404; Himly a. Bunsen, *P.* 38, 208; crystalline forms are given).

Double ferrocyanides of ammonium  $(NH_4)_2Cu_2FeCy_4$  (Schulz, *J. pr.* 68, 257).  $(NH_4)_2Li_2FeCy_4 \cdot 3H_2O$  (Wyrubow, *A. Ch.* [4] 21, 271).  $(NH_4)_2K_2FeCy_4 \cdot 3H_2O$ ; obtained by acting on  $K_2FeCy_4Aq$  in presence of  $NH_4$  by lactose or glucose until the solution is yellow, and then adding alcohol (Reindel, *J. pr.* 65, 450).  $(NH_4)_2K_2FeCy_4 \cdot 3H_2O$ ; by decomposing  $BaK_2FeCy_4$  (v. Barium ferrocyanide) by  $(NH_4)_2SO_4Aq$ , or by treating  $FeK_2FeCy_4$  with  $NH_4Aq$  (Reindel, *J. pr.* 76, 342; 100, 6; Playfair, *J. pr.* 63, 287).

ANTIMONY FERROCYNANIDE

$Sb_2(FeCy_4)_2 \cdot 25H_2O$  (Atterberg, *Bl.* [2] 24, 355). Yellow pp. by adding  $SbCl_3$  to  $K_2FeCy_4Aq$ .

BARIUM FERROCYNANIDE

$Ba_2FeCy_4 \cdot 6H_2O$  (Berzelius, *Lehrb.* 4, 400 [4th ed.]; Wyrubow, *A. Ch.* [4] 16, 280). Formed by passing air over a heated mixture of  $C$  and  $BaCO_3$ , and then acting with  $FeSO_4$ ; by boiling Prussian blue with  $BaO$ , filtering, and crystallising by cooling; or by boiling  $K_2FeCy_4Aq$  with an equivalent quantity of  $BaCl_2$ , filtering, and cooling. Yellow monoclinic prisms; sol. in 1,000 parts water at  $15^\circ$ , and in 100 parts at  $75^\circ$ .

DOUBLE FERROCYNANIDES OF BARIUM

$BaK_2FeCy_4 \cdot 3H_2O$  (Bunsen, *P.* 36, 404; Reindel, *J. pr.* 76, 342; Mosander, *P.* 25, 390; Duflos, *S.* 65, 233). Crystallises with  $6H_2O$  according to Wyrubow (*A. Ch.* [4] 21, 271). By mixing conc. solutions of  $BaCl_2$  and  $K_2FeCy_4$ , the latter in excess. Reacts with soluble sulphates giving  $BaSO_4$ , and double ferrocyanides of the form  $M^+K_2FeCy_4$  (Reindel, *l.c.*).

*Beryllium ferrocyanide*

$\text{Be}_2\text{FeCy}_6 \cdot 4\text{BeO} \cdot \text{H}_2\text{O}$  (Atterberg, *Bl.* [2] 19, 497; cf. Toozynsky, *Z.* 1871, 276). By the action of  $\text{BeSO}_4\text{Aq}$  on  $\text{Pb}_2\text{FeCy}_6$  in presence of  $\text{NH}_3$ .

*Bismuth ferrocyanides.*  $\text{Bi}_2(\text{FeCy}_6)_3$ ; almost colourless salt obtained by adding solution of  $\text{Bi}_3\text{NO}_3$  in smallest excess of air-free  $\text{HNO}_3\text{Aq}$  to air-free  $\text{K}_2\text{FeCy}_6\text{Aq}$  in cooled flask, washing with air-free water in atmosphere of  $\text{CO}_2$  and drying over  $\text{H}_2\text{SO}_4$  in *vacuo* (Pattison Muir, *C. J.* [2] 16, 661; 17, 40). Salt soon decomposes when moist, giving off  $\text{HCN}$  and forming Prussian blue. Decomposed by  $\text{Cl}$  or  $\text{Br}$  in presence of alkali. Changed by  $\text{Cl}$  or dilute  $\text{HNO}_3\text{Aq}$  in the cold to ferri-cyanide  $\text{Bi}_3(\text{FeCy}_6)_2$ . Wyrubow (*A. Ch.* [5] 8, 444) says that  $\text{Bi}_2\text{FeCy}_6 \cdot 5\text{H}_2\text{O}$  is produced by action of  $\text{Bi}_3\text{NO}_3$  with  $\text{H}_2\text{FeCy}_6$ ; but the data are meagre.

Double ferrocyanide of bismuth. According to Wyrubow (*loc.*) addition of  $\text{K}_2\text{FeCy}_6$  to  $\text{Bi}(\text{NO}_3)_3$  in  $\text{HNO}_3\text{Aq}$  ppt.  $\text{BiK}_2\text{FeCy}_6 \cdot 4\text{H}_2\text{O}$ ; the existence of this salt wants confirmation.

*Cadmium ferrocyanides.* None isolated.

Double ferrocyanides of cadmium  $\text{CdK}_2\text{FeCy}_6 \cdot \text{H}_2\text{O}$  (Hermann, *A.* 115, 235); or  $\text{Cd}_2\text{K}_2(\text{FeCy}_6)_2 \cdot 11\text{H}_2\text{O}$  (?) (Wyrubow, *A. Ch.* [5] 8, 444). By adding  $\text{K}_2\text{FeCy}_6\text{Aq}$  to solution of a  $\text{Cd}$  salt.

*Calcium ferrocyanide*  $\text{Ca}_2(\text{FeCy}_6)_2 \cdot 12\text{H}_2\text{O}$ . Triclinic crystals; sol. in 2 parts of water at  $90^\circ$ ; by decomposing Prussian blue by  $\text{CaO}$  *Aq.* filtering, exposing to the air, filtering from  $\text{CaCO}_3$ , and evaporating (Wyrubow, *A. Ch.* [4] 16, 280; Berzelius, *S.* 30, 12).

Double ferrocyanides of calcium  $\text{CaK}_2\text{FeCy}_6 \cdot 3\text{H}_2\text{O}$  (Mosander, *P.* 25, 390; Marchand, *J. Chim. Méd.* 20, 558); by ppg. a  $\text{Ca}$  salt by excess of  $\text{K}_2\text{FeCy}_6\text{Aq}$ .  $\text{CaNa}_2(\text{FeCy}_6)_2$  (Wyrubow, *A. Ch.* [4] 21, 271).  $\text{CaSrFeCy}_6 \cdot 10\text{H}_2\text{O}$  (*W.*, *loc.*).

*Cerium ferrocyanide*  $\text{Ce}_2(\text{FeCy}_6)_2 \cdot 30\text{H}_2\text{O}$  (Wyrubow, *A. Ch.* [5] 8, 444). Double ferrocyanides of  $\text{Ce}$  and  $\text{K}$  are also said to exist; but none of the salts has been thoroughly examined (*v. Jolin*, *Bl.* [2] 21, 535).

*Chromium ferrocyanides.* Addition of  $\text{K}_2\text{FeCy}_6\text{Aq}$  to  $\text{CrCl}_2\text{Aq}$  gives a yellow pp. probably  $\text{Cr}_2\text{FeCy}_6$  (Stridsberg, *J.* 1861, 304; cf. Kaiser, *A. Suppl.* 3, 163).

*Cobalt ferrocyanides.*  $\text{K}_2\text{FeCy}_6\text{Aq}$  added to a  $\text{Co}$  salt solution produces a blue pp. which soon changes in air to reddish; this pp. is a ferrocyanide of  $\text{Co}$ , but the exact composition has not been accurately determined. Wyrubow (*A. Ch.* [5] 8, 444) gives the formulae  $\text{Co}_2\text{FeCy}_6 \cdot 7\text{H}_2\text{O}$ ,  $\text{Co}_2(\text{FeCy}_6)_2 \cdot 22\text{H}_2\text{O}$ ,  $\text{CoK}_2\text{FeCy}_6$ , and  $\text{Co}_2\text{K}_2(\text{FeCy}_6)_2$ , to the pp. obtained under different conditions. Compounds of  $\text{Co}$  ferrocyanides with  $\text{NH}_3$  are described by Curda (*Z.* 1869, 369), and by Gintl (*Z.* 1868, 525); the formulae  $\text{Co}_2\text{FeCy}_6 \cdot 12\text{NH}_3 \cdot 9\text{H}_2\text{O}$ , and  $\text{Co}_2\text{FeCy}_6 \cdot 8\text{NH}_3 \cdot 10\text{H}_2\text{O}$  are given; a salt having the composition  $\text{Co}_2\text{FeCy}_6(\text{NO}_3)_2 \cdot 10\text{NH}_3 \cdot 7\text{H}_2\text{O}$  is described by Gibbs (*A.* 104, 150, 296; cf. Braun, *A.* 132, 33).

*Copper ferrocyanides.* The brown-red pp. obtained by adding  $\text{K}_2\text{FeCy}_6$  to a  $\text{Cu}$  salt solution is more or less pure  $\text{Cu}_2\text{FeCy}_6$ ; it is better prepared by using  $\text{H}_2\text{FeCy}_6\text{Aq}$ , as the pp. obtained by  $\text{K}_2\text{FeCy}_6$  is mixed with  $\text{Cu-K}$  ferro-

cyanides (*q.* Williamson, *A.* 57, 225). The pp. dried over  $\text{H}_2\text{SO}_4$  is said to contain  $7\text{H}_2\text{O}$  (Rammelsberg, *P.* 74, 65), or  $9\text{H}_2\text{O}$  (Mouthiers, *A.* 64, 297), or  $10\text{H}_2\text{O}$  (Wyrubow, *A. Ch.* [5] 8, 444). If an excess of  $\text{K}_2\text{FeCy}_6$  is used as pptant., double  $\text{Cu-K}$  ferrocyanides are obtained; the formulae  $\text{CuK}_2\text{FeCy}_6 \cdot \text{H}_2\text{O}$ , and  $\text{Cu}_2\text{K}_2(\text{FeCy}_6)_2 \cdot 12\text{H}_2\text{O}$ , are given (Rammelsberg, *P.* 74, 65; Schulz, *J. pr.* 68, 257; Wyrubow, *A. Ch.* [5] 8, 444; Reindel, *J. pr.* 103, 166). The salt  $\text{CuNa}_2\text{FeCy}_6$  is described by Schulz (*loc.*).

Double compounds of cupric ferrocyanide. By ppg. an ammoniacal solution of  $\text{CuO}$  by  $\text{K}_2\text{FeCy}_6$ , the salt  $\text{Cu}_2\text{FeCy}_6 \cdot 4\text{NH}_3 \cdot \text{H}_2\text{O}$  is formed (Bunsen, *P.* 34, 134; Mouthiers, *A.* 61, 297). By digesting  $\text{Cu}_2\text{FeCy}_6$  with  $\text{NH}_4\text{Aq}$  crystalline  $\text{Cu}_2\text{FeCy}_6 \cdot 8\text{NH}_3 \cdot \text{H}_2\text{O}$  is formed (Mouthiers, *loc.*; Guyard, *Bl.* [2] 31, 438).

Cuprous ferrocyanide. This salt is said to be formed by adding  $\text{K}_2\text{FeCy}_6\text{Aq}$  to  $\text{Cu}_2\text{Cl}_2$  in  $\text{HClAq}$ ; it probably has the composition  $\text{Cu}_2\text{FeCy}_6$  (Proust). The following double cuprous-potassium (and sodium) ferrocyanides have been obtained:— $\text{Cu}_2\text{K}_2\text{FeCy}_6 \cdot 1\frac{1}{2}\text{H}_2\text{O}$ ;  $\text{Cu}_2\text{Na}_2\text{FeCy}_6$  (Schulz, *J. pr.* 68, 257);  $\text{CuK}_2\text{FeCy}_6 \cdot x\text{H}_2\text{O}$  (Bolley, *A.* 106, 228; Wonfor, *C. J.* 15, 357).

*Didymium and Erbium ferrocyanides.* The double ferrocyanides

$\text{DiK}_2\text{FeCy}_6 \cdot 4\text{H}_2\text{O}$ , and  $\text{ErK}_2\text{FeCy}_6 \cdot 4\text{H}_2\text{O}$  are said to be produced by adding  $\text{K}_2\text{FeCy}_6\text{Aq}$  to salts of  $\text{Di}$  and  $\text{Er}$  respectively (Clève, *Bl.* [2] 21, 196; Clève & Hoeglund, *Bl.* [2] 18, 197).

*Iron ferrocyanides.* Ferrous ferrocyanide,  $\text{Fe}_2\text{FeCy}_6$ ; and ferric ferrocyanide,  $\text{Fe}_3(\text{FeCy}_6)_2$ , are both known; also derivatives of both. In connexion with these compounds cf. *IRON FERRICYANIDES*, p. 338.

*Ferrous ferrocyanide*  $\text{Fe}_2\text{FeCy}_6$ . Obtained by ppg. ferrous salts by  $\text{H}_2\text{FeCy}_6$ ; if  $\text{K}_2\text{FeCy}_6$  is used the pp. always contains  $\text{K}$ . Also formed when Prussian blue reacts with  $\text{H}_2\text{S}$ . It is obtained pure by boiling  $\text{H}_2\text{FeCy}_6\text{Aq}$  in absence of air (Aschoff, *Ar. Ph.* [2] 106, 257).  $3\text{H}_2\text{FeCy}_6 = \text{Fe}_2\text{FeCy}_6 + 12\text{HCN}$ .] White amorphous pp. soon oxidised in air with production of blue-coloured compounds; reaction may perhaps be  $3(\text{Fe}_2\text{FeCy}_6) + 3\text{O} + 3\text{H}_2\text{O} = \text{Fe}_3(\text{OH})_2 + \text{Fe}_3(\text{FeCy}_6)_2$  (Brlenmeyer, *Lehrbuch der organ. Chemie* [1867], 148 et seq.).

Double ferrocyanide derived from ferrous ferrocyanide.

*Potassium ferrous ferrocyanide*  $\text{K}_2\text{Fe}_2\text{FeCy}_6$ . (*Everitt's salt*.) Obtained by decomposing  $\text{K}_2\text{FeCy}_6$  with hot dilute  $\text{H}_2\text{SO}_4\text{Aq}$ , in making  $\text{HCN}$  [ $2\text{K}_2\text{FeCy}_6\text{Aq} + 3\text{H}_2\text{SO}_4\text{Aq} = 6\text{HCN} + 3\text{K}_2\text{SO}_4\text{Aq} + \text{K}_2\text{Fe}_2\text{FeCy}_6$ ] (Williamson, *A.* 57, 225; Everitt, *P. M.* [3] 6, 97). White microscopic quadrate crystals, becoming blue in air; oxidisers produce potassium-ferric ferrocyanide,  $\text{FeK}_2\text{FeCy}_6$ . Also produced by boiling  $\text{H}_2\text{FeCy}_6\text{Aq}$  with  $\text{K}_2\text{SO}_4$  (Aschoff, *Ar. Ph.* [2] 106, 257); probably always present in the white-blue pp. obtained by adding  $\text{K}_2\text{FeCy}_6\text{Aq}$  to ferrous salts (Aschoff, *loc.*).

*Ferric ferrocyanide*  $\text{Fe}_3(\text{FeCy}_6)_2$ . (*Prussian blue*.) This body was accidentally discovered in 1704 by Diesbach, a colour-maker in Berlin. It was afterwards found that the blue compound could be prepared by calcining blood with potash and then adding sulphate of iron.

In 1724 Woodward of London prepared the colouring matter by deflagrating cream of tartar with nitre, calcining the residue with ox-blood, dissolving in water, and ppg. by alum and sulphate of iron; he thus obtained a greenish pp. which turned blue when treated with hydrochloric acid. More or less pure ferric ferrocyanide is obtained commercially by mixing  $K_4FeC_6Aq$  with partially oxidised ferrous sulphate, and oxidising the light-blue pp. thus formed by exposure to air or by the action of  $Cl$ ,  $HNO_3Aq$ , *aqua regia*, or alkaline hypochlorites; the blue body thus formed, known commercially as *Prussian blue*, is a mixture of ferric ferrocyanide,  $Fe_3(FeC_6)_n$ , with ferrous ferro-cyanide  $*Fe_2FeC_6$ , ferrous ferricyanide  $Fe_3(FeC_6)_2$  (known commercially as *Turnbull's blue*), and probably one or more of the K-Fe ferro- or ferricyanides (*v. post*). The simultaneous production of iron ferrocyanide (Prussian blue) and iron ferricyanide (Turnbull's blue) is probably explained by the fact that both ferrous and ferric salts are present, and that ferric salts oxidise ferro- to ferricyanides, while ferrous salts reduce ferric to ferro-cyanides (*v. Skraup, W. A. B., 74 (2nd part) Juriheft, 1876*). The blue pp. obtained by adding  $K_4FeC_6Aq$  to excess of a ferric salt solution is nearly pure ferric ferrocyanide,  $Fe_3(FeC_6)_2$ ; as thus prepared the substance is known commercially as *Pais blue*. The name *Prussian blue* is often extended to all the blue pps. obtained by adding iron salts to K ferro- or ferricyanide. For an account of the manufacture of Prussian blues *v. DICTIONARY OF TECHNICAL CHEMISTRY*.

**Formation.**—1. By the reaction of ferric salts with  $K_4FeC_6Aq$  (*v. supra*); if the ferric salt is kept in excess, approximately pure  $Fe_3(FeC_6)_2$  is obtained; if the  $K_4FeC_6$  is in excess the pp. always contains K-Fe ferrocyanide,  $K_2FeFeC_6$ .—2. By adding a ferrous and a ferric salt to  $K_4FeC_6Aq$ , or to  $H_2C_6Aq$  with excess of KOH added, and then adding acid to dissolve the  $Fe(OH)_2$  and  $Fe(OH)_3$  ppd. by the KOH or the  $K_4FeC_6$ . [ $18KC_6Aq + 3FeSO_4Aq = 3K_2FeC_6Aq + 3K_2SO_4Aq$ ;  $3K_2FeC_6Aq + 4FeCl_3Aq = 12KClAq + Fe_3(FeC_6)_2$ .]—3. The action of air, or other oxidiser, on  $H_2FeC_6$ , or on ferrous ferrocyanide,  $Fe_2FeC_6$ , forms  $Fe_3(FeC_6)_2$ .

**Preparation.**— $K_4FeC_6Aq$  is added to  $FeCl_3Aq$  keeping the latter in excess; the pp. is digested with  $FeCl_3Aq$  to remove any  $K_2FeFeC_6$ , thoroughly washed and dried. Or  $H_2FeC_6$  is used in place of  $K_4FeC_6$ ; in this case the pp. is pure  $Fe_3(FeC_6)_2$ .

**Properties.**—Dark-blue amorphous solid with lustre resembling that of copper. Obtained in lustrous crystals by spontaneous evaporation of solution in conc.  $HClAq$  (Gintl, *D. P. J.* 235, 243). Does not become perfectly dehydrated until heated to c.  $250^\circ$ ; complete dehydration is accompanied by partial decomposition, with evolution of  $NH_3$  and  $(NH_4)_2CO_3$  (*v. Reimann a. Carius, A.* 113, 39; *Skraup, A.* 186, 371; *Rammelsberg, A.* 64, 298). Strongly heated it glows and is burnt to  $Fe_2O_3$ . Insoluble in water, alcohol, ether, oils, and dilute acids; sol. in conc.  $HClAq$ , addition of water ppts. the original compound; sol. in  $H_2C_2O_4Aq$ , also in  $(NH_4)_2$  tar-

trate solution; is entirely ppd. from solution in  $H_2C_2O_4Aq$  by exposure to sunlight (Schoras, *B.* 3, 12).

**Reactions.**—1. *Heat* alone decomposes  $Fe_3(FeC_6)_2$ , evolving  $CO$ ,  $CO_2$ ,  $NH_3$ ,  $HCN$ , and  $(NH_4)_2CO_3$ .—2. *Heated in air* it is burnt to  $Fe_2O_3$ ,  $NH_3$ ,  $Cy$ , and  $CO_2$ .—3. Decomposed by *alkalis* (including  $MgO$ ) to  $Fe_2O_3$  and  $K_4FeC_6Aq$ ; similar change is effected by  $K_2CO_3Aq$ , and by excess of  $NH_3Aq$ .—4. Boiled with *mercuric oxide and water*,  $Fe_2O_3$  and  $HgC_2$  are formed.—5. With *lead oxide*,  $Fe_2O_3$ ,  $Pb_2FeC_6$ , and  $K_4FeC_6$  are produced.—6. Reduced by *sulphurated hydrogen*, also by *iron or zinc*, to white ferrous ferrocyanide  $Fe_2FeC_6$ . For account of *Soluble Prussian blue v. Potassium-ferrous ferricyanide* under *Ferrous ferricyanide*.

Double ferrocyanide derived from ferric ferrocyanide.

**Ammonio-ferric ferrocyanide**  
 $Fe_3(FeC_6)_2 \cdot 6NH_3 \cdot 9H_2O$  (Mouthiers, *J. Ph.* 9, 262). When excess of  $NH_3Aq$  is added to  $FeCl_3Aq$  and the liquid is filtered into  $K_4FeC_6Aq$ , a white pp. forms which soon becomes blue in the air; this blue solid when heated with  $NH_3$  tartrate solution at  $60^\circ$ – $80^\circ$  for some hours to dissolve  $Fe_2O_3$ , leaves blue ammonio-ferric ferrocyanide, which is washed with water, and dried below  $100^\circ$ . The compound evolves  $HCN$  at  $100^\circ$ ; no  $NH_3$  is evolved below  $160^\circ$ . The same compound is the first product of the action of  $NH_3Aq$  on  $Fe_3(FeC_6)_2$  (Mouthiers, *l.c.*). Because of the stability of this compound it may perhaps be regarded as *ferric-ferric-ammonium ferrocyanide*  $(Fe_2N_3H_3Fe_3)(FeC_6)_2$ .

**Lanthanum ferrocyanide.**—None has been isolated, but the double salt  $LaK_2FeC_6 \cdot 4H_2O$  is described by Clève (*Bull.* [2] 21, 196; *v. also* Wyrubow, *A. Ch.* [5] 8, 444).

**Lead ferrocyanide**  $Pb_2FeC_6 \cdot 3H_2O$ . White pp. formed by adding  $K_4FeC_6Aq$  to  $Pb(NO_3)_2Aq$  and washing repeatedly with water (Berzelius; Wyrubow, *A. Ch.* [5] 8, 444). Loses all  $H_2O$  at moderate temperature. Dehydrated salt heated in air evolves  $N$  and leaves mixture of carbides of  $Fe$  and  $Pb$ .

**Lithium ferrocyanide**  $Li_2FeC_6 \cdot 9H_2O$ ; very soluble salt; deliquescent crystals (Wyrubow, *A. Ch.* [4] 16, 280). The double salt  $Li_2K_2FeC_6 \cdot 3H_2O$  is described by Wyrubow (*A. Ch.* [4] 21, 271).

**Magnesium ferrocyanide**  
 $Mg_2FeC_6 \cdot 12H_2O$ . By dissolving  $MgCO_3$  in  $H_2FeC_6Aq$  and evaporating; pale yellow crystals; sol. 3 pts. cold water; unchanged in air (Bette, *A.* 22, 148; 23, 115). The double salt  $MgK_2FeC_6$  is described by Berzelius (*Lehrb.* 4, 400 [4th ed.]).

**Manganese ferrocyanide**  
 $Mn_2FeC_6 \cdot 7H_2O$ ; white pp. by adding  $K_4FeC_6Aq$  to solution of a manganous salt (Wyrubow, *A. Ch.* [5] 8, 444; Mosander, *P.* 26, 890).

**Manganese-potassium ferrocyanide**  
 $MnK_2FeC_6$  (Berzelius; Wyrubow, *l.c.*).

**Mercury ferrocyanides.** Mercurous and mercuric salts give pps. with  $K_4FeC_6$ , but the composition of the pps. was not accurately determined. Bunsen (*P.* 34, 134) obtained a *compound of ammonia with mercuric ferrocyanide*  $Hg_2FeC_6 \cdot 2NH_3 \cdot H_2O$  by mixing cooled solutions of  $Hg(NO_3)_2Aq$ ,  $NH_3Aq$ , and  $NH_4NO_3Aq$ .

**Molybdenum ferrocyanides**

$\text{Mo}_2\text{FeCy}_6 \cdot 8\text{H}_2\text{O}$ ;  $\text{Mo}_2\text{FeCy}_6 \cdot 14\text{H}_2\text{O}$ ;  
 $\text{Mo}_2\text{FeCy}_6 \cdot 20\text{H}_2\text{O}$ ; and the double salt  
 $\text{Mo}_2\text{K}_2\text{FeCy}_6 \cdot 20\text{H}_2\text{O}$  (?) (Wyrubow, *A. Ch.* [5] 8,  
 444; cf. Atterberg, *Bt.* [2] 24, 355). These salts  
 are said to be formed by reactions between  
 $\text{K}_2\text{FeCy}_6\text{Aq}$  and salts of Mo, or in some cases  
 $\text{NH}_4$  molybdate; their composition is doubtful.

**Nickel ferrocyanides.** According to  
 Wyrubow (*A. Ch.* [5] 8, 444)  $\text{K}_2\text{FeCy}_6$ , added to  
 a salt of Ni, ppts.  $\text{NiK}_2\text{FeCy}_6 \cdot 3\text{H}_2\text{O}$ : if excess of  
 ferrocyanide is used the salt is said to have the  
 composition  $\text{Ni}_2\text{K}_2\text{FeCy}_6 \cdot 6\frac{1}{2}\text{H}_2\text{O}$ . By using  
 $\text{H}_2\text{FeCy}_6\text{Aq}$  in place of the K salt, salts are  
 obtained which Wyrubow formulates as  
 $\text{Ni}_2(\text{FeCy}_6)_2$  and  $\text{Ni}_2\text{FeCy}_6 \cdot 11$  (or 14)  $\text{H}_2\text{O}$ . By  
 adding  $\text{K}_2\text{FeCy}_6\text{Aq}$  to a Ni salt solution contain-  
 ing  $\text{NH}_4$  various salts are formed, and from  
 these again others are obtained by treatment  
 with  $\text{NH}_4\text{Aq}$ ; the following are described:—  
 $\text{Ni}_2\text{FeCy}_6 \cdot 10\text{NH}_4 \cdot 4\text{H}_2\text{O}$ ;  $\text{Ni}_2\text{FeCy}_6 \cdot 4\text{NH}_3 \cdot \text{H}_2\text{O}$   
 (Reynoso, *A. Ch.* [3] 30, 252);  
 $\text{Ni}_2\text{FeCy}_6 \cdot 2\text{NH}_3 \cdot 4(\&9)\text{H}_2\text{O}$ ;  $\text{Ni}_2\text{FeCy}_6 \cdot 8\text{NH}_3 \cdot 4\text{H}_2\text{O}$ ;  
 $\text{Ni}_2\text{FeCy}_6 \cdot 12\text{NH}_3 \cdot 9\text{H}_2\text{O}$  (Gintl, *Z.* 1868, 525).

**Niobium ferrocyanides.**—None certainly  
 isolated. Several double salts are described  
 (Wyrubow, *A. Ch.* [5] 8, 444; Atterberg, *Bt.* [2]  
 24, 356); they are said to be formed by adding  
 $\text{K}_2\text{FeCy}_6\text{Aq}$  to niobic acid in presence of  $\text{KHC}_2\text{O}_4$ :  
 $\text{Nb}_2(\text{K}_2\text{FeCy}_6)_2 \cdot 67\text{H}_2\text{O}$  (?);  $\text{Nb}_2\text{K}_2\text{FeCy}_6 \cdot 39\text{H}_2\text{O}$  (?);  
 $(\text{NbO})_2\text{K}_2(\text{FeCy}_6)_2 \cdot 10\text{H}_2\text{O}$  (?).

**Potassium ferrocyanide**  $\text{K}_2\text{FeCy}_6$ .  
 (Yellow prussiate of potash. Ferropotassium  
 of potash.) Discovered about 1750 by Macquer;  
 obtained by him by boiling Prussian blue with  
 potash. Berthollet showed that the iron in it  
 was an essential part of the salt. H.F.  
 $[\text{K}_2\text{FeCy}_6] = 367,200$ ;  $[\text{K}_2\text{FeCy}_6\text{Aq}] = 5,400$   
 (Berthollet, *C. R.* 91, 82).

**Formation.**—1. By fusing nitrogenous animal  
 matter (horn, feathers, dried blood, leather-  
 clippings, &c.) with  $\text{K}_2\text{CO}_3$  and scrap iron,  
 lixiviating with water, filtering, and crystallising;  
 $\text{KC}_2\text{O}_4$  is formed, and on addition of water this  
 reacts with the iron to produce  $\text{K}_2\text{FeCy}_6$  (Liebig,  
*A.* 38, 20; Nöllner, *A.* 108, 8; Hoffmann,  
*D. P. J.* 151, 63).  $2\text{Fe} + 12\text{KCNAq} + 4\text{H}_2\text{O}$   
 $= 2\text{K}_2\text{FeCy}_6\text{Aq} + 4\text{KOH} + 2\text{H}_2$ ; or in presence  
 of air  $2\text{Fe} + 12\text{KCNAq} + 2\text{H}_2\text{O} + \text{O}_2$   
 $= 2\text{K}_2\text{FeCy}_6\text{Aq} + 4\text{KOH} + 2\text{H}_2$ .—2. By heating  
 $\text{NH}_4\text{SCN}$  with scrap iron to dull redness, and  
 dissolving out with water (Géls, *W. J.* 1862, 283;  
 1863, 321; Fleck, *W. J.* 1863, 323; Alander,  
*D. P. J.* 226, 318; Tscherniak, *A. Gumburg, J.*  
 1878, 1123).—3. By the action of  $\text{KCNAq}$  on  
 $\text{Fe}(\text{OH})_3$ ,  $\text{FeCO}_3$ , or  $\text{FeS}$ , &c. (Fresenius, *A.*  
 Haidlen, *A.* 43, 132; Liebig, *A.* 38, 20).—4. By  
 reaction between  $\text{KOH} + \text{Aq}$  and various ferro-  
 cyanides.

**Preparation.**—Pure Prussian blue  $\text{Fe}_4(\text{FeCy}_6)_3$   
 is added to boiling  $\text{KOH} + \text{Aq}$  so long as the blue  
 colour changes to brown, the solution is filtered,  
 evaporated, and the salt is recrystallised from  
 water. Impure  $\text{K}_2\text{FeCy}_6$  (prepared from com-  
 mercial Prussian blue) generally contains  $\text{K}_2\text{CO}_3$ ,  
 $\text{K}_2\text{SO}_4$ , &c., and sometimes Prussian green; it  
 may be purified, according to Berzelius, by heat-  
 ing until it effloresces, and then to its melting-  
 point, dissolving in water, filtering from C and  
 Fe carbide, adding acetic acid to convert  $\text{K}_2\text{CO}_3$

and  $\text{KC}_2\text{O}_4$  into acetate, adding Ba acetate little by  
 little to pp. sulphates, filtering, evaporating, ppg.  
 $\text{K}_2\text{FeCy}_6$  by alcohol, and recrystallising twice  
 from water.

**Properties.**—Reddish-yellow quadratic pyra-  
 mids (Bunsen, *P.* 36, 404); crystallises with  
 $3\text{H}_2\text{O}$ . S.G. 1.86 (*W. J.* 1875, 503). Not  
 poisonous. Loses all  $\text{H}_2\text{O}$  at  $60^\circ$ – $80^\circ$ ; un-  
 changed at ordinary temperatures. Sol. c. 4 pts.  
 cold  $\text{H}_2\text{O}$  and in c. 2 pts. at  $100^\circ$ ; insol. alcohol;  
 1,000 c.c.  $\text{K}_2\text{FeCy}_6\text{Aq}$  saturated at  $15^\circ$  has S.G.  
 1.144, and contains 258.77 g. salt and 885.34 g.  
 water (Michel, *A. Kraft, A. Ch.* [3] 41, 471).  
 Solution decomposed in sunlight with ppn. of  
 Prussian blue and evolution of  $\text{HCN}$ .

**Reactions.**—1. Heated in closed vessel melts at  
 little above red heat, evolves N, and leaves mix-  
 ture of  $\text{KC}_2\text{O}_4$  and Fe carbide; if salt is not de-  
 hydrated it gives off  $\text{CO}$ ,  $\text{NH}_3$ ,  $\text{HCN}$ , and N.—  
 2. Heated to redness in air gives  $\text{KC}_2\text{O}_4$ ; same  
 product formed by heating with reducible metal-  
 lic oxides.—3. Changed slowly by ozone into  
 $\text{K}_2\text{FeCy}_6$ ; not, however, acted on by oxygen.—  
 4.  $\text{K}_2\text{FeCy}_6\text{Aq}$  electrolysed forms  $\text{K}_2\text{FeCy}_6$  at po-  
 sitive, and  $\text{KOH} + \text{Aq}$  and H at negative, pole (Schlag-  
 denhaufen, *J.* 1863, 305).—5.  $\text{K}_2\text{FeCy}_6\text{Aq}$  is changed  
 to  $\text{K}_2\text{FeCy}_6\text{Aq}$  by oxidisers, e.g.  $\text{KMnO}_4\text{Aq}$ ,  $\text{PbO}_2$ ,  
 $\text{MnO}$  (Brodie, *P.* 120, 302; Weltzien, *A.* 138,  
 129; Reindel, *J. pr.* 76, 342; Böttger, *J. pr.* 76,  
 238; Braun, *J. pr.* 90, 356).—6. Chlorine forms  
 $\text{KCl}$  and  $\text{K}_2\text{FeCy}_6$ ; bromine reacts similarly to  
 $\text{Cl}$ .—7. Iodine dissolves in warm  $\text{K}_2\text{FeCy}_6$ ,  
 to form an olive-green liquid, from which crystals  
 of a double compound of KI and  $\text{K}_2\text{FeCy}_6$   
 $(\text{KI.K}_2\text{FeCy}_6)$  separate on cooling (Mohr, *A.* 105,  
 57; Blomstrand, *J. pr.* [2] 3, 207; Preuss, *A.* 29,  
 323).—8. Fairly conc. nitric acid forms nitro-  
 prussic acid (*q.v.* p. 341); very conc. nitric acid  
 decomposes the salt entirely, forming N, Cy,  
 $\text{NO}$ ,  $\text{CO}$ ,  $\text{KNO}_3$ , and  $\text{Fe}_2\text{O}_3$ .—9. Dilute sulphuric  
 acid forms  $\text{H}_2\text{FeCy}_6\text{Aq}$  if cold, if the  $\text{H}_2\text{SO}_4\text{Aq}$  is  
 warm  $\text{HCy}$  is evolved ( $2\text{K}_2\text{FeCy}_6\text{Aq} + 3\text{H}_2\text{SO}_4\text{Aq}$   
 $= 6\text{HCyAq} + \text{Fe}_2(\text{FeCy}_6)_2 + 3\text{K}_2\text{SO}_4\text{Aq}$ ; Witt-  
 stein, *Vierteljahr. Pharm.* 4, 515; Aschoff, *Ar.*  
*Ph.* [2] 106, 257). Heated with conc.  $\text{H}_2\text{SO}_4$   
 almost pure  $\text{CO}$  is evolved (Fownes, *P. M.*  
 [3] 24, 21)  $[\text{K}_2\text{FeCy}_6 + 6\text{H}_2\text{SO}_4 + 6\text{H}_2\text{O}$   
 $= 2\text{K}_2\text{SO}_4 + 3(\text{NH}_4)_2\text{SO}_4 + \text{Fe}_2\text{SO}_4 + 6\text{CO}]$ .—10. De-  
 composed by boiling with mercuric oxide and  
 water,  $\text{HgCy}_6$  and  $\text{Fe}_2(\text{OH})_2$  being formed (Weith,  
*Z.* 1869, 381).—11. Boiled with sal ammoniac  
 $\text{NH}_4\text{Cy}$  is volatilised (Wyrubow, *A. Ch.* [4] 16,  
 280).—12. Ammoniacal silver nitrate forms  
 $\text{Fe}(\text{OH})_3$  and  $\text{AgCy.KCy}$ .—13.  $\text{K}_2\text{FeCy}_6$  boiled  
 with a very little ferric chloride solution forms  
 some  $\text{K}_2\text{FeCy}_6$  (Williamson, *A.* 57, 238).—  
 14.  $\text{K}_2\text{FeCy}_6\text{Aq}$  reacts with most metallic salts  
 to give ppn. of ferrocyanides (*q.v.*).

Double ferrocyanides derived from  
 potassium ferrocyanide. (Those only are  
 mentioned here which contain potassium, and  
 another metal the first letter of the name of  
 which follows P in alphabetical order; the other  
 double ferrocyanides containing K are mentioned  
 under the headings of the metal other than K).

$\text{Na}_2\text{K}_2\text{FeCy}_6 \cdot 9\text{H}_2\text{O}$  (Wyrubow, *A. Ch.* [4] 16,  
 280).

$\text{Na}_2\text{K}_2\text{FeCy}_6 \cdot 8\text{H}_2\text{O}$  (Reindel, *J. pr.* 100, 6).

$\text{NaK}_2\text{FeCy}_6 \cdot 3\text{H}_2\text{O}$  (Reindel, *J. pr.* 65, 450).

$\text{K}_2\text{SrFeCy}_6 \cdot 3\text{H}_2\text{O}$  (Wyrubow, *A. Ch.* [4] 21,  
 271).

$K_2W_2FeCy_2 \cdot 7H_2O$ ;  $K_2W_2FeCy_2 \cdot 20H_2O$  (?) (Wyrubow, *A. Ch.* [5] 8, 441).

$K_2U_2FeCy_2 \cdot 6H_2O$  (?);  $K_2UO_2 \cdot (FeCy)_2 \cdot 6H_2O$ ;  $K_2UO_2 \cdot (FeCy)_2 \cdot 12H_2O$  (W., l.c.; Atterberg, *Bl.* [2] 241, 355).

$K_2V_2(FeCy)_2$  (?) (W., l.c.);

$K_2(VO)_2(FeCy)_2 \cdot 60H_2O$  (?) (A., l.c.).

$KY.FeCy_2$  (Clève a. Hoeglund, *Bl.* [2] 18, 197). Double salts containing potassium ferrocyanide.

$K_2FeCy_2 \cdot 2KNO_3 \cdot 2NaNO_3$  (Martius, *Z.* 1866, 319; cf. Wyrubow, *A. Ch.* [1] 16, 280).

$K_2FeCy_2 \cdot 3HgCy_2 \cdot 4H_2O$  (Kane, *A.* 35, 357; Lowe, *J.* 1857, 273).

*Osmium ferrocyanide*  $Os_2FeCy_2$  (Martius, *A.* 117, 357).

*Rubidium ferrocyanide*  $Rb_2FeCy_2 \cdot 21H_2O$ . Yellow triclinic crystals. Obtained by dissolving  $Rb_2CO_3$  in  $H_2FeCy_2$  Aq, and evaporating (Picard, *J. pr.* 86, 449).

*Silver ferrocyanide*  $Ag_2FeCy_2$  (Glassford a. Napier, *P. M.* [3] 25, 71); with  $21H_2O$ , according to Wyrubow (*A. Ch.* [5] 8, 441). White pp. turning blue in the air by adding  $K_2FeCy_2$  Aq to solution of a Ag salt. Sol. in  $KCy$  Aq. Combines with  $NH_3$  to form

(Gintl, *W. A. B.* 59, 554; 60, 470). Decomposed by warm  $NH_3$  Aq to  $FeO \cdot xH_2O$  and solution of  $AgCy$  and  $NH_4Cy$  (Weith, *Z.* [2] 5, 381).

*Sodium ferrocyanide*  $Na_2FeCy_2 \cdot 12H_2O$  (Berzelius), or  $9H_2O$  when ppt. by addition of alcohol to its hot solution (Weith, *A.* 147, 329). Obtained by boiling Prussian blue with  $NaOH$  Aq, filtering, and cooling. Monoclinic, pale-yellow crystals, which effloresce in air (Reindel, *J. pr.* 102, 42).

#### *Strontium ferrocyanide*

$Sr_2FeCy_2 \cdot 15H_2O$ ; easily soluble, yellow monoclinic crystals. Obtained by dissolving  $SrCO_3$  in  $H_2FeCy_2$  Aq, evaporating, and recrystallizing the crystals which separate (Bette, *A.* 22, 148). Wyrubow (*A. Ch.* [4] 16, 280) obtained crystals with  $8H_2O$ .

*Thallium ferrocyanide*  $Tl_2FeCy_2 \cdot 2H_2O$ ; small, lustrous, yellow triclinic crystals. Formed by crystallizing a mixed solution of conc.  $K_2FeCy_2$  with conc.  $Tl_2CO_3$  Aq (Lamy a. Descloiseaux, *A. Ch.* [4] 17, 310; Wyrubow, *A. Ch.* [4] 16, 280).

*Tin ferrocyanides. Stannous ferrocyanide*  $Sn_2FeCy_2 \cdot 4H_2O$ ; white pp. by adding  $K_2FeCy_2$  to  $SnCl_2$  solution (Wyrubow, *A. Ch.* [5] 8, 444). *Stannic ferrocyanide*  $SnFeCy_2 \cdot 4H_2O$ ; brownish pp. by adding  $K_2FeCy_2$  Aq to  $SnCl_4$  solution (W., l.c.). Wyrubow describes other ferrocyanides of tin, but their composition is doubtful.

*Titanium ferrocyanides.* According to Wyrubow (*A. Ch.* [5] 8, 444) various  $Ti$  ferrocyanides are obtained by adding  $K_2FeCy_2$  Aq to solutions of  $Ti$  salts; the composition of these compounds is doubtful (cf. Atterberg, *Bl.* [2] 24, 355).

*Thorium ferrocyanide*  $Th_2FeCy_2 \cdot 4H_2O$  (Clève, *Bl.* [2] 21, 119).

*Uranium ferrocyanide*  $UFeCy_2 \cdot 10H_2O$ ;  $U_2K_2FeCy_2 \cdot 20H_2O$  (Wyrubow, *A. Ch.* [5] 8, 444).

*Vanadium ferrocyanide.* The salt  $(VO)_2FeCy_2 \cdot 11H_2O$  is said to be formed by ppg. Vol. II.

$V$  salts by  $K_2FeCy_2$  Aq (Atterberg, *Bl.* [2] 24, 355).

*Yttrium ferrocyanide.* The salt  $Y_2FeCy_2$  is said to be produced by boiling yttria with Prussian blue, filtering and evaporating slowly (Popp, *M.* 131, 179). For double  $K-Y$  salt v. *Potassium ferrocyanide*.

*Zinc ferrocyanide*  $Zn_2FeCy_2 \cdot 3H_2O$  (Schindler, *Magaz. Pharm.* 35, 71), or with  $4H_2O$  (Wyrubow, *A. Ch.* [5] 8, 444). White pp. by adding excess of  $ZnSO_4$  Aq to  $K_2FeCy_2$  Aq; or, better, by using  $H_2FeCy_2$ . If the  $ZnSO_4$  Aq contains  $NH_3$ , a double salt,  $Zn_2FeCy_2 \cdot 3NH_3 \cdot H_2O$ , is produced (Bunsen, *P.* 34, 134; Mouthiers, *A.* 64, 297).

#### FERRICYANHYDRIC ACID AND FERRICYANIDES.

*Ferricyanhydric acid*  $H_2FeCy_2$ . (*Ferricyanic acid. Hydroferricyanic acid. Ferriprussic acid. Hydrogen ferricyanide.*) Prepared by decomposing  $Pb_2(FeCy)_2$  by dilute  $H_2SO_4$  Aq (Gmelin); or, preferably, by adding to conc.  $K_2FeCy_2$  Aq two or three times its volume of very conc.  $HCl$  Aq, and collecting the acid which separates on a porous plate, and drying *in vacuo* (Schafarik, *W. A. B.* 47, 262). Forms lustrous brownish-green needles; very sol. in water and alcohol, insol. in ether; decomposed in air with evolution of  $HCN$  and production of blue-coloured residue (Posselt, *A.* 42, 163). Joannis (*C. R.* 94, 449, 541, 725) examined the thermal data for  $H_2FeCy_2$  Aq; the solution was prepared by the action of  $Br$  on  $H_2FeCy_2$  Aq:—  
 $[H_2FeCy_2 \cdot Aq, 3KOH \cdot Aq] = 43,500$ ;  $[H_2FeCy_2 \cdot Aq] = 77,400$  (gaseous  $Cy$ );  $[H_2FeCy_2 \cdot Aq, H] = 29,200$  (production of solution of  $H_2FeCy_2$  from solution of  $H_2FeCy_2$ ).

*Ferricyanides (Ferriprussiates).* Salts of *ferricyanhydric acid*. These salts are produced by the action of oxidising agents on the ferrocyanides; the action consists in the withdrawal of  $\frac{1}{2}$  of the metal of the ferrocyanide;  $M_2FeCy_2 - M = MFeCy_2$ . Alkali ferricyanides are soluble in water; most of the other ferricyanides are insoluble, and may be formed by ppn. Alkali ferricyanides give pps. with salts of many different metals.

#### *Ammonium ferrocyanide*

$(NH_4)_2FeCy_2 \cdot 3H_2O$ . Chlorine is passed into  $NH_4$  ferrocyanide solution until the liquid ceases to give a blue pp. or colour with  $FeCl_2$  Aq (free from  $FeCl_3$ ); the liquid is evaporated slowly, then cooled; the crystals of  $(NH_4)_2FeCy_2$  are separated from those of  $NH_4Cl$  formed in the reaction, and are recrystallised from water. Cannot be wholly dehydrated without partial decomposition,  $HCN$  being evolved and some Prussian blue produced (Jacquemin, *Bl.* [2] 1, 319; Bette, *A.* 23, 115).

By boiling  $K_2FeCy_2$  Aq with  $(NH_4)_2SO_4$  Aq Schaller (*Bl.* [2] 1, 275; 2, 93) obtained crystals of the double salt  $(NH_4)_2K_2FeCy_2$ . Schuler (*W. A. B.* 77, 692) obtained the double salt  $NH_4Pb_2FeCy_2 \cdot 3H_2O$ .

*Barium ferricyanide*  $Ba(FeCy)_2 \cdot 20H_2O$  (Schuler, *W. A. B.* 77, 692). By passing  $Cl$  into a solution of  $BaK_2FeCy_2$  (obtained by mixing conc.  $BaCl_2$  Aq with excess of conc.  $K_2FeCy_2$  Aq), warming to remove excess of  $Cl$ , adding alcohol, and cooling, the double salt  $BaK_2FeCy_2 \cdot 3H_2O$  was obtained (Bette, *A.* 23, 115).

*Beryllium ferricyanide* (Joczynsky, *Z.* 1871, 276). Composition undecided.

**Bismuth ferricyanide**  $\text{Bi}_2(\text{FeCy})_6$ . Brownish red pp. produced by adding  $\text{K}_2\text{FeCy}_6$  Aq to  $\text{Bi}(\text{NO}_3)_3$  dissolved in very little  $\text{HNO}_3$  Aq, washing with cold water, and drying *in vacuo* over  $\text{H}_2\text{SO}_4$ . Decomposed by boiling water with evolution of  $\text{HCN}$ . Cl. in presence of hot water, forms  $\text{Bi}_2\text{O}_3$ , Prussian blue, and  $\text{HCN}$ ; Br and  $\text{NaOH}$  Aq gives  $\text{Bi}_2\text{O}_3$  and  $\text{Fe}_2\text{O}_3$ . Reduced by Na-amalgam to  $\text{Bi}_2(\text{FeCy})_6$ .

Also obtained by reaction of dilute  $\text{HNO}_3$  Aq with  $\text{Bi}_2(\text{FeCy})_6$  (q. v.) (Pattison Muir, *C. J.* [2] 16, 654; 17, 40).

**Cadmium ferricyanide**. Yellow pp. obtained by adding  $\text{K}_2\text{FeCy}_6$  Aq to solution of a Cd salt; composition undecided. This pp. dissolves in  $\text{NH}_4$  Aq; if little  $\text{NH}_4$  Aq is used the double salt  $\text{Cd}_2(\text{FeCy})_6 \cdot 6\text{NH}_4 \cdot 3\text{H}_2\text{O}$  is formed; if much  $\text{NH}_4$  Aq is added the salt  $\text{Cd}_2(\text{FeCy})_6 \cdot 4\text{NH}_4 \cdot 2\text{H}_2\text{O}$  is produced after a time (Wyrubow, *A. Ch.* [5] 10, 413).

**Calcium ferricyanide**  $\text{Ca}_2(\text{FeCy})_{10}$  (or  $12$ )  $\text{H}_2\text{O}$  (Berzelius, *S.* 30, 12; Bette, *A.* 23, 115). Formed by the action of Cl on  $\text{Ca}_2\text{FeCy}_6$  Aq. Fine, red, deliquescent needles. The double salt  $\text{CaK}_2\text{FeCy}_6$  is described by Mosander (*P.* 25, 390).

**Cerium ferricyanide**  $\text{CeFeCy}_6 \cdot 4\text{H}_2\text{O}$  (Jolin, *Bl.* [2] 21, 535). By adding alcohol to a mixture of Ce nitrate with  $\text{K}_2\text{FeCy}_6$  Aq.

**Chromium ferricyanide**. Compound obtained by adding  $\text{K}_2\text{FeCy}_6$  to a Cr salt. Composition undecided (v. Stridsberg, *J.* 1864, 304). Christensen (*J. pr.* [2] 23, 49) describes the double compound  $\text{CrFeCy}_6 \cdot 5\text{NH}_4 \cdot 1\frac{1}{2}\text{H}_2\text{O}$ .

**Cobalt ferricyanide**  $\text{Co}_2(\text{FeCy})_6$ . Red-brown pp. obtained by adding  $\text{K}_2\text{FeCy}_6$  Aq to a Co salt (*Gm.* 7, 497). When  $\text{Co}_2(\text{FeCy})_6$  is kept in contact with  $\text{NH}_4$  Aq for a long time the double compound  $\text{Co}_2(\text{FeCy})_6 \cdot 2\text{NH}_4 \cdot 6\text{H}_2\text{O}$  is produced (Braun, *A.* 125, 153, 197).

**Copper ferricyanides**; **Cuprous ferricyanide**  $\text{Cu}_2(\text{FeCy})_6$ ; brownish red pp. formed by adding  $\text{Cu}_2\text{Cl}_2$  in  $\text{HCl}$  Aq to  $\text{K}_2\text{FeCy}_6$  Aq. Sol. in  $\text{NH}_4$  Aq, but not in  $\text{NH}_4$  salt solution. **Cupric ferricyanide**  $\text{Cu}_2(\text{FeCy})_6$ ; yellowish pp. formed when a cupric salt solution is added by  $\text{K}_2\text{FeCy}_6$ ; said always to contain excess of  $\text{K}_2\text{FeCy}_6$ , possibly in combination; sol.  $\text{NH}_4$  Aq, also in solutions of  $\text{NH}_4$  salts (Wittstein, *Z.* *P.* 63, 314; Williamson, *A.* 57, 225).

**Iron ferricyanides**. **Turnbull's blue**,  $\text{Fe}_3\text{Cy}_{12}$ , is probably ferrous ferricyanide  $\text{Fe}_3(\text{FeCy})_6$ . **Soluble Prussian blue**,  $\text{KFe}_3\text{Cy}_{12}$ , is probably potassium-ferrous ferricyanide,  $\text{FeK}_3\text{FeCy}_{12}$ ; there is also a corresponding  $\text{NH}_4$  salt. **Pelouze's green** (or Prussian green),  $\text{Fe}_3\text{Cy}_{30}$ , may be regarded as ferrous-ferrie ferricyanide,  $\text{Fe}^{II}_3\text{Fe}^{III}_3(\text{FeCy})_6$ .

Addition of  $\text{FeCl}_3$  Aq to  $\text{K}_2\text{FeCy}_6$  Aq produces soluble Prussian blue, which is generally regarded as a ferricyanide; the same compound is produced by adding  $\text{FeSO}_4$  Aq to  $\text{K}_2\text{FeCy}_6$  Aq. The formation of a ferricyanide from the reaction between a ferrous salt and a ferricyanide, and also from that between a ferric salt and a ferrocyanide, is explained by Skraup's observation, that ferrous salts reduce ferricyanides to ferrocyanides, while ferric salts oxidise ferro- to ferri-cyanides (*W. A. B. [Juniheft, 1876] vol. 74, part 2*). When soluble Prussian blue is treated

with  $\text{FeSO}_4$  Aq Turnbull's blue,  $\text{Fe}_3(\text{FeCy})_6$ , is formed; when ferric sulphate is used the product is Prussian blue, which is ferric ferrocyanide  $\text{Fe}_3(\text{FeCy})_6$ . Ferrous ferrocyanide  $\text{Fe}_2\text{FeCy}_6$  (q. v. p. 334), when partially oxidised, produces ferrous ferricyanide (Turnbull's blue), and when more fully oxidised ferric ferrocyanide (Prussian blue) is formed. These reactions suffice to show how easy is the passage from ferrocyanides of iron (both ferrous and ferric salts) to ferricyanides, and *vice versa*.

**Ferrous ferricyanide**  $\text{Fe}_2(\text{FeCy})_6$ . (Turnbull's blue). Obtained by adding  $\text{K}_2\text{FeCy}_6$  Aq to an excess of a ferrous salt, digesting the pp. for some time with the ferrous solution, and washing with hot water; also obtained by partial oxidation of ferrous ferrocyanide  $\text{Fe}_2\text{FeCy}_6$ , which is the pp. formed by adding  $\text{H}_2\text{FeCy}_6$  Aq to a ferrous salt. Best prepared by ppg. excess of a ferrous salt by  $\text{H}_2\text{FeCy}_6$  Aq (q. v.). When dried in air retains about 28 p.c. water (Williamson, *A.* 57, 225); cannot be completely dehydrated without partial decomposition, giving  $\text{Fe}_2\text{O}_3$  and Prussian blue,  $\text{Fe}_3(\text{FeCy})_6$ . Oxidises when moist by exposure to air to ferric ferrocyanide (Prussian blue). Deep-blue powder, with tinge of copper-red; insol. water, alcohol, and dilute mineral acids; sol.  $\text{H}_2\text{C}_2\text{O}_4$  Aq. Decomposed by  $\text{KOH}$  Aq or  $\text{K}_2\text{CO}_3$  Aq, giving  $\text{K}_2\text{FeCy}_6$  Aq and  $\text{Fe}_2\text{O}_3$ ; Prussian blue gives  $\text{Fe}_2\text{O}_3$  and  $\text{K}_2\text{FeCy}_6$  Aq.

**Ferroso-ferrie ferricyanide**  $\text{Fe}^{III}_2\text{Fe}^{II}_2(\text{FeCy})_6 = \text{Fe}_4\text{Cy}_{30}$ . (Prussian green. Pelouze's green) (Pelouze, *A. Ch.* [2] 69, 40; Erlenmeyer, *Lehrb. der organ. Chemie* [1867], p. 48 et seq.; Williamson, *A.* 57, 225). Green pp. obtained by passing excess of Cl into  $\text{K}_2\text{FeCy}_6$  or  $\text{K}_3\text{FeCy}_6$ , boiling the liquid, washing the pp. with conc. boiling  $\text{HCl}$  Aq (to remove  $\text{Fe}_2\text{O}_3$  and Prussian blue) so long as the liquid is turned blue on addition of water, washing with water, and drying. Also produced by prolonged contact of  $\text{K}_2\text{FeCy}_6$  with aqueous acids; and by boiling soluble Prussian blue (K-ferrous ferricyanide,  $\text{FeK}_3\text{FeCy}_{12}$ ) with  $\text{HNO}_3$  Aq. Changed to Prussian blue,  $\text{Fe}_3(\text{FeCy})_6$ , by prolonged contact with air. Heated to  $180^\circ$  gives off Cy and  $\text{HCy}$ . Decomposed by  $\text{KOH}$  Aq, giving  $\text{Fe}_2\text{O}_3$  and  $\text{K}_2\text{FeCy}_6$  Aq and  $\text{K}_2\text{FeCy}_6$ .

Another cyanide of iron, which is probably a ferrous-ferrie ferricyanide, viz.  $\text{Fe}_3\text{Cy}_{18} = \text{Fe}^{II}_2\text{Fe}^{III}_1(\text{FeCy})_6$ , is described by Reynolds (*C. J. Trans.* 1888, 767) as a black solid, formed by heating to boiling 40 parts of bromine in a flask with a reversed condenser for 5 or 6 hours, washing with dilute  $\text{HCl}$  Aq, then thoroughly with cold water, and drying over  $\text{H}_2\text{SO}_4$  *in vacuo*. The substance is hygroscopic; potash decomposes it to  $\text{FeO}$ ,  $\text{H}_2$ ,  $\text{K}_2\text{FeCy}_6$ , and  $\text{K}_2\text{FeCy}_6$ ; it dissolves in conc.  $\text{HCl}$  Aq after long digestion, giving  $\text{FeCl}_3$  and  $\text{FeCl}_2$ ; when moist it is changed in air to Prussian blue.

Double ferricyanides derived from ferrous ferricyanides.

**Ammonium-ferrous ferricyanide**  $\text{NH}_4\text{Fe}_2\text{FeCy}_{12} \cdot 1\frac{1}{2}\text{H}_2\text{O}$  (Wyrubow, *A. Ch.* [5] 8, 444). Corresponds with, and prepared in manner similar to, the K salt (v. post), but more stable than that salt; may be dried without decomposition; not ppd. from solutions by alcohol.

**Potassium ferrous ferricyanide**  $KFe^{II}Fe^{III}Fe(Cy)_6$  (Soluble Prussian blue.) This salt may perhaps be better regarded as potassium-ferric ferrocyanide  $KFe^{III}Fe(Cy)_6$ . It is obtained by mixing  $FeCl_2$  and  $K_2Fe^{III}Fe(Cy)_6$  in the ratio  $FeCl_2 : K_2Fe^{III}Fe(Cy)_6$ ; solutions of known strength of the reacting salts are poured simultaneously into the same vessel with constant stirring, the pp. is at once washed with cold water, and dried over  $H_2SO_4$  in *vacuo* (Skraup, *W. A. B. [Jahrbuch]*, 1876) 74, 2nd part). It is also formed by dissolving about 80 g.  $K_2Fe^{III}Fe(Cy)_6$  in water, and adding about 3 g.  $FeSO_4 \cdot 7H_2O$ , free from ferric salt, dissolved in water; the pp. is washed with air-free water containing a little  $KCl$ , and then with pure water (Skraup, *l.c.*). Dried in *vacuo* the salt has the composition  $2(KFe^{III}Fe(Cy)_6) \cdot 3H_2O$  (Skraup, *l.c.*). (For preparation v. also Brucke, *J.* 1866, 288; Kündel, *D. P. J.* 190, 396).

A blue solid, sol. cold water, solution is decomposed by boiling with formation of yellowish pp. Addition of salts, mineral acids, or alcohol, to the aqueous solution of this compound produces a blue pp. After continued washing with alcohol, soluble blue becomes insol. in water (Skraup, *A.* 186, 371). From an aqueous solution of soluble blue, containing a little alkali, ferric salts ppt. Prussian blue,  $Fe_4(Fe^{III}Fe(Cy)_6)_3$ , and ferrous salts ppt. Turnbull's blue  $Fe_3(Fe^{II}Fe(Cy)_6)_2$  (Skraup, *l.c.*). Alkalies,  $NH_4Aq$ , and alkali carbonates ppt.  $Fe_2O_3 \cdot H_2O$ , and form a solution of ferrocyanide. Digested with  $K_2Fe^{III}Fe(Cy)_6$ ,  $K_2Fe^{III}Fe(Cy)_6$ , and potassium ferrous ferrocyanide ( $K_2Fe^{II}Fe^{III}Fe(Cy)_6$ ) are produced.

The blue compound obtained by Williamson (*A.* 57, 225) by heating potassium ferrous ferrocyanide,  $K_2Fe^{II}Fe(Cy)_6$ , with dilute  $HNO_3$  appears to be identical with soluble Prussian blue. This body was prepared by digesting 1 pt. white  $K_2Fe^{II}Fe(Cy)_6$  with 1 pt. conc. acid and 20 pts. water; when the liquid was nearly boiling  $NO$  escaped, and the lamp was removed; treatment with  $HNO_3$  was continued until a sample of the blue compound produced gave pure  $Fe_2O_3 \cdot H_2O$ , unmixed with  $Fe_2O_3$ , when decomposed by  $KOH$  *Aq*.

**Lead ferricyanide.** Gmelin gives the formula  $Pb_3(Fe^{III}Fe(Cy)_6)_2$ ; Schuler (*W. A. B.* 77, 692) gave  $Pb_2(Fe^{III}Fe(Cy)_6)_2 \cdot 4H_2O$ ; v. Zepharovich (*W. A. B.* 59 [2nd part], 800)  $Pb_2(Fe^{III}Fe(Cy)_6)_2 \cdot 16H_2O$ . According to Wyrubow (*A. Ch.* [5] 10, 413) the salt with  $16H_2O$  is obtained by mixing hot solutions of equivalent weights of  $Pb(NO_3)_2$  and  $K_2Fe^{III}Fe(Cy)_6$ , and allowing to cool. Small dark-reddish crystals; not e. sol. water. Double salts;  $PbK_2Fe^{III}Fe(Cy)_6 \cdot 3H_2O$  (Wyrubow, *l.c.*). The mother-liquor from  $Pb_2(Fe^{III}Fe(Cy)_6)_2$  deposits this salt on cooling. Red, six-sided triclinic plates;  $a:b:c = 1.7205:1.9309$ . Decomposes on exposure to air.  $Pb_2(Fe^{III}Fe(Cy)_6)_2 \cdot 3PbO \cdot 11.111H_2O$ ;  $Pb_2(Fe^{III}Fe(Cy)_6)_2 \cdot Pb(NO_3)_2 \cdot 12H_2O$  (Schuler, *W. A. B.* 77, 692).

**Magnesium ferricyanide**  $Mg_2(Fe^{III}Fe(Cy)_6)_2$ ; reddish brown, non-crystallisable; obtained by treating  $Mg_2Fe^{III}Fe(Cy)_6$  (*q. v.*) with  $Cl$  (Bette, *A.* 23, 115). Reindol (*J. pr.* 103, 166) obtained the double salt  $MgK_2Fe^{III}Fe(Cy)_6$ .

**Manganese ferricyanide**  $Mn_2(Fe^{III}Fe(Cy)_6)_2$ ; brownish pp. by adding  $K_2Fe^{III}Fe(Cy)_6$  to solution of a  $Mn$  salt (Wittstein, *R. P.* 63, 314).

**Nickel ferricyanide**; pp. formed by adding  $K_2Fe^{III}Fe(Cy)_6$  to solution of a  $Ni$  salt is probably  $Ni_2(Fe^{III}Fe(Cy)_6)_2$  (*Gm.* 7, 500). According to Reynoso (*A. Ch.* [3] 30, 252) addition of  $K_2Fe^{III}Fe(Cy)_6$  to an ammoniacal solution of a  $Ni$  salt produces a yellow pp. of the double salt  $Ni_2(Fe^{III}Fe(Cy)_6)_2 \cdot 4NH_3 \cdot 11H_2O$ .

**Potassium ferricyanide**  $K_2Fe^{III}Fe(Cy)_6$  (Red prussiate of potash).

**Formation.**—1. By adding  $PbO_2$  to  $K_2Fe^{III}Fe(Cy)_6$ , and neutralising the  $KOH$  produced by an acid (Seuberlich, *D. P. J.* 238, 484).—2. By adding  $BrAq$  to  $K_2Fe^{III}Fe(Cy)_6$  until  $FeCl_3Aq$  ceases to give blue pp.—3. By passing ozonised  $O$  into  $K_2Fe^{III}Fe(Cy)_6$ .—4. By electrolysis  $K_2Fe^{III}Fe(Cy)_6$  (Schlagdenhauffen, *J.* 1863, 305).

**Preparation.**—1.  $K_2Fe^{III}Fe(Cy)_6$  is digested with potassium-ferrous ferrocyanide,  $K_2Fe^{II}Fe^{III}Fe(Cy)_6$  (*q. v.* p. 334) the liquid is filtered and crystallised (Williamson, *A.* 67, 225).—2. Well washed  $Cl$  is passed into cold  $K_2Fe^{III}Fe(Cy)_6$ , with constant agitation, until a few drops of the liquid give a brown-red colour, but no pp., with  $FeCl_3Aq$ ; the liquid is evaporated, and the crystals are repeatedly recrystallised from water [ $K_2Fe^{III}Fe(Cy)_6 + Cl = KClAq + K_2Fe^{III}Fe(Cy)_6$ ] (Gmelin, *S.* 34, 325; Zimmermann, *D. P. J.* 127, 211). If the passage of  $Cl$  is continued too long some Prussian green is formed (*v. Ferroso-ferric ferricyanide*, p. 338); to remove this, Posselt (*A.* 42, 170) evaporates to the crystallising point, then adds 3 or 3 drops of  $KOH$  *Aq* (not more), filters from  $Fe_2O_3 \cdot H_2O$ , and allows the liquid to crystallise.—3. Bhien (*D. P. J.* 206, 151) recommends to mix  $HClAq$  with cold  $K_2Fe^{III}Fe(Cy)_6$  in the ratio  $2K_2Fe^{III}Fe(Cy)_6 : HCl$ , and then to add a cold filtered solution of bleaching powder until  $FeCl_3Aq$  gives no blue pp.; any excess of acid is then neutralised by  $CaCO_3$ , and the solution is evaporated to the crystallising point. The first crop of crystals is pure, the subsequent crops contain traces of lime which may be removed by re-crystallisation.

**Properties.**—Large red prismatic crystals; monoclinic,  $a:b:c = 7157:1:5985$  (Kopp, *Krystallographie*, 311); according to Schabus (*W. A. B.* 1850, 582) the crystals are trimetric with the ratio of axes  $a:b:c = 1.2418:1.6706:1$ . *S.G.* 1.8–1.85 (Schabus, *l.c.*; Wallace, *C.* 2, 7, 77). *S.* 33 at  $4.5^\circ$ ,  $36.6$  at  $10^\circ$ ,  $39.1$  at  $15.5^\circ$ ,  $58.7$  at  $38^\circ$ ,  $77.5$  at  $100^\circ$ ,  $81.9$  at  $104^\circ$  (= B.P. of saturated solution) (Wallace, *l.c.*). *S.G.* of  $K_2Fe^{III}Fe(Cy)_6$  saturated at  $15.5^\circ = 1.178$  (Schiff, *A.* 113, 199). Nearly insol. alcohol. *H.F.* [ $K$ ,  $Fe$ ,  $Cy$ ] = 278,700; data obtained by oxidising  $K_2Fe^{II}Fe^{III}Fe(Cy)_6$  by  $Cl$  and  $Br$ , also  $H_2Fe^{III}Fe(Cy)_6$  by  $Br$ , and reducing  $Zn_2(Fe^{III}Fe(Cy)_6)_2$  by  $HIAq$  (Joannis, *C. R.* 94, 449, 541, 725).

**Reactions.**—1. Heated in a closed vessel, decrepitates, evolves  $Cy$  and a little  $N$ , residue consists of  $KCy$ ,  $K_2Fe^{III}Fe(Cy)_6$ ,  $Fe_2(Fe^{III}Fe(Cy)_6)_3$ ,  $C$ ,  $Fe$ , and probably paracyanogen. Heated in air,  $Cy$  is evolved and  $Fe_2O_3$  and  $KCy$  remain.—2.  $K_2Fe^{III}Fe(Cy)_6$  is reduced to  $K_2Fe^{II}Fe^{III}Fe(Cy)_6$  by the action of sunlight (not by yellow light) (Vogel, *B.* 4, 90; Schönbein, *P.* 67, 87); also reduced by  $H_2S$  (Williamson, *A.* 57, 252); by alkali sulphide (Liesching, *D. P. J.* 128, 206); by thiosulphates (Diehl, *J. pr.* 79, 430; cf. Löwe, *J.* 1857, 273); by  $HI$  (Lennsen, *A.* 91, 240); by reduced  $Ag$ ,  $Zn$ ,  $Fe$ ,  $Bi$ , &c. (Eder, *J. pr.* [2] 16, 211; Böttger, *C. C.* 1872, 708); by ferrous salts when hot (Skraup

A. 186, 371); by  $\text{H}_2\text{O}_2$  in alkaline solution (Weltzien, A. 138, 129); also by  $\text{SO}_2$  in alkaline solution (Weltzien, A. 138, 129); also by many organic reducing agents, e.g. formic acid (Schönbein, P. 67, 87). — 3. Alkaline solution of  $\text{K}_2\text{FeCy}_6$  acts as an oxidiser, e.g., towards sugar, starch, alcohol, oxalic acid (Wallace, C. J. 7, 77), indigo (Mercer, P. M. [3] 31, 126); NO is oxidised to  $\text{HNO}_3$ , P to  $\text{H}_3\text{PO}_4$ , and S is said to be oxidised to  $\text{H}_2\text{SO}_4$  (Wallace, *loc. cit.*). — 4. *Ammonia* reacts with  $\text{K}_2\text{FeCy}_6$  to form  $\text{K}_4\text{FeCy}_6(\text{NH}_3)_4$ , and N (Moulières, J. Ph. [3] 11, 254). — 5. *Potash* when boiled down with conc.  $\text{K}_2\text{FeCy}_6$  produces  $\text{K}_4\text{FeCy}_6$  and  $\text{KC}_y$ , evolving Cy and pp.  $\text{Fe}_2\text{O}_3$  (Boudault, J. Ph. [3] 7, 437). — 6. Some *oxidisable metallic oxides*, e.g.  $\text{PbO}$ ,  $\text{Cr}_2\text{O}_3$ ,  $\text{MnO}$ ,  $\text{SnO}$ , when boiled with  $\text{K}_2\text{FeCy}_6$  in presence of  $\text{KOH}$ , form  $\text{K}_4\text{FeCy}_6$ , and a higher oxide of the metal;  $\text{CoO}$  and  $\text{NiO}$  are not thus oxidised; salts of Ag and Au produce  $\text{Fe}_2\text{O}_3$  with solution of  $\text{K}_2\text{FeCy}_6$ , and double cyanide of K and Ag, or K and Au. — 7. When *mercuric oxide* is boiled with  $\text{K}_2\text{FeCy}_6$ ,  $\text{HgCy}_6$  is formed, and the whole of the Fe is ppd. as  $\text{Fe}_2\text{O}_3$  (Gmelin). — 8.  $\text{K}_2\text{FeCy}_6$  is decomposed by excess of *chlorine* with production of  $\text{HCy}$  and  $\text{CyCl}$ ; on boiling, or on addition of alkali, the liquid deposits *ferroso-ferrie ferricyanide*  $\text{Fe}_3^{11}\text{Fe}^{12}(\text{FeCy}_6)_4$  (q. v. p. 338). Bromine, in excess, and with prolonged action, produces Prussian blue; when the action is continued for a shorter time a black cyanide of  $\text{Fe}_3^{11}\text{Fe}_2^{12}(\text{FeCy}_6)_4$ , probably a ferroso-ferrie compound  $\text{Fe}_3^{11}\text{Fe}_2^{12}(\text{FeCy}_6)_4$ , is formed (q. v. p. 338); when the ferricyanide is in excess Turnbull's blue is produced (Reynolds, C. J. Trans. 1888, 767). — 9. *Nitric acid* produces nitroprusside of potassium (q. v. p. 341) and nitre (Playfair, P. M. [3] 26, 197, 271, 348). — 10. *Hydrochloric acid* when boiled with  $\text{K}_2\text{FeCy}_6$ , forms  $\text{HCl}$ ,  $\text{FeCl}_3$ , and *Turnbull's blue*,  $\text{Fe}_3(\text{FeCy}_6)_4$ . — 11. *Nitric oxide* produces K nitroprusside (Bunge, Z. 1866, 82).

**Combination.** — With *potassium iodide* to form  $\text{K}_2\text{FeCy}_6\text{KI}$ ; very unstable salt (Preuss, A. 29, 323; Mohr, A. 105, 57; Blomstrand, J. pr. [2] 3, 207; cf. Kern, C. N. 33, 184).

The double salts  $\text{KNa}_2\text{FeCy}_6$ ,  $\text{KNa}_4(\text{FeCy}_6)_2$ ,  $\text{K}_2\text{NaFeCy}_6$ , have been isolated (v. Reindel, J. pr. 102, 43; *ibid.* Z. 1870, 147; Laurent, J. 1849, 291; Wyrubow, Bl. [2] 12, 98; 14, 145).

**Silver ferricyanide**  $\text{Ag}_3\text{FeCy}_6$ . Orange yellow salt obtained by adding  $\text{K}_2\text{FeCy}_6$  to  $\text{AgNO}_3$  solution. When freshly ppd.  $\text{Ag}_3\text{FeCy}_6$  is treated with  $\text{NH}_4\text{Aq}$ , or when  $\text{K}_2\text{FeCy}_6$  is added to  $\text{AgNO}_3$  solution with enough  $\text{NH}_4\text{Aq}$  to form a clear liquid, a reddish pp. of the double salt  $2\text{Ag}_3\text{FeCy}_6 \cdot 3\text{NH}_3 \cdot 4\text{H}_2\text{O}$  is produced (Gintl, W. A. B. 59, 554). This compound dissolves in excess of  $\text{NH}_4\text{Aq}$ , and on heating decomposes, giving  $(\text{NH}_4)_3\text{FeCy}_6$ ,  $\text{NH}_4\text{Aq}$ ,  $\text{Ag}_2\text{FeCy}_6$ , and N.

**Sodium ferricyanide**  $\text{Na}_3\text{FeCy}_6$ . Ruby-coloured deliquescent prisms; obtained by oxidising  $\text{Na}_2\text{FeCy}_6$  by Cl and evaporating. S. 15-9 cold water, 80 at  $100^\circ$  (Bette, A. 23, 115; Reindel, J. pr. 102, 43; Krämer, J. Ph. 15, 98).

**Tin ferricyanides**; *stannous ferricyanide*  $\text{Sn}_2(\text{FeCy}_6)_3$ , gelatinous pp. by adding  $\text{K}_2\text{FeCy}_6$  to  $\text{SnCl}_2$  solution. Wyrubow (A. Ch. [5] 8, 444) gives the formula  $\text{Sn}_2(\text{FeCy}_6)_3 \cdot 25\text{H}_2\text{O}$ .

**Ferricyanides of uranium, vanadium, and**

**zinc probably exist, but there is little accurate knowledge regarding them.**

**NITROPRUSSIDES (Nitroprussiates. Nitro ferricyanides.)** Salts of *nitroprussic acid*  $\text{H}_2\text{FeC}_4\text{N}_6\text{O}$  (probably  $\text{H}_2\text{FeCy}_5\text{NO}$ ). These salts were discovered by Playfair in 1850 (P. M. [3] 36, 197, 271, 348). They have been studied by Gerhardt, Hadow, Roussin, and others, but their constitution cannot be regarded as finally determined. The nitroprussides are formed by reactions between nitric acid and the alkali ferro- or ferri-cyanides, or between ferro- or ferri-cyanhydric acid and nitric oxide, or by adding  $\text{KNO}_3$  and a dilute acid to a ferrocyanide. The first products of the reaction between  $\text{K}_2\text{FeCy}_6$  and  $\text{HNO}_3$  are  $\text{K}_2\text{FeCy}_5\text{NO}$  and NO; these then react to produce K nitroprusside with evolution of  $\text{HCy}$ , N, and  $\text{CO}_2$ . According to Jensen (J. Ph. [5] 11, 315) continued electrolysis of  $\text{K}_2\text{FeCy}_6$  produces a liquid which gives the reactions of K nitroprusside. By boiling a mixture of  $\text{FeCl}_3$  and  $\text{KC}_y$ , to which  $\text{KNO}_3$  has been added, K nitroprusside is formed; according to Roussin (A. Ch. [3] 52, 285) this process is analogous to that whereby *iron nitrosulphide* (q. v. under Iron) is produced,  $\text{K}_2\text{S}$  being used in place of  $\text{KC}_y$ . Alkali nitroprussides are soluble in water; the insoluble salts, e.g. of Cu, Fe, Zn, are obtained from these by double decomposition; the Fe or Cu salt decomposed by  $\text{NH}_4\text{Aq}$ ,  $\text{CaO}$ , or  $\text{BaO}$ , gives a solution of the  $\text{NH}_4$ , Ca, or Ba nitroprusside. The nitroprussides are generally coloured and crystallise well. A solution of a nitroprusside gives a deep brilliant purple colour with an alkali sulphide; the colour soon fades; this reaction is used as a very delicate test for nitroprussides. The nitroprussides are decomposed by boiling with alkalis, giving  $\text{Fe}_2\text{O}_3$ , N, alkali ferrocyanide, and probably alkali nitrite. With  $\text{H}_2\text{S}$  they give  $\text{Fe}_2\text{O}_3$ , Prussian blue, S, a ferrocyanide, and a nitrosulphide of Fe; they are not usually changed by  $\text{SO}_2$ , sulphites, or thiosulphates, but are decomposed by hot conc.  $\text{H}_2\text{SO}_4$ . Some of these salts are stable; others undergo change in solution with ppn. of Prussian blue or  $\text{Fe}_2\text{O}_3$ .

The constitution assigned by Gerhardt to the nitroprussides (*Traité*, 1, 344) was  $\text{M}_2\text{FeCy}_5\text{NO}$

$[\text{M} = \text{K}, \text{Ca}, \&c.]$  which represents the com-

pounds as salts of a dibasic acid containing the groups NO and Cy in combination with Fe. The reaction between ferricyanhydric acid and nitric oxide is represented thus:  $\text{H}_2\text{FeCy}_6 + \text{NO} = \text{H}_2\text{FeCy}_5\text{NO} + \text{HCy}$ . Hadow (C. J. [2] 4, 341) supposed that the nitroprussides contained the group  $\text{N}_2\text{O}_2$ , because  $\text{NO}_2$  does not change  $\text{K}_2\text{FeCy}_6$  acidulated with  $\text{H}_2\text{SO}_4$ , whereas nitroprusside is formed by passing the gas evolved by heating starch with nitric acid into  $\text{K}_2\text{FeCy}_6$ . Städeler (Z. 5, 559) represents the preparation of K nitroprusside by the action of nitric acid on  $\text{K}_2\text{FeCy}_6$  (Playfair's method) by the following equations (supposing that  $\text{H}_2\text{FeCy}_6$  is first formed) (B)  $2\text{H}_2\text{FeCy}_6 + \text{HNO}_3 = 2\text{H}_2\text{FeCy}_5\text{Aq} + \text{HNO}_2\text{Aq} + \text{H}_2\text{O}$ ;

(2)  $2\text{H}_2\text{FeCy}_6 + 2\text{HNO}_3 = 2\text{H}_2\text{FeCy}_5(\text{NO}) + 2\text{H}_2\text{O} + \text{Cy}_2$ .

Regarding constitution of nitroprussides v. Kyd (A. 74, 340), Weith (Z. [2] 4, 104).

**Nitroprussic acid**  $\text{H}_2\text{FeC}_5\text{N}_3\text{O}_6\text{H}_2\text{O}$ ; probably  $\text{H}_2\text{FeCy}_3\text{N}_3\text{O}_6\text{H}_2\text{O}$  (*Nitroferri-cyanic acid*, *Nitroferri-cyanhydric acid*). Obtained by decomposing the Ag salt by an equivalent quantity of  $\text{HClAg}$ , or the Ba salt by an equivalent of  $\text{H}_2\text{SO}_4\text{Ag}$ , filtering, and evaporating *in vacuo*. Dark red deliquescent crystals; very easily decomposed in solution with formation of  $\text{HCy}$  and  $\text{Fe}_2\text{O}_3$  (Playfair, *l.c.*).

**Ammonium nitroprusside**  $(\text{NH}_4)_3\text{FeC}_5\text{N}_3\text{O}_6$ . Obtained by decomposing the Fe salt by  $\text{NH}_4\text{Ag}$ , filtering and evaporating gently. Very unstable; solution deposits Prussian blue when boiled (Playfair).

**Barium nitroprusside**  $\text{BaFeC}_5\text{N}_3\text{O}_6 \cdot 3\text{H}_2\text{O}$ . Obtained similarly to the  $\text{NH}_4$  salt. Dark red, very soluble, quadric crystals; give off most of their  $\text{H}_2\text{O}$  at  $100^\circ$  (P.).

**Calcium nitroprusside**  $\text{CaFeC}_5\text{N}_3\text{O}_6 \cdot 4\text{H}_2\text{O}$ ; very soluble, easily decomposed crystals (P.).

**Copper nitroprusside**  $\text{CuFeC}_5\text{N}_3\text{O}_6 \cdot 2\text{H}_2\text{O}$ ; greenish pp. becoming grey on exposure to light; produced by adding solution of the K or Na salt to solution of a Cu salt (P.).

**Iron nitroprusside (ferrous)**. Yellowish pink pp. by adding  $\text{K}_2\text{FeC}_5\text{N}_3\text{O}_6\text{Ag}$  to a ferrous salt; ferric salts give no pp. Decomposed by alkalis. Probably  $\text{FeFeC}_5\text{N}_3\text{O}_6$  (P.).

**Potassium nitroprusside**  $\text{KFeC}_5\text{N}_3\text{O}_6 \cdot 2\text{H}_2\text{O}$  (P.; also Euz, *Vierteiljahr. Pharm.* 2, 239). Prepared similarly to the sodium salt (*q. v.*). Dark red monoclinic crystals. S. c.  $100$  at  $16^\circ$ ; sol. alcohol. Very deliquescent; solution slowly deposits Prussian blue. The basic salt  $\text{KFeC}_5\text{N}_3\text{O}_6 \cdot \text{KOH} \cdot \text{H}_2\text{O}$  is obtained by mixing a solution of the normal salt with twice its volume of alcohol, and then adding potash. Jensen (*J. Ph.* 15) 11, 315) prepared the salt by reacting on  $\text{K}_2\text{FeCy}_3$  with Ca hypochlorite solution.

**Silver nitroprusside**  $\text{Ag}_3\text{FeC}_5\text{N}_3\text{O}_6$ . Flesh-coloured pp. obtained from the Na or K salt by adding  $\text{AgNO}_3\text{Ag}$ ; insol. water, alcohol, or  $\text{HNO}_3\text{Ag}$  (P.).

**Sodium nitroprusside**  $\text{NaFeC}_5\text{N}_3\text{O}_6 \cdot 2\text{H}_2\text{O}$ . The other nitroprussides are made from this salt.

**Preparation.**—Four parts powdered  $\text{K}_2\text{FeCy}_3$  are mixed with c. 51 parts nitric acid S.G. 1.36, the conc. acid being diluted with its own volume of water. The acid is poured on to the salt in one quantity; the lowering of temperature is sufficient to moderate the reaction. The salt dissolves forming a coffee-coloured liquid, and evolving  $\text{CO}_2$ , N, Cy, and  $\text{HCy}$ ; the liquid is placed in a large flask, and warmed on the water-bath so long as gases are evolved, and until the liquid gives a dark green or slate-coloured\* pp., instead of a blue pp., with a ferrous salt; on cooling, crystals of  $\text{KNO}_3$  mixed with a little oxamide are deposited; the mother-liquor is neutralised by  $\text{Na}_2\text{CO}_3$  (if  $\text{K}_2\text{CO}_3$  is used, K nitroprusside is obtained) and boiled; it is then filtered, and evaporated at c.  $40^\circ$ , or better *in vacuo*, until crystallisation begins on cooling; the  $\text{KNO}_3$  separates, and the mother-liquor yields the nitroprusside which is purified by recrystallisation from water, the prismatic crystals which form being removed from the hot liquid, dissolved in a little hot water, and allowed to crystallise by

cooling (in this way the  $\text{KNO}_3$  is separated) (P.; cf. Weith, *A.* 147, 312; Overbeck, *Ar. Ph.* [2] 72, 270; Roussin, *J.* 1852, 438; Schafarik, *W. A. B.* 47, 262).

**Properties and Reactions.**—Large ruby-red trielmic\* prisms; non-deliquescent. S. c.  $40$  at  $15^\circ$ . Does not lose water at  $100^\circ$  (P.; also Rammelsberg, *P.* 87, 107). 1. Aqueous solution decomposes rapidly in sunlight or on heating with ppn. of Prussian blue (Roussin, *J.* 1853, 309).—2. *Electrolysis* also produces Prussian blue (Schlagdenhanff, *J.* 1863, 305; Weith, *A.* 147, 312).—3. An *alkaline solution* acts as an energetic oxidiser (Stadel, *A.* 151, 1).—4. *Boiled with alkalies*  $\text{Fe}_2\text{O}_3\text{H}_2$  is ppd., N evolved, and the solution contains a nitrite and a ferrocyanide.—5. *Sulphuretted hydrogen* ppt. S and Prussian blue, and  $\text{Na}_2\text{FeCy}_3$  remains in solution.—6. *Sodium amalgam*, in presence of acetic acid, produces a yellow colour, and alcohol causes a pp. in this liquid (for details v. Weith, *A.* 147, 312). 7. Oxidised to  $\text{NaNO}_3$ , and  $\text{Na}_2\text{FeCy}_3$  by *potassium permanganate* in alkaline solution (Weith, *l.c.*). 8. Decomposed by *chlorine* when heated with it, or when exposed to sunlight (Davy, *C. N.* 38, 105).—9. Decomposed by *bromine* at temperatures above  $100^\circ$  (Weith, *l.c.*).—10. Easily decomposed by conc. *sulphuric acid*.—11. With *soluble metallic sulphides*, including  $\text{NH}_4$  sulphide, a deep purple colour is produced; the liquid soon becomes turbid, and ppts. S and  $\text{Fe}_2\text{O}_3$ , while  $\text{NaNO}_3$ ,  $\text{Na}_2\text{FeCy}_3$ , and  $\text{NaSCy}$  remain in solution. If an alcoholic solution is used the coloured body separates in oily drops, which give a green powder when dried *in vacuo* (Playfair).

**Zinc nitroprusside**  $\text{ZnFeC}_5\text{N}_3\text{O}_6$ . Yellow-rose pp. by adding  $\text{KFeC}_5\text{N}_3\text{O}_6\text{Ag}$  to solution of a Zn salt.

**PERFERROCYANIDES.**—When  $\text{K}_2\text{FeCy}_3\text{Ag}$  is heated with I a greenish-brown liquid is formed, from which alcohol ppts. a crystalline salt; this salt dissolves in water forming a dark reddish violet liquid (Stadel, *A.* 151, 1). The salt is better prepared by mixing powdered  $\text{K}_2\text{FeCy}_3$  with  $\text{KClO}_4$ , adding  $\text{HClAg}$ , heating very gently, neutralising by  $\text{Na}_2\text{CO}_3$  after disengagement of gas has ceased, evaporating, ppg. by alcohol, and again dissolving in water and ppg. by alcohol (Boug, *Bl.* [2] 21, 268; Skraup, *A.* 189, 368). The salt is nearly black; it dissolves in water, is deep violet; the compound is very unstable, soon giving off Cy; even in the dark it changes colour to greenish black, and then dissolves to form a green solution. Boiled with water it forms  $\text{K}_2\text{FeCy}_3\text{Ag}$  and  $\text{Fe}_2(\text{OH})_6$ . An aqueous solution of this salt gives green pps. with many metallic salts; it acts as an energetic oxidiser. Nitric acid forms K nitroprusside,  $\text{KFeC}_5\text{N}_3\text{O}_6$ . The salt probably has the composition  $\text{KFeCy}_3$ ; if this is established the relation of potassium perferri-cyanide to potassium ferri-cyanide is similar to that of the ferro- to the ferro-cyanide ( $\text{K}_2\text{FeCy}_3$ ,  $\text{K}_2\text{FeCy}_3$ ,  $\text{KFeCy}_3$ ).

**Lanthanum cyanide**,  $\text{LaCy}_3$  (Frerichs, *Smith*, *A.* 191, 365). A gelatinous pp., formed by adding solution of  $\text{La}_2(\text{SO}_4)_3$  to  $\text{KCyaAg}$ ; forms double cyanides, e.g.  $2\text{LaCy}_3 \cdot 3\text{PbCy}_3 \cdot 18\text{H}_2\text{O}$ .

**Lead cyanides.** No cyanide of Pb has been isolated. Pb salts are not ppd. by  $\text{HCNAg}$ ; but if  $\text{NH}_3$  is present a white pp. of *lead oxy-cyanide*  $\text{PbCy}_2 \cdot 2\text{PbO}$  is obtained (Erlenmeyer, *J. pr.* 48,

356; Kugler, *A. 66*, 63).  $\text{KCyAq}$  added to Pb salts gives a pp. insoluble in excess of  $\text{KCy}$ . Joannis (*C. R.* 93, 271) gives the thermal data [ $\text{Pb}, \text{C}_2\text{N}_2, 2\text{PbO}, \text{H}_2\text{O}$ ] = 17,800 (formation of solid  $\text{PbCy}_2, 2\text{PbO}, \text{H}_2\text{O}$  from gaseous  $\text{Cy}_2$  and other materials as solids). Rammelsberg (*P.* 42, 114) says that addition of  $\text{ZnCy}_2, 2\text{KCyAq}$  to solution of a lead salt ppts.  $\text{PbCy}_2, \text{ZnCy}_2$ . The chlorocyanide  $2\text{PbCy}_2 \cdot \text{PbCl}_2$  is described by Thorp (*Am.* 10, 229) as obtained by digesting  $\text{PbCl}_2$  with  $\text{KCyAq}$ .

**Magnesium cyanide.** Not isolated; solution of  $\text{MgO}$  in  $\text{HCNAq}$  soon decomposes with evolution of  $\text{HCN}$  (v. Schulz, *J. pr.* 68, 257).

**Manganese cyanides.** No simple cyanide of Mn has been certainly isolated (Eaton a. Fittig, *A.* 145, 157). Several compounds are known which are best regarded as salts of *manganocyanhydric acid*  $\text{H}_2\text{MnCy}_2$ , which acid has itself been isolated, and *manganocyanhydric acid*  $\text{H}_2\text{MnCy}_2$ .

**Manganocyanhydric acid**  $\text{H}_2\text{MnCy}_2$ . Obtained by decomposing the Pb salt by  $\text{H}_2\text{S}$ , filtering, and evaporating *in vacuo* over  $\text{H}_2\text{SO}_4$ ; insol. in ether, sl. sol. in alcohol (Descamps, *A. Ch.* [5] 24, 178). The Pb salt is obtained by adding  $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2$  to a freshly-prepared solution of  $\text{K}_2\text{MnCy}_2$ , which is itself formed by adding 10 grams manganous acetate to 40-45 grams  $\text{KCy}$  in 100 c.c. almost boiling water, and then adding 15-20 grams  $\text{KCy}$ , and dissolving the crystals of  $\text{K}_2\text{MnCy}_2$  (which separate on cooling) in water (Christensen, *J. pr.* [2] 31, 163).

**Manganocyanides.**  $\text{K}_2\text{MnCy}_2 \cdot 6\text{H}_2\text{O}$  (for preparation v. *supra*); deep-blue quadric crystals; lose  $6\text{H}_2\text{O}$  over  $\text{H}_2\text{SO}_4$ ; may be crystallised unchanged from a little  $\text{KCyAq}$  (Eaton a. Fittig, *A.* 145, 157; Descamps, *A. Ch.* [5] 24, 178). Freshly-prepared solution of this salt gives pps. with most metallic salts; the following are soluble in water and crystallisable:  $-\text{Ba}_2\text{MnCy}_4$ ;  $\text{BaK}_2\text{MnCy}_4$ ;  $\text{Ca}_2\text{MnCy}_4$ ;  $\text{Na}_2\text{MnCy}_4 \cdot 16\text{H}_2\text{O}$ ;  $\text{Sr}_2\text{MnCy}_4$  (E. a. F., *loc.*; D., *loc.*). Addition of I to  $\text{K}_2\text{MnCy}_2$  ppts. all Mn as hydrioxide (Beilstein a. Jawein, *B.* 12, 1528). According to Descamps (*A. Ch.* [5] 24, 178) passage of NO into manganocyanides produces salts analogous to *nitroprussides* (q. v. p. 340).

**Manganocyanides.**  $\text{K}_2\text{MnCy}_2$  is obtained by allowing solution of  $\text{K}_2\text{MnCy}_2$  in  $\text{KCyAq}$  to oxidise in air (Eaton a. Fittig, *A.* 145, 157); or by adding manganous acetate to warm  $\text{KCyAq}$  until the liquid is deep-red, filtering, and cooling (Christensen, *J. pr.* [2] 31, 163). Reddish-brown needles, isomorphous with  $\text{K}_2\text{FeCy}_2$  (Rammelsberg, *P.* 42, 112; Handl, *W. A. B.* 32, 246). By long boiling with water all Mn is pptd. as hydrioxide. Other manganocyanides described are  $\text{Ba}_2(\text{MnCy}_2)_4$ ,  $\text{Ca}_2(\text{MnCy}_2)_4$ , and  $\text{Na}_2\text{MnCy}_2 \cdot 2\text{H}_2\text{O}$  (Eaton a. Fittig, *A.* 145, 157). The manganocyanides are reduced to manganocyanides by Na-amalgam (Descamps, *A. Ch.* [5] 24, 178).

**Mercury cyanides.** Only one cyanide of Hg is known,  $\text{HgCy}_2$ ; it forms very many double cyanides, and also combines with many other salts to form double compounds. When  $\text{HgO}$  is heated with  $\text{HCNAq}$ ,  $\text{HgCy}_2$  and Hg are formed.

**Mercuric cyanide**  $\text{HgCy}_2$ . Prepared by boiling Prussian blue with  $\text{HgO}$  and water; or by boiling 1 part  $\text{K}_2\text{FeCy}_2$  with 2 parts  $\text{HgSO}_4$  and 8 parts water; or by dissolving  $\text{HgO}$  in slight

excess of  $\text{HCNAq}$  and crystallising. White quadric prisms (De la Provostaye, *A. Ch.* [3] 6, 159; Kopp, *Einführung in d. Kristallog.* p. 163). S.G. 4.0 (Schröder, *B.* 13, 1070). Very poisonous. Sol. in about 8 parts water at ordinary temperature, much more sol. in hot water, insol. in absolute alcohol. When heated gives  $\text{HgCy}_2$  and paracyanogen (Johnston, *A.* 22, 280; Troost a. Hautefeuille, *C. R.* 66, 735, 795). Solution not pptd. by alkalis; but readily decomposed by  $\text{H}_2\text{S}$ , also by  $\text{HClAq}$ ; very slightly decomposed by other dilute acids in the cold (Plugge, *Fr.* 1879, 408). Decomposed by heating with conc.  $\text{H}_2\text{SO}_4$ ; decomposed by Cl, Br, and I, giving  $\text{HgCl}_2$ , &c., and  $\text{CyCl}$ , &c., action of Cl is attended with explosions (Bonis, *A.* 56, 267; 64, 305; Weith, *B.* 6, 1705; Senllas, *A. Ch.* 35, 293; Stenhouse, *A.* 33, 92). H.F. [ $\text{HgCy}_2$ ] = 18,950; [ $\text{HgCy}_2 \cdot \text{Aq}$ ] = -2,970 (*Th.* 3, 512).

**Mercuric oxycyanide**  $\text{HgCy}_2 \cdot \text{HgO}$ . Small needles, formed by dissolving  $\text{HgO}$  in warm  $\text{HgCy}_2$  and crystallising. Very slightly sol. in water; explodes when heated (Johnston, *T.* 1839, 113; Schlieper, *A.* 59, 10; Clarke, *B.* 11, 1504). Joannis (*C. R.* 93, 271) gives the thermal data [ $\text{HgCy}_2 \cdot \text{HgO}$ ] = 2,400.

**Double cyanides containing mercuric cyanide.**  $-\text{HgCy}_2, 2\text{KCy}$ ; obtained as transparent octahedra, unchanged in air, by dissolving  $\text{HgCy}_2$  in hot  $\text{KCyAq}$  and crystallising, or by heating  $\text{HgCy}_2$  with  $\text{HCyAq}$  and  $\text{K}_2\text{CO}_3$  (Gauthier, *A.* 106, 211). I.F. [ $\text{HgCy}_2, 2\text{KCyAq}$ ] = 27,780; [ $\text{HgCy}_2, 2\text{KCyAq}$ ] = 8,830; [ $\text{HgCy}_2 \cdot \text{Aq}, 2\text{KCyAq}$ ] = 11,800 (*Th.* 3, 472). Dissolves in c. 4 parts cold water; solution gives pps. with soluble salts of Zn, Pb, &c., these pps. being double cyanides of Hg and the other metal; the following have been isolated:  $-\text{3HgCy}_2, 2\text{CdCy}_2$  (Schuler, *A.* 87, 46);  $\text{HgCy}_2, \text{HgO}, 7\text{AgCy}$  (Bloxam, *B.* 16, 2669);  $\text{HgCy}_2, \text{N}(\text{CH}_3)_3, \text{Cy}$  (Claus a. Merck, *B.* 16, 2737).

**Double compounds of mercuric cyanide with metallic salts** (Destfosses, *J. Chim. Méd.* 6, 261; Gauthier, *A.* 106, 211; Dexter, *C. C.* 1862, 597; Brett, *P. M.* [3] 12, 235; Poggiale, *C. R.* 23, 762; Liebig, *S.* 49, 253; Weeren, *P.* 93, 461; Clarke, *B.* 11, 1504; Ahlén, *Bl.* [2] 27, 365; Caillot, *A. Ch.* [3] 12, 235; 19, 220; Berthelot, *P.* 22, 620; Kletzensky, *Z.* 1866, 127; Nylander, *J. pr.* 79, 379; Wohler, *P.* 1, 231; Kessler, *P.* 74, 274; Caillot a. Podevin, *J. Ph.* 11, 246; Rammelsberg, *P.* 42, 131; 85, 145; Darby, *A.* 65, 204; Kane, *A.* 35, 356; Bockmann, *A.* 22, 153; Philipp, *P.* 131, 86; Winkler, *Buchner's Report.* 31, 159; Claus a. Merck, *B.* 16, 2737; Custer, *A.* 68, 323; Apjohn, *P. M.* 9, 401).

I. *With chlorides*: with  $\text{NH}_4\text{Cl}$ ,  $\text{BaCl}_2$ ,  $\text{CaCl}_2$ ,  $\text{MgCl}_2$ ,  $\text{SrCl}_2$ ,  $\text{NaCl}$ ,  $\text{MnCl}_2$ ,  $\text{ZnCl}_2$  (Brett, Poggiale); with  $\text{KCl}$  (Destfosses, Gauthier, Dexter); with  $\text{CoCl}_2$ ,  $\text{FeCl}_2$ ,  $\text{NiCl}_2$ ,  $\text{SnCl}_4$  (Poggiale, Dexter); with  $\text{HgCl}_2$  (Poggiale, Liebig, Weeren, Clarke); with chlorides of Ca, Di, Sr, La, and Y (Ahlén).

II. *With bromides*: with  $\text{BaBr}_2$ ,  $\text{SrBr}_2$ ,  $\text{NaBr}$  (Caillot); with  $\text{CaBr}_2$  (Custer); with  $\text{KBr}$  (Brett, Caillot, Berthelot).

III. *With iodides*: with  $\text{CaI}_2$  (Poggiale); with  $\text{BaI}_2$ ,  $\text{SrI}_2$ ,  $\text{NaI}$  (Custer); with  $\text{KI}$  (Apjohn, Caillot, Gauthier, Kletzensky).

IV. *With other metallic salts*: with  $\text{KClO}_4$  (Poggiale); with nitrates of Cd, Cu, Fe, Mn, Ni, Zn (Nylander); with  $\text{AgNO}_3$  (Wöhler, Geu-

ther); with  $\text{HgNO}_3$  (Gauthier); with  $\text{K}_2\text{S}_2\text{O}_8$  (Kessler); with  $\text{K}_2\text{C}_2\text{O}_4$  and  $\text{Ag}_2\text{C}_2\text{O}_4$  (Caillot, A. Pödevin, Rammelsberg, Darby); with  $\text{K}_2\text{FeCy}_4$  (Kane); with sulphocyanides of Ba, Ca, Mg, K (Böckmann, Philipp); with  $\text{H.CO}_2\text{NH}_4$  (Poggiale); with  $\text{H.CO}_2\text{K}$  (Winckler); with  $\text{Na.C}_2\text{H}_3\text{O}_2$  (Custer).

V. With organic ammonium derivatives and alkaloids.  $\text{HgCy}_2$  reacts with  $\text{N}(\text{CH}_3)_4\text{I}$  to form two isomeric compounds: a white salt  $\text{HgCy}_2.\text{N}(\text{CH}_3)_4\text{I}$  and a yellow salt  $\text{HgCy}_2.\text{I.N}(\text{CH}_3)_4\text{Cy}$  (Claus a. Merck).  $\text{HgCy}_2$  forms double compounds with aniline cyanhydride, with iodo-ethyl quinine, iodo-ethyl cinchonidine, and iodo-ethyl strychnine (Claus a. Merck).

**Nickel cyanides.** Only one cyanide of Ni is known,  $\text{NiCy}_2$ ; it forms several double cyanides; neither nickel-cyanides nor nickel-cyanides corresponding to the cobalto- and cobalti-cyanides have been isolated.

**Nickelous cyanide**  $\text{NiCy}_2.x\text{H}_2\text{O}$ . Apple-green pp. obtained by adding  $\text{KCyaq}$  to solution of a Ni salt, or  $\text{HCNAq}$  to Ni acetate solution. Loses all water at  $c. 200^\circ$ ; at higher temperatures decomposes, evolving Cy and N, and leaving Ni and a carbide of Ni. Soluble in excess of  $\text{KCyaq}$  to form  $\text{NiCy}_2.2\text{KCy}$  (Wöhler, *Gehlen's Journ.* 6, 234; Rammelsberg, *P.* 42, 114).

Double cyanides containing nickelous cyanide.  $\text{NiCy}_2.2\text{KCy.H}_2\text{O}$ ; obtained by adding excess of  $\text{KCyaq}$  to solution of a Ni salt, evaporating, and crystallising. Red-yellow monoclinic prisms; S.G. 1.875 at  $11^\circ$ . Loses all water at  $100^\circ$ . Solution decomposes slowly on heating (Balard, *C. R.* 19, 909; Rammelsberg, *P.* 42, 114; 90, 35; Clarke, *J.* 1877, 43). The following double cyanides have also been isolated:  $\text{NiCy}_2.2\text{NH}_4\text{Cy}$  (Wöhler, *Gehlen's Journ.* 6, 234);  $\text{NiCy}_2.\text{BaCy}_2.3\text{H}_2\text{O}$  (Wöhler, *l.c.*; Weselsky, *B.* 2, 588; Mouthiers, *A.* 64, 297);  $\text{NiCy}_2.\text{CaCy}_2.x\text{H}_2\text{O}$  (Wöhler, *l.c.*);  $\text{NiCy}_2.2\text{NaCy}.3\text{H}_2\text{O}$  (Wöhler, *l.c.*; Rammelsberg, *P.* 42, 114);  $\text{NiCy}_2.\text{SrCy}_2.x\text{H}_2\text{O}$  (Handl, *W. A. B.* 32, 246). Solutions of these double cyanides are decomposed by dilute acids with ppn. of  $\text{NiCy}_2$ , and evolution of  $\text{HCy}$ ;  $\text{HgO}$  decomposes them ppg.  $\text{NiCy}_2$  and  $\text{NiO}$ ; Cl or Br ppts.  $\text{Ni}_2\text{O}_3$ .

**Niobium cyanide.** No cyanide of Nb has been isolated. When  $\text{Nb}_2\text{O}_5$  is strongly heated with  $\text{Na}_2\text{CO}_3$  and charcoal in a current of air, a metallic solid is formed resembling the compound of Ti with Cy and N; this solid is possibly analogous in composition to the Ti compound (*v.* TITANIUM CYANIDES) (Joly, *C. R.* 82, 1195).

**Osmium cyanides.** One cyanide of Os,  $\text{OsCy}_2$ , and osmocyanyhydric acid  $\text{H.OsCy}_6$  and some of its salts, have been prepared.

**Osmous cyanide**  $\text{OsCy}_2$ . Dark violet solid obtained by continued boiling  $\text{H.OsCy}_6$  with  $\text{HClAq}$  (Martius, *A.* 117, 357).

**Osmocyanyhydric acid**  $\text{H.OsCy}_6$ . Obtained by adding conc.  $\text{HClAq}$  to  $\text{K.OsCy}_6\text{Aq}$  (*q. v.*), collecting the pp. which forms, washing it with conc.  $\text{HClAq}$ , and crystallising from alcohol by adding a few drops of ether. White hexagonal prisms; unchanged in dry air; in moist air decomposes to  $\text{OsCy}_2$  and  $\text{HCN}$ ; sol. in water and alcohol, ppd. by a little ether (Martius, *A.* 117, 357).

**Osmocyanides.**  $\text{K.OsCy}_2.3\text{H}_2\text{O}$ ; prepared

by dissolving 1 part osmic acid in  $\text{KOHaq}$  until the liquid remains feebly alkaline, adding 14 parts  $\text{KCy}$ , evaporating to dryness, heating in a closed vessel, dissolving in water, and crystallising once or twice (Martius, *A.* 117, 357; Claus, *Beiträge z. Chemie d. Platinmetalle* [Dorpat, 1854], or *J.* 1855, 444; Claus, *J. pr.* 85, 129). Yellow-white plates isomorphous with  $\text{K.FeCy}_2$  (Claus, *J. pr.* 85, 129). The following osmocyanides have also been described:  $\text{Ba.OsCy}_2.6\text{H}_2\text{O}$  (Martius, *A.* 117, 357);  $\text{BaK.OsCy}_2.3\text{H}_2\text{O}$  (Martius, *l.c.*).  $\text{K.OsCy}_6\text{Aq}$  gives pps. with many metallic salts.

**Palladium cyanides.** Two cyanides of Pd,  $\text{PdCy}_2$  and  $\text{PdCy}_4$ , are known. Several double cyanides of  $\text{PdCy}_2$  have been prepared. They may be regarded as derivatives of the hypothetical palladium-cyanhydric acid  $\text{H}_2\text{PdCy}_4$ ; this acid has not been isolated, but the analogies in crystalline form and general properties between the double cyanides of  $\text{PdCy}_2$  and those of  $\text{PtCy}_2$  point to the Pd salts as being derived from  $\text{H}_2\text{PdCy}_4$ ; the acid  $\text{H}_2\text{PtCy}_4$  is known.

**Palladous cyanide**  $\text{PdCy}_2$ . Yellow-white pp. obtained by adding  $\text{HgCy}_2\text{Aq}$  to neutral  $\text{PdCl}_2$  solution. Decomposed by heat to Pd and Cy; not decomposed by ordinary acids nor by  $\text{H}_2\text{O}$ ; soluble in  $\text{NH}_4\text{Aq}$ , from which solution the compound  $\text{PdCy}_2.2\text{NH}_3$  separates in white needles; soluble in  $\text{KCyaq}$  forming  $\text{PdCy}_2.2\text{KCy}$  (Berzelius, *P.* 13, 460; Fehling, *A.* 39, 119; Rössler, *Z.* 1866, 175). Joannis (*C. R.* 95, 295) gives some thermal data:  $[\text{PdCy}] = 23,600$  (solid  $\text{PdCy}_2$  from gaseous Cy and solid Pd);  $[\text{PdO}.2\text{HCyaq}] = 44,800$  (giving solid  $\text{PdCy}_2$ ).

**Palladic cyanide**  $\text{PdCy}_4$ . Reddish pp. easily decomposing with evolution of  $\text{HCN}$ ; obtained by shaking  $\text{HgCy}_2\text{Aq}$  with  $\text{PdCl}_2.2\text{KCl}$ .

Double cyanides of palladous cyanide, or pallado-cyanides.  $\text{PdCy}_2.2\text{NH}_4\text{Cy}$  (or  $(\text{NH}_4)_2\text{PdCy}_4$ ); obtained by adding  $\text{HgCy}_2\text{Aq}$  to an ammoniacal solution of a palladous salt; said to be ppd. by adding  $\text{HCNAq}$  to  $\text{PdCl}_2.2\text{NH}_4\text{Cl}$  (Croft, *J. pr.* 104, 64; *v.* also Rössler, *Z.* 1866, 175).  $\text{PdCy}_2.\text{BaCy}_2$  (or  $\text{BaPdCy}_4$ ).  $4\text{H}_2\text{O}$ ; large greenish monoclinic prisms; formed by adding  $\text{HCNAq}$  to a mixture of  $\text{PdCy}_2$  and  $\text{BaCO}_3$  (Rössler, *Z.* 1866, 175; Weselsky, *B.* 2, 588).  $\text{PdCy}_2.2\text{KCy}$  (or  $\text{K}_2\text{PdCy}_4$ ); obtained by dissolving  $\text{PdCy}_2$  or Pd black in  $\text{KCyaq}$ , and crystallising. Crystallises with  $3\text{H}_2\text{O}$  in white monoclinic crystals, or with  $\text{H}_2\text{O}$  in lustrous tablets (Rössler, *Z.* 1866, 175). The following double cyanides are also described by Rössler (*l.c.*):  $\text{PdCy}_2.\text{CaCy}_2.4\text{H}_2\text{O}$ ;  $\text{PdCy}_2.\text{CuCy}_2$ ;  $\text{PdCy}_2.\text{PbCy}_2$ ;  $\text{PdCy}_2.\text{MgCy}_2.4\text{H}_2\text{O}$ , this compound forms the complex cyanide  $\text{MgPdCy}_2.\text{MgPtCy}_2.14\text{H}_2\text{O}$  (Rössler);  $\text{PdCy}_2.\text{HgCy}_2$ ;  $\text{PdCy}_2.2\text{AgCy}_2$ ;  $\text{PdCy}_2.2\text{NaCy}_2$ . Most of these double cyanides are isomorphous with the corresponding platino-cyanides which are derivatives of the acid  $\text{H}_2\text{PtCy}_4$ . Solutions of the Pd double cyanides are decomposed, slowly in air, more quickly by acids, with separation of  $\text{PdCy}_2$ ;  $\text{H}_2\text{S}$  ppts.  $\text{PdS}$ ; Zn ppts. Pd.

**Platinum cyanide**  $\text{PtCy}_2$ . Platinum cyanide  $\text{PtCy}_2$  is known; also platincyanyhydric acid  $\text{H}_2\text{PtCy}_4$ , and many salts derived therefrom; there are also several compounds which may be regarded as additive compounds of the platino-cyanides with halogens, or better as derivatives of perchloro-(bromo- or iodo-) platincyanyhydric acid

$H_2X_2PtCy_2$ ; and finally there are some compounds of doubtful composition.

**Platinous cyanide**  $PtCy_2$ . Obtained by heating  $PtCy_2 \cdot 2KCy$  (prepared by heating  $KCy \cdot Aq$  with conc.  $PtCl_2 \cdot Aq$ , or by warming  $PtCl_2 \cdot 2NH_4Cl$  with  $KCy$  and a little  $KOH$ ) with  $HgCl_2$ ; or by heating  $PtCy_2 \cdot HgCy_2$  (prepared by adding  $HgCl_2 \cdot Aq$  to  $PtCy_2 \cdot 2KCy \cdot Aq$ ) (Döbereiner, *A.* 17, 250; Quadrat, *A.* 63, 164). Also formed by heating  $PtCy_2 \cdot 2NH_4Cy$  to  $300^\circ$  (Schafarik, *J. pr.* 66, 385); also by heating  $PtCy_2 \cdot 2KCy$  with conc.  $H_2SO_4$  (Knop a. Schnedermann, *J. pr.* 37, 461); also by ppg. neutral  $PtCl_2 \cdot Aq$  by  $HgCy_2 \cdot Aq$  (Rossler, *Z.* 1866, 175); also, along with other products, by heating  $H_2PtCy_2$  with  $HNO_3 \cdot Aq$  (Schafarik, *l.c.*). Sulphur-coloured solid; insol. in water, acids, and alkalis; when heated gives  $Cy$  and  $Pt$ ; dissolves in alkali cyanides forming platinocyanides; when freshly pptd dissolves in  $NH_4Aq$ .

**Platinocyanhydric acid**  $H_2PtCy_2$ .  $HCN$  is passed into a mixture of 1 part  $PtCl_2$  with  $1\frac{1}{2}$  parts  $BaCO_3$  suspended in 5 parts water kept nearly boiling; the passage of  $HCN$  is continued so long as  $CO_2$  is evolved;  $BaPtCy_2 \cdot 4H_2O$  crystallises out on cooling; this salt is dissolved in water (1 part dissolves in 33 parts water at  $16^\circ$ ), and an equivalent quantity of  $H_2SO_4 \cdot Aq$  is added; the filtrate from the ppt.  $BaSO_4$  is evaporated at a gentle heat and crystallised (Weselsky, *J. pr.* 69, 276). Or  $CuPtCy_2$  is prepared by adding  $PtCy_2 \cdot 2KCy \cdot Aq$  to  $Cu(NO_3)_2 \cdot Aq$ , and the  $Cu$  salt is decomposed by  $H_2S$  (Quadrat, *A.* 63, 164). Crystallises with  $5H_2O$  in cinnabar-red prisms with blue sheen on surface, or with more than  $5H_2O$  in yellow-green, metal-like crystals, or in blue-black needles. Deliquescent. Very sol. in water and alcohol. Heated, decomposes above  $140^\circ$  to  $HCN$  and  $PtCy_2$ . Carbonates are decomposed by  $H_2PtCy_2$ .

**Platinocyanides**. These salts generally form very beautiful dichroic crystals; the soluble salts may be prepared by decomposing  $BaPtCy_2$  by the various metallic sulphates; the insoluble platinocyanides may be formed by adding the various metallic salts to  $K_2PtCy_2 \cdot Aq$ .

**Ammonium platinocyanide**  $(NH_4)_2PtCy_2 \cdot H_2O$ . White, translucent needles; crystallises with  $2H_2O$  as yellow prisms; both with blue reflection. V. sol. water (Schafarik, *J. pr.* 66, 385; Quadrat, *A.* 63, 164; Knop a. Schnedermann, *J. pr.* 37, 461). An hydroxylammonium salt  $(NH_4O)_2PtCy_2 \cdot 2H_2O$  is known; and also the double salt  $(NH_4 \cdot NH_4O)PtCy_2 \cdot 3\frac{1}{2}H_2O$  (Scholz, *M.* 1, 900).

**Barium platinocyanide**  $BaPtCy_2 \cdot 4H_2O$ . Prepared by passing  $HCN$  into 5 parts almost boiling water holding 1 part  $PtCl_2$  and  $1\frac{1}{2}$  parts  $BaCO_3$  in suspension, until  $CO_2$  ceases to be evolved, and crystallising (Weselsky, *J. pr.* 69, 276);  $PtCl_2$  may be used in place of  $PtCl_4$  in which case  $O$  is evolved  $(PtCl_4 + 3BaCO_3 + 4HCN = BaPtCy_2 + 2BaCl_2 + 2H_2O + 3CO_2 + O)$ ; Weselsky, *J. pr.* 103, 566). Monoclinic prisms. S.G. 3.054 (Schabus, *W. A. B.* 1850, 582). Crystals appear green in direction of principal axis, and sulphur yellow with blue-violet sheen in direction at right angles to this. Soluble in 33 parts water at  $16^\circ$ , considerably more sol. at  $100^\circ$ . Loses all water at  $180^\circ$ , and begins to decompose. Forms double compounds,  $BaPtCy_2 \cdot K_2PtCy_2$ ,

(Martius, *A.* 117, 357), and  $BaPtCy_2 \cdot Rb_2PtCy_2$  (Ditscheiner, *W. A. B.* 50, 373).

**Magnesium platinocyanide**  $MgPtCy_2 \cdot 7H_2O$ . Prepared by adding  $MgSO_4 \cdot Aq$  to  $BaPtCy_2 \cdot Aq$ , filtering, evaporating to dryness, dissolving in a boiling mixture of alcohol and ether, and crystallising. Red quadratic prisms, showing greenish on the surfaces near the middle of the crystals and blue near the extremities (Haidinger, *P.* 77, 89; Werther, *J. pr.* 76, 186; Greiss, *P.* 106, 643). At  $40^\circ$  loses water, turning yellow. The yellow salt may be obtained in fine crystals by evaporating an alcoholic solution of the salts with  $7H_2O$  over  $H_2SO_4$ ; the crystals contain  $5H_2O$  (Werther, *J. pr.* 76, 186). Becomes colourless at c.  $100^\circ$ ; at  $150^\circ$  still contains  $2H_2O$ ; dehydrated at  $200^\circ$ – $230^\circ$ , becoming orange yellow (Werther, *l.c.*). (For more details v. Schafarik, *J. pr.* 66, 385; Quadrat, *A.* 63, 164; 70, 300; Weselsky, *J. pr.* 69, 276.)

**Mercuric platinocyanide**  $Hg_2PtCy_2$ . White pp. obtained by adding  $HgCl_2 \cdot Aq$  to  $K_2PtCy_2 \cdot Aq$  (Schafarik, *J. pr.* 66, 385).

**Platino-ammonium platinocyanide**  $PtPtCy_2 \cdot 4NH_3$ . (Platino-cyano-diplatino-ammonium. Ammonium-platinoammonium platinocyanide.) White pp. obtained by adding  $KCy \cdot Aq$  to ammoniacal  $PtCl_2$  solution. With  $AgNO_3 \cdot Aq$  forms  $Ag_2PtCy_2$  and  $Pt(NO_3)_2 \cdot 4NH_3$  (Knop a. Schnedermann, *J. pr.* 37, 461; Buckton, *A.* 78, 328).

**Potassium platinocyanide**  $K_2PtCy_2 \cdot 3H_2O$ . Clear yellow rhombic prisms, with blue appearance in direction of principal axis. S.G. 2.1548 at  $16^\circ$  (Clarke, *J.* 1877, 43). Effloresces in air, becoming nearly white with slight orange tint. Does not decompose at c.  $600^\circ$ . Sl. sol. cold, v. sol. hot, water. Decomposed by  $H_2SO_4 \cdot Aq$  in the cold, giving  $PtCy_2$  and  $CO_2$ . Solution gives white pp with mercurous salts with  $Hg$  not in excess, and a blue pp. with excess of  $Hg$  salts; this reaction characterises platinocyanides. The salt may be obtained by dissolving  $PtCl_2 \cdot 2NH_4Cl$  with a little  $KOH$  in a conc. boiling solution of  $KCy$ , and crystallising from water (Martius, *A.* 117, 357). It is also produced by boiling  $Pt$  black with conc.  $KCy \cdot Aq$  (Deville a. D. Bray, *C. R.* 82, 241); also by heating a mixture of  $Pt$  black and  $K_2FeCy_6$  nearly to redness, treating with water, filtering, evaporating, and recrystallising from water the crystals which separate.

**Silver platinocyanide**  $Ag_2PtCy_2$ . White pp. by adding  $AgNO_3 \cdot Aq$  to  $K_2PtCy_2 \cdot Aq$ . Combines with  $NH_3$  to form  $Ag_2PtCy_2 \cdot 2NH_3$  (Knop a. Schnedermann, *J. pr.* 37, 461); prepared by adding  $K_2PtCy_2 \cdot Aq$  to ammoniacal  $AgNO_3 \cdot Aq$ , or to a solution of  $Ag_2CO_3$  in  $(NH_4)_2CO_3 \cdot Aq$ . Sol. dilute  $NH_4Aq$ , not in water.

Besides the preceding platinocyanides, the following have been isolated:— $CaPtCy_2 \cdot 5H_2O$ ; and  $CaPtCy_2 \cdot K_2PtCy_2$  (Döbereiner, *A.* 17, 250; Martius, *A.* 117, 357; Quadrat, *A.* 70, 300),  $CdPtCy_2$ ,  $CdPtCy_2 \cdot 2NH_3 \cdot H_2O$ , and  $PbPtCy_2 \cdot xH_2O$  (Martius, *l.c.*).  $CuPtCy_2 \cdot xH_2O$ ;  $CuPtCy_2 \cdot 2NH_3 \cdot H_2O$ ;  $Na_2PtCy_2 \cdot 3H_2O$ ;  $NaK_2PtCy_2 \cdot 3H_2O$ ;  $SrPtCy_2 \cdot 5H_2O$  (Schafarik, *J. pr.* 66, 385; Quadrat, *A.* 63, 164; Martius, *l.c.*).  $Ce_2(PtCy_2)_3 \cdot 18H_2O$ ;  $La_2(PtCy_2)_3 \cdot 18H_2O$  (Czudnowicz, *J. pr.* 80, 16).  $CoPtCy_2 \cdot 2NH_3$ ;  $NiPtCy_2 \cdot 2NH_3 \cdot H_2O$ ;  $ZnPtCy_2 \cdot 2NH_3 \cdot H_2O$  (Knop

a. Schmedermann, *J. pr.* 37, 461).  
 $\text{Di}(\text{PtCy}_2)_2 \cdot 18\text{H}_2\text{O}$  (Clève, *Bl.* [2] 21, 246).  
 $\text{Er}_2(\text{PtCy}_2)_2 \cdot 21\text{H}_2\text{O}$ ;  $\text{Y}_2(\text{PtCy}_2)_2 \cdot 21\text{H}_2\text{O}$  (Clève a. Hoeglund, *Bl.* [2] 18, 197).  $\text{Li}_2\text{PtCy}_2 \cdot x\text{H}_2\text{O}$ ;  
 $\text{Li}(\text{NH}_4\text{O})\text{PtCy}_2 \cdot 3\text{H}_2\text{O}$  (Scholz, *M.* 1, 900).  
 $\text{ThPtCy}_2 \cdot x\text{H}_2\text{O}$  (Ditscheiner, *W. A. B.* 50, 373).  
 $\text{Ti}_2\text{PtCy}_2$ ;  $\text{TiPtCy}_2 \cdot \text{Ti}_2\text{CO}$  (Friswell, *A.* 159, 383;  
 F. a. Greenaway, *B.* 10, 1858).  $\text{Th}(\text{PtCy}_2)_2 \cdot 16\text{H}_2\text{O}$   
 (Clève, *Bl.* [2] 21, 116).

The salts  $(\text{NH}_4\text{Me})_2\text{PtCy}_2$ ,  $(\text{NH}_4\text{Et})_2\text{PtCy}_2$ ,  
 $(\text{NH}_4\text{Et}_2)_2\text{PtCy}_2$ , and  $(\text{NH}_4\text{Et}_3)_2\text{PtCy}_2$ , have been  
 isolated (Debus, *A.* 128, 200; Scholz, *M.* 1, 900).  
 $\text{Et}_2\text{PtCy}_2$  is described by Than (*A.* 107, 315);  
 also salts of aniline, paratoluidine, and  $\alpha$ -naph-  
 thylamine (Scholz, *loc.*). Salts of alkaloïds are  
 also known (v. Schwarzenbach, *Vierteljahr.*  
*Pharm.* 6, 422; Delfs, *Fr.* 3, 152).

Halogen addition products of pla-  
 tinocyanides, or salts of perchloro-,  
 perbromo-, and periodo-platinocyanhy-  
 dric acid. These salts have the general form

and  $\text{X} = \text{Cl}, \text{Br}, \text{or I}$ . They were first obtained  
 by Hadow (*C. J.* 13, 106), and have been  
 examined also by Blomstrand (*J. pr.* [2] 3, 207),  
 and by Holst (*Bl.* [2] 22, 347). Alkalis, or  
 $\text{AgNO}_3\text{Aq}$ , withdraw halogen from these salts  
 re-producing the platinocyanides. These salts  
 give white pps. with excess of  $\text{HgNO}_3\text{Aq}$ , whereas  
 platinocyanides give blue pps. under same con-  
 ditions. When conc. solutions of the perhaloid-  
 platinocyanides are mixed with conc. solutions of  
 platinocyanides, double compounds of the form  
 $5\text{M}_2\text{PtCy}_2 \cdot \text{M}_2\text{PtCy}_2 \cdot \text{X}_2$  are pptd. (v. CHLORO- &c.  
 PLATINOCYANIDES, *infra*). These salts bleach in  
 presence of alkalis; the chloro- and bromo- salts  
 decompose KI.

*Potassium perchloroplatinocyanide*  
 $\text{K}_2\text{PtCy}_2 \cdot \text{Cl}_2 \cdot 2\text{H}_2\text{O}$  (Knop a. Schmedermann, *J. pr.*  
 37, 461). This salt was formerly regarded as  
 $\text{PtCy}_2 \cdot 2\text{KCl}$ , i.e. as a double compound of KCl  
 with the hypothetical  $\text{PtCy}_2$ ; but the researches  
 of Hadow show that it is rather to be looked on  
 as the final product of the reaction of Cl with  
 $\text{K}_2\text{PtCy}_2$ , the intermediate product being the  
 salt (described below)  $5\text{K}_2\text{PtCy}_2 \cdot \text{K}_2\text{PtCy}_2 \cdot \text{Cl}_2$ , which  
 is called by Hadow *potassium-chloroplatinocyanide*.  
*Potassium perchloroplatinocyanide* is  
 prepared by dissolving K-chloroplatinocyanide  
 (q. v.) in nearly boiling *aqua regia* and crystal-  
 lising (K. a. S.), or by oxidising the same salt by  
 $\text{KMnO}_4$  in presence of HCl, evaporating at  $100^\circ$ ,  
 and crystallising. Large rhomboidal triclinic  
 plates; v. sol. water and alcohol; very efflu-  
 escent; heated gives off  $\text{Cy}$ , leaving KCl and  
 $\text{K}_2\text{PtCy}_2$ , and at a higher temperature gives KCl  
 and Pt. Partially reduced by Zn and  $\text{NH}_4\text{Aq}$ , or  
 by  $\text{SO}_3\text{Aq}$ , to mixture of  $\text{K}_2\text{PtCy}_2$  and  $6\text{K}_2\text{PtCy}_2 \cdot \text{Cl}_2$   
 (K-chloroplatinocyanide). When conc. solution  
 of  $\text{K}_2\text{PtCy}_2 \cdot \text{Cl}_2$  and  $\text{K}_2\text{PtCy}_2$  are mixed crystals of  
 the chloroplatinocyanide ( $5\text{K}_2\text{PtCy}_2 \cdot \text{K}_2\text{PtCy}_2 \cdot \text{Cl}_2$ )  
 are deposited.

The following perchloroplatinocyan-  
 ides have been isolated, besides the K salt:—  
 $(\text{NH}_4)_2\text{X} \cdot 2\text{H}_2\text{O}$ ;  $\text{BaX} \cdot 5\text{H}_2\text{O}$ ;  $\text{CaX}$ ;  $\text{MgX} \cdot x\text{H}_2\text{O}$ ;  
 $\text{MnX} \cdot 2\text{H}_2\text{O}$  (Holst, *Bl.* [2] 22, 347) [ $\text{X} = \text{PtCy}_2 \cdot \text{Cl}_2$ ].

*Perchloro-platinocyanhydric acid*  
 $\text{H}_2\text{PtCy}_2 \cdot \text{Cl}_2 \cdot 4\text{H}_2\text{O}$  (Holst, *loc.*). Obtained by de-  
 composing the Ba salt (itself produced by passing

Cl into  $\text{BaPtCy}_2\text{Aq}$  by  $\text{H}_2\text{SO}_4\text{Aq}$ , filtering and  
 crystallising. White crystals; very soluble in  
 water and alcohol.

*Perbromo-platinocyanhydric acid*  
 $\text{H}_2\text{PtCy}_2 \cdot \text{Br}_2 \cdot x\text{H}_2\text{O}$  (Holst, *loc.*) is obtained by  
 adding Br to  $\text{BaPtCy}_2\text{Aq}$  and crystallising; it  
 forms white crystals very sol. in alcohol and  
 ether.

Several perbromo-platinocyanides and  
 some periodoplatinocyanides have been  
 isolated; they are produced by the action of I or  
 I on the platinocyanides; the salts of the  
 alkalis and alkaline earths are very soluble in  
 water and may generally be easily crystallised;  
 most of the salts of the heavy metals are insol.  
 or only sl. sol. in water. Holst (*loc.*) describes  
 the following:— $[\text{X} = \text{PtCy}_2 \cdot \text{Br}_2]$   $\text{Al}_2 \cdot x \cdot 22\text{H}_2\text{O}$ ;  
 $(\text{NH}_4)_2\text{X}$ ;  $\text{BaX} \cdot 5\text{H}_2\text{O}$ ;  $\text{BeX}$ ;  $\text{CdX} \cdot x\text{H}_2\text{O}$ ;  
 $\text{CoX} \cdot 5\text{H}_2\text{O}$ ;  $\text{PbX} \cdot 2\text{H}_2\text{O}$ ;  $\text{Li}_2\text{X}$ ;  $\text{MgX} \cdot x\text{H}_2\text{O}$ ;  
 $\text{NiX} \cdot x\text{H}_2\text{O}$ ;  $\text{R}_2\text{X}$ ;  $\text{Na}_2\text{X}$ ;  $\text{SrX} \cdot 7\text{H}_2\text{O}$ ;  $\text{ZnX} \cdot 5\text{H}_2\text{O}$ .  
 The periodo- salts described by Holst are  
 $\text{BaPtCy}_2 \cdot \text{I}_2 \cdot x\text{H}_2\text{O}$ , and  $\text{K}_2\text{PtCy}_2 \cdot \text{I}_2$ .

Double compounds of platinocyan-  
 ides with perhaloid platinocyanides;  
 or chloro- &c. platinocyanides, or chloro-  
 &c. platinidplatinocyanides. These salts  
 were formerly supposed to be double compounds  
 of KCl &c. with the hypothetical  $\text{PtCy}_2$ , of the  
 form  $\text{M}_2\text{PtCy}_2 \cdot \text{PtCy}_2 \cdot 2\text{M}_2\text{Cy}_2$ . They are pro-  
 duced by the reaction of Cl, Br,  $\text{IINO}_3$ , and other  
 oxidisers, with the platinocyanides  $\text{M}_2\text{PtCy}_2$ .  
 The change was supposed to be somewhat analogous  
 to that which occurs when a ferrocyanide  
 $(\text{M}_2\text{FeCy}_6)$  is oxidised to a ferricyanide ( $\text{M}_2\text{FeCy}_6$ );  
 thus  $2\text{K}_2\text{FeCy}_6 + \text{O} = 2\text{K}_2\text{FeCy}_6 + \text{K}_2\text{O}$ , and  
 $3\text{K}_2\text{PtCy}_2 + \text{O} = 2\text{K}_2\text{PtCy}_2 + \text{PtCy}_2 + \text{K}_2\text{O}$ . In ac-  
 cordance with this conception, the compounds  
 were called *platiniccyanides* (and sometimes  
*platinosquacyanides* when their composition  
 was indicated by the formula  $\text{PtCy}_2 \cdot 4\text{M}_2\text{Cy}_2$ ).  
 Hadow (*C. J.* 13, 106), however, showed that  
 the salt of this series obtained by the limited  
 action of Cl on  $\text{K}_2\text{PtCy}_2$  contained Cl; his  
 analyses and methods of synthesis of the salt  
 led him to give it the formula  $(\text{K}_2\text{PtCy}_2)_2 \cdot \text{Cl}_2$ ,  
 and to indicate its formation by the reaction  
 $6\text{K}_2\text{PtCy}_2 + \text{Cl}_2 = 6(\text{K}_2\text{PtCy}_2)_2 \cdot \text{Cl}_2$ . The synthesis  
 of the same salt by mixing conc. solution of K  
 perchloroplatinocyanide ( $\text{K}_2\text{PtCy}_2 \cdot \text{Cl}_2$ ) and K  
 platinocyanide ( $\text{K}_2\text{PtCy}_2$ ) shows that the for-  
 mula  $6(\text{K}_2\text{PtCy}_2)_2 \cdot \text{Cl}_2$  is better written so as to  
 indicate that the salt is a double compound,  
 viz.  $5\text{K}_2\text{PtCy}_2 \cdot \text{K}_2\text{PtCy}_2 \cdot \text{Cl}_2$ ; this formula is con-  
 firmed by the fact that reducing agents (e.g.  
 $\text{SO}_3\text{Aq}$ , or Zn and  $\text{NH}_4\text{Aq}$ ) decompose the salt  
 to a mixture of  $\text{K}_2\text{PtCy}_2 \cdot \text{Cl}_2$  and  $\text{K}_2\text{PtCy}_2$ ; more-  
 over, the salt in question reacts with excess of  
 Cl to form  $\text{K}_2\text{PtCy}_2 \cdot \text{Cl}_2$ , and with excess of I or  
 Br to form  $\text{K}_2\text{PtCy}_2 \cdot \text{I}_2$  or  $\text{K}_2\text{PtCy}_2 \cdot \text{Br}_2$ , respec-  
 tively. Holst (*Bl.* 3, 121) got results which show  
 that although the composition of the chloro- &c.  
 platinocyanides is always to be represented by  
 the formula  $x\text{M}_2\text{PtCy}_2 \cdot y\text{M}_2\text{PtCy}_2 \cdot \text{X}_2$ , yet the ratio  
 of  $x:y$  is not always 5:1.

*Potassium chloroplatinocyanide*, or  
*Potassium chloroplatinidplatinocyanide*,  
 $5\text{K}_2\text{PtCy}_2 \cdot \text{K}_2\text{PtCy}_2 \cdot \text{Cl}_2 \cdot 21\text{H}_2\text{O}$  (Hadow, *C. J.*  
 13, 106; Knop, *A.* 43, 111). Cl is passed into  
 warm  $\text{K}_2\text{PtCy}_2\text{Aq}$  so conc. that crystals are de-  
 posited on cooling; the crystals are dried between  
 paper and recrystallised from water acidulated

with  $\text{HCl}$  (Knop). Hadow divides a solution of  $\text{K}_2\text{PtCy}_4$  into 6 parts; into  $\frac{1}{2}$  he passes  $\text{Cl}$  until the liquid is saturated ( $\text{K}_2\text{PtCy}_4\text{Cl}_2$  is thus formed), he then adds the remaining  $\frac{1}{2}$  and evaporates. Green prismatic crystals, with red metal-like surface colour by reflected light. Sol. in water giving colourless solution, insol. in alcohol. Gives off part of  $\text{H}_2\text{O}$  over  $\text{H}_2\text{SO}_4$ , becoming black; loses  $18\text{H}_2\text{O}$  at  $100^\circ$  and the rest at  $c. 180^\circ$ ; when strongly heated gives off  $\text{Cy}$ .

Holst (*B. 8, 124*) obtained the salt  $10\text{SrPtCy}_4 \cdot \text{SrPtCy}_4 \cdot 12\text{H}_2\text{O}$ .

Weselsky (*J. pr. 69, 276*) describes some salts obtained by the action of  $\text{HNO}_3\text{Aq}$  on platinumocyanides; he regards these as platinumocyanides or platinum sesquicyanides ( $\text{PtCy}_4 \cdot 4\text{M}^+\text{Cv}$ ); but it is very probable that they are analogous to Hadow's double compounds of platinumocyanides with perchloro- &c. platinumocyanides, only that the halogen is replaced either by  $\text{NO}$ , or  $\text{NO}_2$  (*cf.* Hadow, *C. J. 13, 106*; also *v. Martins, A. 117, 357*, for reaction of  $\text{PbPtCy}_4$  with  $\text{HNO}_3$ , whereby  $\alpha\text{PbPtCy}_4 \cdot y\text{PbPtCy}_4(\text{NO}_2)$  seems to be produced).

The compound obtained by Hadow by the action of  $\text{PbO}$  on  $\text{K}_2\text{PtCy}_4$  in  $\text{H}_2\text{SO}_4$  solution seems also to belong to this class and to have the halogen atoms replaced by the radicle  $\text{SO}_4$ .

**Potassium cyanide**  $\text{KCy}$ . *S.G.*  $1.52$  (Bödeker).  $[\text{K}, \text{CN}] = 65,350$ ;  $[\text{K}, \text{N}, \text{C}] = 32,500$ ;  $[\text{KCy}, \text{Aq}] = -3,010$  (*Th. 3, 235*);  $[\text{KOHAq}, \text{HCNAq}] = 2,770$  (*Th. 1, 160*).

*Occurrence.*—In blast furnaces.

*Formation.*—1. By fusing  $\text{K}$  in  $\text{Cy}$  or in  $\text{HCN}$  gas.—2. By fusing  $\text{K}_2\text{CO}_3$  with nitrogenous carbon.—3. By passing  $\text{N}$  over a strongly heated mixture of  $\text{C}$  and  $\text{KOH}$  or  $\text{K}_2\text{CO}_3$ .—4. By deflagrating  $\text{KNO}_3$  with  $\text{K}$  acetate, tartrate, &c., especially by heating a mixture of  $\text{KNO}_3$ ,  $\text{K}_2\text{CO}_3$ , and  $\text{KCH}_3\text{O}_2$  (Desfosses, *A. Ch. 38, 158*; Fownes, *J. pr. 26, 412*; Delbuck, *A. 64, 296*; Bunsen & Playfair, *J. pr. 42, 397*; Reiken, *A. 79, 77*; Langlois, *A. Ch. [3] 62, 326*; Roussin, *C. R. 47, 875*).—5. By passing  $\text{NH}_3$  over a heated mixture of  $\text{C}$  and  $\text{K}_2\text{CO}_3$  or  $\text{KOH}$  (Kuhlmann, *A. 38, 62*).

*Preparation.*—1. Ordinary commercial KCN (containing  $\text{KCN}$ ) is prepared by fusing dry  $\text{K}_2\text{FeCy}_6$  with  $\text{K}_2\text{CO}_3$  [ $2\text{K}_2\text{FeCy}_6 + 2\text{K}_2\text{CO}_3 = 10\text{KCN} + 2\text{KCNO} + 2\text{Fe} + 2\text{CO}_2$ ]; the fused mass is poured off from the iron.—2.  $\text{HCN}$  gas is passed into alcoholic solution of  $\text{KOH}$  (1 part  $\text{KOH}$  in 3 parts alcohol) (Wiggers, *A. 29, 65*). An aqueous solution of pure  $\text{KCN}$  is obtained by passing  $\text{HCN}$  into  $\text{KOHAq}$ .—3. Nearly pure  $\text{KCN}$  is prepared by fusing dry  $\text{K}_2\text{FeCy}_6$  in absence of air, and treating with 50 p.c. hot alcohol (Geiger, *A. 1, 46*);  $[2\text{K}_2\text{FeCy}_6 = 8\text{KCN} + 2\text{FeC}_2 + 2\text{N}_2]$ .

*Properties.*—Crystallises from alcohol, or by slowly cooling the fused salts, in white cubes, or octahedra, *v. sol.* in water; deliquescent; *sl. sol.* in strong alcohol. *Very poisonous*. Melts easily, and volatiles unchanged (in absence of moisture) at full red heat.

*Reactions.*—1. *Aqueous solution* decomposes in air, slowly at ordinary temperature, rapidly at  $100^\circ$ , giving  $\text{HCO}_2\text{K}$  and  $\text{NH}_3$ .—2. *Melted in air* forms  $\text{KCNO}$ .—3. Heated with *metallic nitrates* gives  $\text{KCNO}$  and metal; thus acts as an *energetic reducer*, *eg.* reduces oxides of  $\text{Pb}$ ,  $\text{Fe}$ ,

$\text{Sb}$ ,  $\text{Sn}$ , &c. &c., when heated with them.—4. Heated with *potassium chlorate* or *nitrate*, detonates violently.—5. Reduces *alkaline sulphates* to sulphides by heating with them.—6. With *solution of potassium permanganate*,  $\text{KCN}$  forms  $\text{CO}$ ,  $\text{HNO}$ ,  $\text{HNO}_2$ ,  $\text{H}_2\text{C}_2\text{O}_4$ ,  $\text{H}_2\text{CO}_3$ , and  $\text{CO}_2\text{NH}_2$  (Schlagdenhauffen, *J. 1863, 305*).—7. With *alkali polysulphides*,  $\text{KCN}$  forms  $\text{KCNSAq}$ .—8. With *iodine* in conc. solution  $\text{KCN}$  forms  $\text{KI}$  and  $\text{CyI}$ .—9. With *sodium thio-sulphate* forms  $\text{NaCNS}$ .—10. With *potash* produces  $\text{NH}_3$  and  $\text{HCO}_2\text{K}$ ; heated to redness with  $\text{KOH}$ ,  $\text{K}_2\text{CO}_3$  is formed and  $\text{H}$  evolved.

*Combination.*—1.  $\text{KCN}$  dissolves many *metallic cyanides* forming double cyanides, *eg.*  $\text{HgCy}_2$ ,  $\text{AuCy}$ ,  $\text{PtCy}_2$ ,  $\text{Cu}_2\text{Cy}_2$ , &c. (*v. various metallic cyanides*).—2. When *sulphur dioxide* is passed into cold conc.  $\text{KCN}$ , two compounds are formed,  $\text{CNK} \cdot \text{SO}_2 \cdot \text{H}_2\text{O}$  and  $\text{CNK} \cdot \text{SO}_2 \cdot \text{KH}_2\text{SO}_4$ ; they may be crystallised (Etard, *C. R. 88, 649*).

*Testing KCN for common impurities.*—The chief impurities in ordinary  $\text{KCN}$  are  $\text{KCNO}$ ,  $\text{K}_2\text{CO}_3$ ,  $\text{K}_2\text{S}$ ,  $\text{KCNS}$ ,  $\text{KHCO}_2$ ,  $\text{K}_2\text{FeCy}_6$ ,  $\text{K}_2\text{SO}_4$ , and  $\text{KCl}$ .  $\text{K}_2\text{CO}_3$  is detected by treating with alcohol at  $80^\circ$  and examining the insoluble portion by the ordinary tests.  $\text{K}_2\text{S}$ ;  $\text{Pb}$  salts give a black pp., in absence of  $\text{K}_2\text{S}$  a white pp. is formed.  $\text{KCNS}$ ;  $\text{HClAq}$  is added and the  $\text{HCN}$  is removed by warming; a few drops of  $\text{FeCl}_3\text{Aq}$  are added, when a deep-red colour shows  $\text{KCNO}$ .  $\text{KCNO}$ ; alcohol at  $80^\circ$  is added and the solution is acidulated, effervescence shows  $\text{KCNO}$ .  $\text{KHCO}_2$ ; a current of  $\text{CO}$  is passed through until  $\text{HCN}$  is removed, the liquid is evaporated to dryness, the residue is distilled with  $\text{H}_2\text{SO}_4\text{Aq}$ , and to the distillate are applied the ordinary tests for formic acid.  $\text{K}_2\text{FeCy}_6$ ; pure  $\text{FeCl}_3\text{Aq}$  gives blue pp. or blue colouration.  $\text{K}_2\text{SO}_4$ ;  $\text{HCN}$  is removed by warming with  $\text{HClAq}$  and  $\text{Ba}_2\text{NO}_3\text{Aq}$  is added.  $\text{KCl}$ ; the specimen is heated with 2 parts  $\text{KNO}_3$  and 10 parts  $\text{Na}_2\text{CO}_3$ , the fused mass is heated with water, and  $\text{AgNO}_3$  and  $\text{HNO}_3\text{Aq}$  added to the aqueous solution to pp.  $\text{AgCl}$ .

**Rhodium cyanides.**  $\text{Rh}_2\text{Cy}_6$ , and a rhodicyanide  $\text{K}_3\text{RhCy}_6$ , are known.

**Rhodium sesquicyanide**  $\text{Rh}_2\text{Cy}_6$ . Carmine-red powder, obtained by adding hot conc. acetic acid to  $\text{K}_3\text{RhCy}_6$  (Martius, *A. 117, 357*). Dissolves in  $\text{KCN}$  with re-formation of  $\text{K}_3\text{RhCy}_6$ .

**Potassium rhodicyanide**  $\text{K}_3\text{RhCy}_6$ . Monoclinic crystals: easily decomposed by acids; formed by fusing  $\text{RhCl}_3 \cdot 2\text{NH}_4\text{Cl}$  with  $\text{KCN}$  (Claus, *J. 1855, 441*).

**Ruthenium cyanides.** No simple cyanide has been isolated;  $\text{H}_2\text{RuCy}_6$ , and some of its salts are known.

**Rutheno-cyanhydric acid**  $\text{H}_2\text{RuCy}_6$  (Claus, *J. 1855, 441*). Obtained by adding  $\text{HClAq}$  and ether to the  $\text{K}$  salt (*q. v.*); lustrous, iridescent tablets; *e. sol.* alcohol and water; heated with  $\text{HClAq}$ ,  $\text{HCN}$  is evolved.

**Potassium rutheno-cyanide**  $\text{K}_3\text{RuCy}_6 \cdot 3\text{H}_2\text{O}$  (Claus, *l.c.*). Obtained by heating  $\text{KCN}$  with  $\text{RuCl}_3 \cdot 2\text{NH}_4\text{Cl}$ ; small, white, quadratic tablets, isomorphous with  $\text{K}_3\text{FeCy}_6$ . The solution of this salt gives coloured pps. with salts of  $\text{Cu}$ ,  $\text{Fe}$ ,  $\text{Pb}$ , and  $\text{Zn}$ .

**Silver cyanide**  $\text{AgCy}$ . Only one cyanide of  $\text{Ag}$  is known; it forms various double salts.

White, curdy pp. obtained by adding HCN<sub>aq</sub> or KCN<sub>aq</sub> to solution of a salt of Ag; excess of KCN must be avoided, as AgCy is sol. KCN<sub>aq</sub>; the pp. is dried at a temperature under 126°. S.G. c. 3.95 (Schröder, *B.* 13, 1074). H.F. [Ag, Cy] = 1,395; [Ag, C, N] = -81.455; [2HCyAg, Ag<sup>2</sup>O] = 42,310 (ppd. Ag<sub>2</sub>O; formation of solid AgCy) (*Th.* 3, 382). Not blackened by exposure to light. Sol. NH<sub>3</sub>Ag; sl. sol. boiling HNO<sub>3</sub>Ag; sol. KCN<sub>aq</sub>.

**Reactions.**—1. Heated, is decomposed to Ag and Cy.—2. Water at 280° forms NH<sub>3</sub>AgCO<sub>3</sub> (Reynoso, *A. Ch.* [3] 45, 111).—3. Chlorine forms AgCl and CyCl.—4. Sulphur heated with AgCy forms AgNCS.—5. Ammonia dissolves AgCN, forming AgCN.NH<sub>3</sub>.—6. Potassium cyanide dissolves AgCy, forming AgCy.KCy.—7. Decomposed by sulphuric acid or hydrochloric acid, with evolution of HCN.—8. Decomposed by sulphuretted hydrogen, also by sulphur chloride (Schneider, *J.* pr. 104, 83).

**Combinations.**—1. With ammonia to form AgCy.NH<sub>3</sub>; monoclinic tablets, which give off NH<sub>3</sub> in the air; obtained by heating AgCy in NH<sub>3</sub> (Weith, *Z.* 1869. 380; Liebig a. Redtenbacher, *A.* 33, 129).—2. With silver nitrate to form AgCy.AgNO<sub>3</sub> (or ?2AgCy.AgNO<sub>3</sub>) (Bloxam, *C. N.* 48, 154; Wohler, *P.* 1, 231); obtained by dissolving AgCy in hot conc. AgNO<sub>3</sub>Ag.

**Double cyanides containing silver cyanide.** The alkali salts are obtained by dissolving AgCy in solution of the alkali cyanide and evaporating; the salts of the heavy metals are generally obtained by adding AgCy.KCyAg to solutions of these metals.

**Silver-potassium cyanide** AgCy.KCy. Regular octahedra; sol. 4 parts water at 20°, and in 25 parts alcohol (85 p.c.). Decomposed by acids with separation of Ag<sub>2</sub>Cy. H<sub>2</sub>S ppts. Ag<sub>2</sub>S, except from solutions in much KCN<sub>aq</sub> (Glassford a. Napier, *P. M.* 15, 66; Rammelsberg, *P.* 38, 376; Baup, *A. Ch.* [3] 53, 462; Böchamp, *J.* pr. 60, 64). H.F. [Ag Cy; 2KCyAg] = 12,980; [Ag<sub>2</sub>Cy; 2KCyAg] = 15,780 (*Th.* 3, 470). The other important silver double cyanides are:—AgCy.NaCy; 3AgCy.2KCy.NaCy (Baup, *l.c.*); AgCy.TiCy (Fronmüller, *B.* 11, 91); AgCy.NMe<sub>3</sub>Cy (Thompson, *B.* 16, 2338; Claus a. Merck, *B.* 16, 2737); 2AgCy.HgCy<sub>2</sub>.HgSO<sub>4</sub>.H<sub>2</sub>O (Geuther, *A.* 106, 241).

**Sodium cyanide** NaCy. Prepared by passing HCN gas into an alcoholic solution of NaOH until NaCy pps. Obtained also by methods similar to those whereby KCy is formed (*v.* Potassium cyanide, p. 346). NaCy crystallises with difficulty. According to Joannis (*A. Ch.* [5] 27, 482) two hydrates are obtained by crystallising from alcohol at different temperatures; 2NaCy.H<sub>2</sub>O, and NaCy.2H<sub>2</sub>O. Joannis (*l.c.*) gives some thermal data:—[Na, Cy] = 60,400 (solid NaCy formed); [NaCy, Aq] = -500; [HCyAg, NaOH<sub>aq</sub>] = 2,900.

**Strontium cyanide** SrCy<sub>2</sub>. Prepared, similarly to BaCy<sub>2</sub>, by heating SrFeCy<sub>6</sub>; or preferably by passing HCN vapour into crystals of SrO<sub>2</sub>H<sub>2</sub>. Unstable salt. Crystallises from solution with 4H<sub>2</sub>O; the crystals are v. deliquescent and absorb CO<sub>2</sub> from the air (Joannis, *A. Ch.* [5] 27, 482; Schulz, *J.* pr. 68, 257). Joannis (*l.c.*) gives the thermal data:—[SrOAg, 2HCyAg] = 6,260.

**Thallium cyanides.** Two cyanides of Tl are known, TlCy and TlCy.TlCy<sub>2</sub>.

**Thallous cyanide** TlCy. Obtained by adding excess of conc. HCN<sub>aq</sub> to a conc. solution of a thallous salt, and then adding much alcohol and ether. Heavy white pp., s. sol. water, crystallising in lustrous tablets from the hot solution. Decomposed by heating (Fronmüller, *B.* 6, 1178).

**Thallo-thallic cyanide** TlCy.TlCy<sub>2</sub> (=Tl<sub>3</sub>Cy<sub>3</sub>). Formed by evaporating *in vacuo* a solution of Tl<sub>2</sub>O<sub>3</sub> in HCN<sub>aq</sub>. Large, white, rhombic plates; s. sol. water; decomposed at 125°-130° with rapid evolution of Cy (Fronmüller, *B.* 11, 91).

**Double cyanides containing thallous cyanide.**—TlCyAg dissolves the cyanides of Hg, Ag, and Zn; when the solutions are crystallised the following salts are obtained:—2TlCy.HgCy<sub>2</sub>; TlCy.AgCy<sub>2</sub>; 2TlCy.ZnCy<sub>2</sub> (Fronmüller, *B.* 11, 91). No double cyanides of Tl<sub>3</sub>Cy<sub>3</sub> are known.

**Titanium cyanides.** No cyanide of Ti is known, but the compound Ti<sub>3</sub>CN<sub>3</sub> exists; this body is almost certainly a double compound of Ti cyanide with Ti nitride TlCy<sub>2</sub>.3Ti<sub>3</sub>N<sub>2</sub>.

**Titanium cyano-nitride** TiCy<sub>2</sub>.3Ti<sub>3</sub>N<sub>2</sub>. This compound is formed in smelting titaniferous iron-stones in the blast furnace (Wöhler, *A.* 73, 34; 74, 212). It may be obtained by very strongly heating K<sub>2</sub>FeCy<sub>6</sub> with TiO<sub>2</sub> (Wöhler, *l.c.*), by heating KCN in vapour of TiCl<sub>4</sub>, and by passing N over a mixture of C and TiO, heated to the M.P. of Pt (Wöhler a. Deville, *A.* 103, 230). Metal-like, reddish octahedra, resembling metallic Cu. S.G. 5.28. Volatile at very high temperature. Not acted on by boiling HNO<sub>3</sub>Ag or H<sub>2</sub>SO<sub>4</sub>. Sol. HNO<sub>3</sub>Ag containing HF. Heated in water-gas is decomposed thus: Ti<sub>3</sub>CN<sub>3</sub> + 10H<sub>2</sub>O = CNH + 5TiO<sub>2</sub> + 3NH<sub>3</sub> + 5H<sub>2</sub>. Decomposed when heated with Cl<sub>2</sub>, giving TiCl<sub>4</sub>, and probably a compound of TiCl<sub>4</sub> with CyCl. Heated with KOH<sub>aq</sub> forms K titanate and NH<sub>3</sub>. CuO, PbO, and HgO are reduced to metals when heated with Ti<sub>3</sub>CN<sub>3</sub>.

**Uranium cyanide.** None has been certainly isolated. The oxides of U do not dissolve in HCN<sub>aq</sub>; addition of KCN<sub>aq</sub> to solution of U chloride ppts. an oxide of U (Rammelsberg, *P.* 59, 2). According to Wittstein (*R. P.* 63, 214), when KCN<sub>aq</sub> is added to a uranic salt solution a yellow pp. is obtained, sol. in excess of KCN<sub>aq</sub>, not ppd. again by acids.

**Vanadium cyanide.** None has been isolated. Berzelius made some observations on the reactions between vanadic acid and HCN (*P.* 22, 26).

**Yttrium cyanide.** No cyanide has been certainly isolated. Hydrated Y<sub>2</sub>O<sub>3</sub> is said to dissolve in HCN<sub>aq</sub>, and white nodules to be formed on evaporation (Berlin).

**Zinc cyanides.** ZnCy<sub>2</sub> is known, and also several double cyanides.

**Zinc cyanide** ZnCy<sub>2</sub>. Obtained by adding KCN<sub>aq</sub> (free from K<sub>2</sub>CO<sub>3</sub>) to solution of a Zn salt, or by adding HCN<sub>aq</sub> to Zn acetate solution. Special precautions are needed to insure production of pure ZnCy<sub>2</sub> (*v.* Wöhler, *B.* 7, 20, 152; Oppermann, *J.* 1860. 226; Joannis, *C. R.* 92, 1338, 1417; Rammelsberg, *P.* 42, 114). ZnCy<sub>2</sub> is obtained in crystals by covering a layer of conc. Zn(C<sub>2</sub>H<sub>3</sub>O<sub>2</sub>)<sub>2</sub>Ag with a little water, and

very carefully pouring on to this dilute  $\text{HCNAq}$ ; the crystals form slowly. Crystallises in orthorhombic prisms. The pp. by  $\text{KCN}$  and  $\text{HCN}$  is white with a tinge of yellow. Decomposed by strongly heating, giving off  $\text{Cy}$  (Rammelsberg). Insol. water and alcohol; e. sol. alkalis and  $\text{KCNaq}$ ; sl. sol. in conc. solutions of  $\text{Zn}$  salts (Joannis). With hot  $\text{KOHaq}$  it forms  $\text{K.O.ZnO}$  and  $\text{ZnCy}_2 \cdot 2\text{KCy}$ . H.F.  $[\text{ZnCy}] = 58,600$ ;  $[\text{ZnO}, 2\text{HCyAq}] = 13,400$  (Joannis).

Double cyanides containing  $\text{ZnCy}_2$ .—These compounds are obtained by dissolving  $\text{ZnCy}_2$  in a solution of the other cyanide and crystallising:—

$\text{ZnCy}_2 \cdot 2\text{NH}_4\text{Cy}$  (Corriol a. Berthemot, *J. Ph.* 16, 444).

$\text{ZnCy}_2 \cdot \text{BaCy}_2 \cdot 2\text{H}_2\text{O}$  (Weselsky, *B.* 2, 588).

$\text{ZnCy}_2 \cdot \text{CaCy}_2 \cdot x\text{H}_2\text{O}$  (Schindler, *Magaz. Pharm.* 86, 70).

$\text{ZnCy}_2 \cdot 2\text{KCy}$  (Gmelin; Fresenius a. Haidlen, *A.* 43, 132).  $[\text{ZnCy}, 2\text{KCyAq}] = 62,230$  (*Th.* 3, 475).

$\text{ZnCy}_2 \cdot 2\text{NaCy} \cdot 5\text{H}_2\text{O}$  (Rammelsberg, *P.* 42, 112).  $\text{ZnCy}_2 \cdot \text{HgCy}_2 \cdot \text{HgCl}_2 \cdot 6\text{H}_2\text{O}$  (Varet, *C. R.* 106, 1080).

$\text{ZnCy}_2 \cdot \text{HgCy}_2 \cdot \text{HgCl}_2 \cdot 6\text{NH}_4$  (Varet, *l.c.*).

**SELENOCYANIDES.** *Salts of selenocyanhydric acid  $\text{HSeCy}$ .* Also called *selenocyanates*. Discovered by Berzelius in 1820 (*S.* 31, 60); more fully examined by Crookes (*C. J.* 4, 12).

**Selenocyanhydric acid  $\text{HSeCyAq}$ .** (*Seleno-*, or *selenio-cyanic acid*. *Hydrogen seleno- or seleno-cyanate*. *Hydro-selenocyanic acid*.) Known only in solution; prepared by passing a rapid stream of  $\text{H}_2\text{S}$  through hot  $\text{Pb}(\text{SeCy})_2 \cdot \text{Aq}$  containing  $\text{Pb}(\text{SeCy})_2$  in suspension, filtering from  $\text{PbS}$ , heating the filtrate nearly to boiling, and filtering again (if necessary) from ppd.  $\text{Se}$ . This solution, which is markedly acid, is decomposed on boiling; it cannot be concentrated without change even over  $\text{H}_2\text{SO}_4$  *in vacuo*. It is decomposed by acids into  $\text{HCy}$  and  $\text{Se}$ . The solution dissolves  $\text{Zn}$  and  $\text{Fe}$  with evolution of  $\text{H}$  (Crookes, *C. J.* 4, 12).

**Ammonium selenocyanide  $\text{NH}_4\text{SeCy}$ .** By neutralising  $\text{HSeCyAq}$  by  $\text{NH}_4\text{Aq}$  and evaporating. Soluble, deliquescent, crystallises in minute needles (Crookes, *l.c.*).

**Barium, Calcium, and Strontium selenocyanides  $\text{M}(\text{SeCy})_2$**  [ $\text{M} = \text{Ba}, \text{Ca}, \text{or Sr}$ ]. By dissolving  $\text{MCO}$  in  $\text{HSeCyAq}$  and concentrating *in vacuo* (Crookes).

**Copper selenocyanide.** Brown pp. by adding  $\text{KSeCyAq}$  to  $\text{CuSO}_4\text{Aq}$ ; very soon decomposes to  $\text{HSeCyAq}$  and  $\text{CuSe}$  (*C.*).

**Gold selenocyanide.** Not isolated. When an alcoholic solution of  $\text{KSeCy}$  is added to  $\text{AuCl}_3\text{Aq}$ ,  $\text{Se}$  is ppd., and the filtrate on evaporation yields small dark-red prisms of the double salt  $\text{AuK}(\text{SeCy})_2$  (Clarke, *B.* 11, 1326).

**Iron selenocyanide.** Not isolated. Crookes (*l.c.*) mentions various reactions which do not yield a definite salt.

**Lead selenocyanide  $\text{Pb}(\text{SeCy})_2$ .** By adding  $\text{KSeCyAq}$  to  $\text{Pb}$  acetate solution, dissolving the pp. in boiling water, filtering (if necessary), and crystallising. Lemon-coloured needles; insol. alcohol; not changed at  $100^\circ$  (*C.*).

**Magnesium selenocyanide.** By dissolving  $\text{MgCO}$  in  $\text{HSeCyAq}$  and evaporating; a gummy non-crystallisable mass; composition undecided.

**Mercury selenocyanide.** Two salts have been isolated,  $\text{Hg}(\text{SeCy})_2$  and  $\text{HgSeCy}$  (Cameron a. Davy, *Tr. Irish Acad.* 27, 148).

**Mercuric selenocyanide  $\text{Hg}(\text{SeCy})_2$** ; a greyish white salt obtained by adding  $\text{KSeCyAq}$  to  $\text{Hg}(\text{C}_2\text{H}_3\text{O}_2)_2\text{Aq}$ . Soluble in  $\text{HgCl}_2\text{Aq}$ , forming  $\text{Hg}(\text{SeCy})_2 \cdot \text{HgCl}_2$ . Not obtained by using  $\text{HgCl}_2$  in place of  $\text{Hg}(\text{C}_2\text{H}_3\text{O}_2)_2$  (Crookes).

**Mercurous selenocyanide  $\text{HgSeCy}$** ; olive green, amorphous; by pp.  $\text{HgNO}_3\text{Aq}$  ly  $\text{KSeCyAq}$ .

**Platinum selenocyanide.** Not isolated. Addition of  $\text{PtCl}_4\text{Aq}$  to an alcoholic solution of  $\text{KSeCy}$  forms a reddish pp.; when this is treated with boiling water part of it dissolves, and the filtrate gives crystals on cooling; these crystals are dissolved in alcohol and re-crystallised; they are the double salt  $\text{K}_2\text{Pt}(\text{SeCy})_4$ ; S.G. 3.877 at  $10^\circ$ , 3.378 at  $12.5^\circ$  (Clarke, *Am. S.* 16, 119).

**Potassium selenocyanide  $\text{KSeCy}$ .** Prepared by dissolving red  $\text{Se}$  (ppd. in the cold) in  $\text{KCyAq}$  and evaporating (Schiellerup, *A.* 109, 125). Also by fusing 1 part  $\text{Se}$  with 3 parts dry  $\text{K}_2\text{FeCy}_2$  in a small retort, digesting with absolute alcohol, passing  $\text{CO}$  through the liquid to decompose  $\text{KCy}$  and  $\text{KNCy}$  and ppt.  $\text{KHCO}_3$ , distilling off the alcohol, dissolving in water, filtering, and crystallising *in vacuo* over  $\text{H}_2\text{SO}_4$  (*C.*). White, needle-shaped deliquescent crystals; melt without change, if out of contact with air (Berzelius); in air decomposes a little above  $100^\circ$  (*C.*).  $\text{KSeCyAq}$  is alkaline to litmus; decomposed by acids with evolution of  $\text{HCy}$  and ppn. of  $\text{Se}$ .  $\text{Cl}$  produces  $\text{CyCl}$  and  $\text{Se}$  (*cf.* Kypke a. Neger, *A.* 115, 207). Several double compounds are described by Cameron a. Davy (*Tr. Irish Acad.* 27, 151);  $\text{X.HgCy}$ ,  $\text{X.HgBr}$ ,  $\text{X.HgI}$ ,  $\text{X.HgCl}$ ,  $\text{X.Hg}(\text{SCy})_2$ .

**Silver selenocyanide  $\text{AgSeCy}$ .** Ppd. on adding  $\text{AgNO}_3\text{Aq}$  to  $\text{KSeCyAq}$ ; if  $\text{NH}_4\text{Aq}$  is present pp. separates in small shining crystals. Blackens in light; insol. in water; sparingly sol. in cold dilute acids; decomposed by hot conc. acids (*C.*).

**Sodium selenocyanide  $\text{NaSeCy}$ .** Small crystals; by neutralising  $\text{HSeCyAq}$  by  $\text{Na}_2\text{CO}_3$  and evaporating *in vacuo* (*C.*).

**Zinc selenocyanide.** Non-deliquescent crystals  $[\text{Zn}(\text{SeCy})_2]$ ; by dissolving  $\text{Zn}$  or  $\text{ZnO}$  in  $\text{HSeCyAq}$  and evaporating (*C.*).

**SULPHOCYANIDES.** (*Rhodanides*. *Sulphocyanates*. *Thiocyanates*.) *Salts of sulphocyanic acid  $\text{HSCN}$ .* For an account of sulphocyanic acid v. **CYANIC (SULPHO) ACID**, p. 303; and for general properties of sulphocyanides v. p. 324. *Disulphocyanides* (salts of  $\text{H}_2\text{C}_2\text{N}_2\text{S}_2$ ) are described in the art. **CYANURATES (METALLIC)** and **SULPHOCYANURATES**, p. 360.

**Aluminium sulphocyanide  $\text{Al}_2\text{O}_3 \cdot x\text{H}_2\text{O}$**  dissolves slowly in  $\text{HSCyAq}$ ; when the solution is evaporated over  $\text{H}_2\text{SO}_4$  a gummy mass is obtained, which may be the neutral salt; if the solution is evaporated at  $100^\circ$   $\text{H}_2\text{S}$  and  $\text{HCy}$  are evolved and yellow flakes (? basic salt) separate (Meitzendorff, *P.* 56, 63).

**Ammonium sulphocyanide  $\text{NH}_4\text{SCy}$ .** H.F.  $[\text{N}, \text{H}^+, \text{S}, \text{Cy}] = 59,100$  (Joannis, *A. Ch.* [5] 26, 510). Produced by decomposing  $\text{Cu}(\text{SCy})_2$  by  $\text{NH}_4\text{HSAq}$ , filtering, and evaporating; also by evaporation of  $\text{NH}_4\text{Aq}$  mixed with alcoholic solution of  $\text{CS}_2$  (Mullon, *Z.* 1861. 64; Zeise, *A.*

47, 86; Claus, *A.* 179, 112). Prepared by digesting the  $\text{HCNAq}$  from 6 parts  $\text{K}_2\text{FeCy}_2$  (by distilling with 3 parts conc.  $\text{H}_2\text{SO}_4$  mixed with 1½ parts water) with the  $\text{NH}_4$  polysulphide solution obtained by saturating 2 parts  $\text{NH}_4\text{Aq}$ , S.G. .95, with  $\text{H}_2\text{S}$ , and adding 2 parts of the same  $\text{NH}_4\text{Aq}$  and 2 parts S.; the liquid is boiled till all  $\text{NH}_4$  sulphide is decomposed with separation of S, filtered, evaporated, and crystallised (about 1½ to 1¾ parts  $\text{NH}_4\text{SCy}$  are obtained) (Liebig, *A.* 61, 126). Large, white, deliquescent plates. S.G. 1.3075 at 13° (Clarke, *J.* 1877, 43). V. sol. water and alcohol; melts at 159° (Reynoso, *A.* 150, 255); and at higher temperature (180°–190°) evolves  $\text{CN}_2$ ,  $\text{H}_2\text{S}$ , and  $\text{NH}_3$ , and leaves guanidin sulphocyanide (Vollhard, *B.* 7, 92; Delitsch, *J. pr.* [2] 8, 240; 9, 1); at 230°–250° thiopressianic acids are formed (Claus a. Seppel, *B.* 7, 92); at still higher temperature mellian is formed, and finally mellone (Vollhard, *J. pr.* [2] 9, 28). Heated for some time nearly to its M.P., thio-urea,  $\text{CS}(\text{NH}_2)_2$  (isomeric with  $\text{NH}_4\text{SCy}$ ), is produced (Vollhard, *B.* 7, 92; Reynoso, *A.* 150, 255). S. 122.1 at 0°, 162.2 at 20°; much heat disappears during solution (Rudorff, *B.* 2, 68; Clowes, *Z.* 1866, 190; Joannis, *A. Ch.* [5] 26, 482). Several metallic oxides, e.g.  $\text{HgO}$ ,  $\text{ZnO}$ ,  $\text{Ag}_2\text{O}$ , dissolve in  $\text{NH}_4\text{SCyAq}$  and form double sulphocyanides (Fleischer, *A.* 179, 225). Combines with  $\text{HgCy}_2$  to form the double compound  $\text{NH}_4\text{SCy.HgCy}_2$  (Clève, *Bl.* [2] 23, 71).

**Arsenic sulphocyanide**  $\text{As}(\text{SCy})_3$ . Produced in very small quantity by heating together  $\text{AsCl}_3$  and  $\text{Pb}(\text{SCy})_2$ ; volatile at c. 400° forming oily drops which solidify to crystals; insol. in all ordinary menstrua; decomposed by water to  $\text{As}_2\text{O}_3$  and  $\text{HSCy}$  (Miguel, *A. Ch.* [5] 11, 311).

**Barium sulphocyanide**  $\text{Ba}(\text{SCy})_2 \cdot 2\text{H}_2\text{O}$ . Formed by neutralising  $\text{HSCyAq}$  by  $\text{BaCO}_3$ , evaporating at 100°, and then over  $\text{H}_2\text{SO}_4$  (Meitzendorff, *P.* 56, 63). Long, lustrous, deliquescent needles; v. sol. alcohol and water. From warm solution of this salt mixed with warm  $\text{H}_2\text{CyAq}$  the double compound  $\text{Ba}(\text{SCy})_2 \cdot \text{HgCy}_2 \cdot 4\text{H}_2\text{O}$  separates on cooling (Clève, *Bl.* [2] 23, 71; cf. Storck a. Stöbel, *D. P. J.* 235, 156).

**Beryllium sulphocyanide** [ $2\text{Be}(\text{SCy})_2$ ]. Prepared by adding  $\text{BeSO}_4$  to  $\text{Ba}(\text{SCy})_2\text{Aq}$  (Toczynsky, *Z.* 1871, 276); or by dissolving  $\text{BeCO}_3$  in  $\text{HSCyAq}$  and crystallising (Hernes, *J. pr.* 97, 465).

**Bismuth sulphocyanide**  $\text{Bi}(\text{SCy})_3$ . By dissolving  $\text{Bi}_2\text{O}_3 \cdot x\text{H}_2\text{O}$  in  $\text{HSCyAq}$ , evaporating, filtering from the yellow basic salt which separates, and evaporating again; dark orange red powder (Meitzendorff, *P.* 56, 63).

**Cadmium sulphocyanide**  $\text{Cd}(\text{SCy})_2$ . White crystals; sp. sol. water; by dissolving  $\text{CdCO}_3$  in  $\text{HSCyAq}$  and evaporating (Meitzendorff, *P.* 56, 63). By dissolving this salt in  $\text{NH}_4\text{Aq}$ , and evaporating with frequent addition of  $\text{NH}_4\text{Aq}$ , the double compound  $\text{Cd}(\text{SCy})_2 \cdot 2\text{NH}_3$  is formed (M.). The double compound  $\text{Cd}(\text{SCy})_2 \cdot 2\text{HgCy}_2 \cdot 4\text{H}_2\text{O}$  is described by Clève (*Bl.* [2] 23, 71).

**Calcium sulphocyanide**  $\text{Ca}(\text{SCy})_2 \cdot 3\text{H}_2\text{O}$ . Prepared like the Ba salt. Crystallises badly; sol. water (Meitzendorff, *P.* 56, 63). From hot solutions of this salt and  $\text{HgCy}_2$ , the double compound  $\text{Ca}(\text{SCy})_2 \cdot 2\text{HgCy}_2 \cdot 8\text{H}_2\text{O}$  crystallises on cooling (Clève, *Bl.* [2] 23, 71; Böckmann, *A.* 22, 163).

**Cerium sulphocyanide**  $\text{Ce}(\text{SCy})_3 \cdot 7\text{H}_2\text{O}$ ; double compound  $\text{Ce}(\text{SCy})_3 \cdot 3\text{HgCy}_2 \cdot 12\text{H}_2\text{O}$  (Jolin, *Bl.* [2] 21, 535).

**Chromium sulphocyanides**. Besides *chromic sulphocyanide*, the acid *chromisulphocyanhydric*,  $\text{H}_2\text{Cr}(\text{SCy})_2$ , is known in aqueous solution, and a series of salts, *chromisulphocyanides*, is derived from it; there are also several *chrom-ammonium sulphocyanides* known.

**Chromic sulphocyanide**  $\text{Cr}(\text{SCy})_3$ . Dark-green, amorphous, deliquescent mass, obtained by dissolving  $\text{Cr}_2\text{O}_3 \cdot x\text{H}_2\text{O}$  in  $\text{HSCyAq}$ , and evaporating over  $\text{H}_2\text{SO}_4$  in *vacuo* (Clasen, *J. pr.* 96, 349).

**Chromisulphocyanhydric acid**, or *chromisulphocyanic acid*,  $\text{H}_2\text{Cr}(\text{SCy})_2\text{Aq}$ ; known only in aqueous solution, which is obtained by decomposing the Pb or Ag salt by  $\text{H}_2\text{S}$ . This solution is dark wine-red and distinctly acid; it decomposes on evaporation to  $\text{HSCyAq}$  and  $\text{Cr}(\text{SCy})_3$  (Rosler, *A.* 111, 185).

**Potassium chromisulphocyanide**  $\text{K}_2\text{Cr}(\text{SCy})_2 \cdot 4\text{H}_2\text{O}$ . Prepared by heating for about 2 hours a fairly conc. solution of 6 parts  $\text{KSCy}$  and 5 parts chrome-alum, pig. by alcohol, filtering, and crystallising from alcohol. Forms almost black crystals, which appear ruby red by transmitted light; loses all  $\text{H}_2\text{O}$  at 110°. Solution of this salt is not ppd. by alkali carbonates or by  $\text{NH}_4\text{HS}$ ; it is ppd. by  $\text{NaOH}$  only on heating; evaporated with  $\text{HClAq}$ ,  $\text{KCl}$  and  $\text{CrCl}_3$  are produced (Rosler, *A.* 141, 185). Besides the K salt the following are described by Rosler (*loc.*):—

$(\text{NH}_4)_2\text{Cr}(\text{SCy})_2 \cdot 8\text{H}_2\text{O}$ ;  $\text{Ba}_2\text{Cr}(\text{SCy})_2 \cdot 16\text{H}_2\text{O}$ ;  $\text{Pb}_2\text{Cr}(\text{SCy})_2 \cdot 4\text{Pb}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$ ;  $\text{Ag}_2\text{Cr}(\text{SCy})_2$ ;  $\text{Na}_2\text{Cr}(\text{SCy})_2 \cdot 7\text{H}_2\text{O}$ .

**Chrom-ammonium sulphocyanides**. The composition of these salts may be expressed by the formula  $2\text{Cr}(\text{SCy})_2 \cdot 4\text{NH}_3 \cdot \text{M}^{\text{II}}(\text{SCy})_2$ , where  $\text{M} = 2\text{NH}_4$ , K, Ag, Cu, or Hg; these salts do not seem to be double compounds, but rather salts of the complex acid  $\text{H}_2(\text{SCy})_2(\text{N}_4\text{H}_6\text{Cr}_2)$ . The acid itself is known in aqueous solution; it is obtained by decomposing the Hg salt by  $\text{H}_2\text{S}$ ; the solution is deep-red, by careful evaporation a red amorphous mass is obtained (Reinecke, *A.* 126, 113).

**The ammonium salt**

$(\text{NH}_4)_2(\text{SCy})_2(\text{N}_4\text{H}_6\text{Cr}_2)$  is obtained by adding powdered  $\text{K}_2\text{Cr}_2\text{O}_7$  to molten  $\text{NH}_4\text{SCy}$  until the mass becomes solid, treating with hot water, and adding pieces of  $\text{NH}_4\text{Cl}$  to the deep-red liquid, when the salt separates in reddish crystals. V. sol. alcohol and ether; by prolonged treatment with water it forms  $\text{NH}_4\text{SCy}$ ,  $\text{Cr}(\text{SCy})_3$ , and  $\text{Cr}_2\text{O}_3$ ; easily decomposed by dilute acids or alkalis (Reinecke, *A.* 126, 113; cf. Morland, *J.* 1860, 162).

The *potassium salt*  $\text{K}_2(\text{SCy})_2(\text{N}_4\text{H}_6\text{Cr}_2)$  is obtained by reacting on the  $\text{NH}_4$  salt by conc.  $\text{KOH}$ , and re-crystallising the compound which separates from hot water.

The *sodium salt* is obtained by a similar process, using  $\text{NaOH}$ . The soluble salts give pps. with salts of many heavy metals; the following have been isolated:—

$\text{Hg}(\text{SCy})_2(\text{N}_4\text{H}_6\text{Cr}_2)$ ,  
 $\text{Ag}_2(\text{SCy})_2(\text{N}_4\text{H}_6\text{Cr}_2)$ .

**Cobalt sulphocyanide**  $\text{Co}(\text{SCy})_2$  (Claus, *A.* 99, 48). Obtained by dissolving  $\text{CoO} \cdot x\text{H}_2\text{O}$  in

$\text{HSCyAq}$ , and evaporating. According to Meitzendorff (P. 56, 63) the salt crystallises with  $\frac{1}{2}\text{H}_2\text{O}$ . Solution in water is rose-red, becoming deep blue by concentration. Alcoholic or ethereal solution becomes blue on dilution; this reaction has been applied for the optical determination of Co (Wolf, *Fr.* 1879, 38). The double compound  $\text{Co(SCy)}_2 \cdot \text{Hg(SCy)}_2$  is known (Clève, *J. pr.* 91, 227; Skey, *J.* 1874, 300).

**Copper sulphocyanides.** *Cuprous sulphocyanide*  $\text{Cu}_2(\text{SCy})_2$  (Meitzendorff, P. 56, 63). Formed by adding  $\text{KSCyAq}$  to  $\text{CuSO}_4\text{Aq}$  reduced by  $\text{FeSO}_4$  or  $\text{SO}_2$ . White powder, insol. water and dilute acids; sol.  $\text{NH}_4\text{Aq}$ . May be used in quantitative estimation of Cu (Rivot, *C. R.* 38, 868; Busse, *Fr.* 1878, 55). *Cupric sulphocyanide*  $\text{Cu(SCy)}$  (Meitzendorff, *l.c.*; Hull, *A.* 76, 93). Black crystalline powder; by adding  $\text{KSCyAq}$  to fairly air-free conc.  $\text{CuSO}_4\text{Aq}$  containing a little  $\text{H}_2\text{SO}_4$ ; decomposed by water, quickly when hot, to  $\text{Cu}_2(\text{SCy})_2$ ,  $\text{HSCy}$ ,  $\text{HCy}$ , and  $\text{H}_2\text{SO}_4$ . Dissolves in  $\text{NH}_4\text{Aq}$ , and gives the double salt  $\text{Cu(SCy)}_2 \cdot 2\text{NH}_3$  (Meitzendorff, *l.c.*).

**Didymium sulphocyanide**  $\text{Di(SCy)}_2 \cdot 6\text{H}_2\text{O}$  (Clève, *Bl.* [2] 21, 248).

**Erbium sulphocyanide**  $\text{Er(SCy)}_2 \cdot 6\text{H}_2\text{O}$  (Clève a. Hoeglund, *Bl.* [2] 18, 197). *Double compound*  $\text{Er(SCy)}_2 \cdot 3\text{HgCy} \cdot 12\text{H}_2\text{O}$  (Clève, *Bl.* [2] 21, 341).

**Gold sulphocyanides**; known only in combination.

**Aurous - potassium sulphocyanide**  $\text{AuSCy.KSCy}$ .  $\text{AuCl}_3\text{Aq}$  is added drop by drop to  $\text{KSCyAq}$  at  $80^\circ$  as long as the pp. dissolves, the liquid is evaporated and crystallised. Straw-yellow prisms; melts at  $100^\circ$ ; decomposed by heat to  $\text{S}$ ,  $\text{CS}_2$ ,  $\text{Au}$ , and  $\text{KSCy}$ . Solution blackens in light; it gives pps. with salts of many heavy metals (Clève, *J. pr.* 91, 14). Addition of  $\text{NH}_4\text{Aq}$  pps. the double compound  $\text{AuSCy.NH}_3$ .

**Auric-potassium sulphocyanide**  $\text{Au(SCy)}_2 \cdot \text{KSCy}$ .  $\text{AuCl}_3\text{Aq}$  is added to excess of  $\text{KSCyAq}$  in the cold (Clève, *J. pr.* 94, 14). Crystallises from warm water in orange-red needles; sol. alcohol and ether. Forms double compounds (Skey, *J.* 1874, 300).

**Auric-sodium sulphocyanide**  $\text{Au(SCy)}_2 \cdot \text{NaSCy}$  (Kern, *J.* 1876, 319).

**Iron sulphocyanide.** *Ferric sulphocyanide*  $\text{Fe(SCy)}_3 \cdot 1\frac{1}{2}\text{H}_2\text{O}$ ; by  $\text{KSCyAq}$  to  $\text{FeCl}_3\text{Aq}$  and evaporating. Small blackish red crystals; v. sol. water, alcohol, and ether. Solution is decolourised by  $\text{NaHCO}_3$  with ppn. of all Fe; not decolourised by  $\text{HClAq}$  (Clève, *J. pr.* 91, 227; cf. Skey, *J.* 1874, 300). *Ferrous sulphocyanide*  $\text{Fe(SCy)}_2 \cdot 1\frac{1}{2}\text{H}_2\text{O}$ . Greenish prisms, by adding  $\text{KSCyAq}$  to  $\text{FeSO}_4\text{Aq}$ ; v. sol. water, alcohol, and ether; unstable (Clans, *A.* 99, 48). Forms a double compound  $\text{Fe(SCy)}_2 \cdot \text{Hg(SCy)}_2$  (Clève, *J. pr.* 91, 227).

**Lanthanum sulphocyanide**  $\text{La(SCy)}_3 \cdot 7\text{H}_2\text{O}$ . *Double compound*  $\text{La(SCy)}_3 \cdot 3\text{HgCy} \cdot 12\text{H}_2\text{O}$  (Clève, *Bl.* [2] 21, 196).

**Lead sulphocyanide**  $\text{Pb(SCy)}_2$ . Yellow lustrous monoclinic crystals; by ppg. neutral  $\text{Pb(C}_2\text{H}_3\text{O}_2)_2\text{Aq}$  by  $\text{KSCyAq}$ . S.G. 3.82 (Schabus, *W. A. B.* 1850, 108). Decomposed by hot water to the basic salt  $\text{PbOH.SCy}$ , which is also obtained by adding basic Pb acetate to  $\text{KSCyAq}$  (Liebig, *P.* 25, 646). H.F. [ $\text{Pb}$ ,  $\text{S}$ ,  $\text{Cy}$ ] = 23,000 (Joannis, *A. Ch.* [5] 26, 640). The double salts  $\text{Pb(SCy)}_2 \cdot \text{PbBr}_2$ ,  $\text{Pb(SCy)}_2 \cdot 6\text{PbBr}_2$ , and

$3\text{Pb(SCy)}_2 \cdot \text{PbI}_2$ , are described by Thorp (*Am.* 10, 229).

**Lithium sulphocyanide**  $\text{LiSCy}$  (Hermes, *J. pr.* 97, 465).

**Magnesium sulphocyanide**  $\text{Mg(SCy)}_2 \cdot 4\text{H}_2\text{O}$ . White deliquescent crystals; by dissolving  $\text{MgCO}_3$  in  $\text{HSCyAq}$  and evaporating (Meitzendorff, P. 56, 63). Forms the double compound  $\text{Mg(SCy)}_2 \cdot 2\text{HgCy} \cdot 4\text{H}_2\text{O}$  by mixing warm solutions of the two salts and allowing to cool (Clève, *Bl.* [2] 23, 71).

**Manganese sulphocyanide**  $\text{Mn(SCy)}_2 \cdot 3\text{H}_2\text{O}$  (Meitzendorff, P. 56, 63). By dissolving  $\text{MnCO}_3$  in  $\text{HSCyAq}$  and evaporating. Loses  $3\text{H}_2\text{O}$  at  $160^\circ$ – $170^\circ$ .

**Mercury sulphocyanides.** *Mercurous sulphocyanide*  $\text{HgSCy}$  (Wöhler, *G. A.* 69, 271). H. F. [ $\text{Hg}$ ,  $\text{S}$ ,  $\text{Cy}$ ] = 18,000 (Joannis, *A. Ch.* [5] 26, 540). White pp. by adding dilute  $\text{KSCyAq}$  to a large excess of very dilute  $\text{HgNO}_3\text{Aq}$  with a little  $\text{HNO}_3$  added; if the solutions are not dilute the pp. is grey and contains  $\text{Hg}$  (Claus, *J. pr.* 15, 401; Hermes, *J. pr.* 97, 465). Sol. in hot  $\text{HClAq}$ , also in  $\text{KSCyAq}$ , with separation of  $\text{Hg}$  (Philipp, *P.* 131, 86). *Mercuric sulphocyanide*  $\text{Hg(SCy)}_2$ . White pp. by mixing  $\text{HgCl}_2\text{Aq}$  or  $\text{Hg(NO}_3)_2\text{Aq}$  and  $\text{KSCyAq}$ ; sol. excess of either salt; v. sl. sol. water, m. sol. alcohol; soluble with decomposition in solutions of chlorides. When  $\text{Hg(SCy)}_2$  is heated it swells up, giving off  $\text{Hg}$  vapour,  $\text{N}$ , and  $\text{CS}_2$ , and leaving a grey mass like graphite, and at a higher temperature forming mellon. This salt is sold under the name of 'Pharaoh's serpents.' (Hermes, *J. pr.* 97, 465; Philipp, *P.* 131, 86.)  $\text{Hg(SCy)}$ , dissolves in some other sulphocyanides forming double sulphocyanides; the following have been isolated:— $\text{Hg(SCy)}_2 \cdot 2\text{NH}_3\text{SCy}$  (Fleischer, *A.* 179, 225);  $\text{Hg(SCy)}_2 \cdot 2\text{KSCy}$  (Hermes, *J. pr.* 97, 465);  $\text{Hg(SCy)}_2 \cdot \text{Zn(SCy)}_2$  (Clève, *J. pr.* 91, 227). Besides these double sulphocyanides  $\text{Hg(SCy)}_2$  forms several double compounds with other salts;  $\text{Hg(SCy)}_2 \cdot 3\text{NH}_3 \cdot \text{H}_2\text{O}$  (Fleischer, *A.* 179, 225);  $\text{Hg(SCy)}_2 \cdot \text{NH}_3 \cdot \text{HgO}$  (Claus, *J. pr.* 15, 401; Philipp, *P.* 131, 86; Fleischer, *l.c.*);  $\text{Hg(SCy)}_2 \cdot 3\text{HgO}$  (Fleischer, *l.c.*);  $\text{Hg(SCy)}_2 \cdot \text{C}_2\text{H}_3\text{O}_2$  (Byk, *J. pr.* [2] 20, 328);  $\text{Hg(SCy)}_2 \cdot \text{KC}_2\text{H}_3\text{O}_2$  (Böckmann, *A.* 22, 153; Claus, *l.c.*; Philipp, *l.c.*).

**Molybdenum sulphocyanide.** Pp. formed by adding conc.  $\text{KSCyAq}$  to a Mo salt is probably  $\text{Mo(SCy)}_4$  (?). Sol. in water or ether with intense dark carmine red colour (Braun, *Fr.* 1863, 36; 1867, 86). Said to form a double compound with  $\text{Hg(SCy)}_2$  (Skey, *C. N.* 30, 25).

**Nickel sulphocyanide**  $\text{Ni(SCy)}_2 \cdot \frac{1}{2}\text{H}_2\text{O}$ ; yellow crystalline powder; obtained by evaporating solution of  $\text{NiO}$  in  $\text{HSCyAq}$  (Meitzendorff, P. 56, 63). Dissolves in  $\text{N}_2\text{I}_2\text{Aq}$ , and solution evaporated on water-bath gives blue efflorescent crystals of the double compound  $\text{Ni(SCy)}_2 \cdot 4\text{NH}_3$ ; decomposed by water to  $\text{NH}_4\text{Aq}$  and  $\text{NiO}$  (Meitzendorff, *l.c.*). Also forms a double compound with  $\text{Hg(SCy)}_2$ , viz.  $\text{Ni(SCy)}_2 \cdot \text{Hg(SCy)}_2 \cdot 2\text{H}_2\text{O}$  (Clève, *J. pr.* 91, 227).

**Palladium sulphocyanides.** None certainly isolated; if a simple sulphocyanide of Pd exists it is very soluble in water (v. Porrett, *T.* 1814, 627). By dissolving  $\text{PdCl}_2 \cdot 2\text{KCl}$  and  $\text{KSCy}$  in water and crystallising, a double sulphocyanide of Pd and K is obtained; other double palladium sulphocyanides are also said to be formed by re-

actions similar to those whereby sulphocyanoplatinum compounds are produced; the composition of these salts is not yet finally decided, the data are meagre (v. Croft, *C. N.* 16, 53).

**Phosphorus sulphocyanide**  $\text{P}(\text{SCy})_3$ , v. Phosphorus.

**Platinum sulphocyanides.** The reddish-brown solid obtained in the reaction between some of the double Pt sulphocyanides, e.g.  $\text{K}_2\text{Pt}(\text{SCy})_2$  and  $\text{Cl}$  or  $\text{HNO}_3\text{Aq}$ , is probably *platino-sulphocyanide*,  $\text{Pt}(\text{SCy})_2$  (Buckton, *C. J.* 7, 22). *Platinic sulphocyanide* has not been isolated. Many double compounds of  $\text{Pt}(\text{SCy})_2$  and  $\text{Pt}(\text{SCy})_4$  are known, but they are better regarded as salts of the acids  $\text{H}_2\text{Pt}(\text{SCy})_2$  and  $\text{H}_2\text{Pt}(\text{SCy})_4$ , both of which are known in aqueous solution; the salts in question are generally called *sulphocyanoplatinites* and *sulphocyanoplatinates*, or sometimes *platino-sulphocyanides*. The K salts are formed by reaction between  $\text{KSCy}$  and  $\text{PtCl}_4\text{Aq}$  or  $\text{PtCl}_2\text{Aq}$ ; the salts of the heavy metals are formed from the K salts by double decomposition. Both series of salts are decomposed by  $\text{Cl}$  or  $\text{HNO}_3\text{Aq}$  with formation of  $\text{HCy}$ ,  $\text{H}_2\text{SO}_4(\text{HCl})$ ,  $\text{K}_2\text{SO}_4(\text{KNO}_3)$ , and separation of a brownish-red solid which is probably  $\text{Pt}(\text{SCy})_2$ .  $\text{NH}_3\text{Aq}$  reacts with salts of both series to form *platiosammonium sulphocyanide* ( $\text{N}_2\text{H}_5\text{Pt}_2\text{SCy}$  (q. v.)). The sulphocyanoplatinum compounds have been chiefly investigated by Buckton (*C. J.* 7, 22).

**Sulphocyanoplatinous acid**  $\text{H}_2\text{Pt}(\text{SCy})_2\text{Aq}$ . (*Platinoso-sulphocyanic acid*, *Platinoso-sulphocyanhydric acid*.) Known only in aqueous solution, which is obtained by carefully adding dilute  $\text{H}_2\text{SO}_4\text{Aq}$  to the Ba salt; the solution soon decomposes even by evaporation *in vacuo*, giving  $\text{HSCyAq}$  and a pp. containing Pt.

**Ammonio-platinous sulphocyanoplatinite or platinoso-sulphocyanide** ( $\text{N}_2\text{H}_5\text{Pt}_2\text{SCy}$ ). (*Diammonio-platiosammonium sulphocyanoplatinite*, ( $\text{N}_2\text{H}_5(\text{NH}_4)_2\text{Pt}_2\text{SCy}$ .) Obtained by adding  $\text{KSCyAq}$  to diplatiosammonium chloride,  $\text{N}_2\text{H}_5(\text{NH}_4)_2\text{Pt}_2\text{Cl}_2$ ; buff pp.; insol. in water and alcohol, sol. in dilute  $\text{HClAq}$ ; when heated it is decomposed, burning like tinder, and leaves Pt. This salt seems to be polymeric with *platiosammonium sulphocyanide*, ( $\text{N}_2\text{H}_5\text{Pt})_2\text{SCy}$  (q. v.).

**Potassium sulphocyanoplatinite or platinoso-sulphocyanide**  $\text{K}_2\text{Pt}(\text{SCy})_2$ . Prepared by dissolving equal parts of  $\text{PtCl}_2$  and  $\text{KSCy}$  in as small a quantity as possible of hot water, and crystallising from alcohol the salt which separates. Also by adding  $\text{PtCl}_2\cdot 2\text{KCl}$  in small successive quantities to conc.  $\text{KSCyAq}$ , crystallising from alcohol, pressing between paper, and re-crystallising from water. Red microscopic crystals; six-sided prisms;  $\text{S. } 40$  at  $15-5^\circ$ ; v. sol. in alcohol. Non-deliquescent; not changed at  $100^\circ$  if dry; decomposed by  $\text{NH}_3\text{Aq}$  to ( $\text{N}_2\text{H}_5\text{Pt})_2\text{SCy}$  and  $\text{KSCyAq}$ .

**Silver sulphocyanoplatinite or platinoso-sulphocyanide**  $\text{Ag}_2\text{Pt}(\text{SCy})_2$ . White eury pp. by adding  $\text{AgNO}_3\text{Aq}$  to solution of the K salt. Partly soluble in  $\text{NH}_3\text{Aq}$  with decomposition; sol. in  $\text{KSCyAq}$ .

**Sulphocyanoplatinic acid or platinoso-sulphocyanic acid** (*Platinoso-sulphocyanhydric acid*)  $\text{H}_2\text{Pt}(\text{SCy})_2\text{Aq}$ . Known only in aque-

ous solution, which is obtained by decomposing the Pb salt by  $\text{H}_2\text{S}$ ; decomposes when evaporated, even *in vacuo*; dark-red liquid with acid taste; decomposes carbonates and dissolves Zn evolving H.

**Ammonium sulphocyanoplatinate or platino-sulphocyanide** ( $\text{NH}_4)_2\text{Pt}(\text{SCy})_2$ . Carmine-red six-sided tables; formed by boiling 1 part ( $\text{NH}_4)_2\text{SO}_4$  with  $1\frac{1}{2}$  parts  $\text{K}_2\text{Pt}(\text{SCy})_2$  in conc. solution, separating ( $\text{NH}_4)_2\text{SO}_4$  and  $\text{K}_2\text{SO}_4$  by adding alcohol, and re-crystallising the salt from warm water. Aqueous solution is decomposed by boiling, giving off  $\text{HSCy}$ .

**Barium sulphocyanoplatinate or platino-sulphocyanide**  $\text{BaPt}(\text{SCy})_2$ . Red needles; sol. in water and alcohol; by reaction between excess of  $\text{BaCl}_2\text{Aq}$  and  $\text{K}_2\text{Pt}(\text{SCy})_2$ , evaporating and dissolving in alcohol.

**Cupric sulphocyanoplatinate or platino-sulphocyanide**; green pp. by adding  $\text{K}_2\text{Pt}(\text{SCy})_2\text{Aq}$  to  $\text{CuSO}_4\text{Aq}$ , probably  $\text{CuPt}(\text{SCy})_2$ ; becomes black when liquid is boiled; sol. in  $\text{NH}_3\text{Aq}$ , reppd. by  $\text{HClAq}$ .

**Iron sulphocyanoplatinate or platino-sulphocyanides.** The ferrous salt  $\text{FePt}(\text{SCy})_2$  is a black crystalline pp., insol. in water and alcohol, obtained by adding slightly acidulated  $\text{FeSO}_4\text{Aq}$  to conc.  $\text{K}_2\text{Pt}(\text{SCy})_2\text{Aq}$ . The ferric salt is prepared by using  $\text{FeCl}_3\text{Aq}$  in place of  $\text{FeSO}_4\text{Aq}$  and boiling; probably  $\text{Fe}_2\text{Pt}(\text{SCy})_2$ .

**Lead sulphocyanoplatinate or platino-sulphocyanide**  $\text{PbPt}(\text{SCy})_2$ ; golden-yellow hexagonal plates, obtained by mixing conc.  $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2\text{Aq}$  and conc.  $\text{K}_2\text{Pt}(\text{SCy})_2$ , washing with cold water, and crystallising from alcohol; decomposed by hot water. The basic salt  $\text{PbPt}(\text{SCy})_2\cdot\text{PbO}$  is formed as a red pp. by ppg. basic Pb acetate solution with conc.  $\text{K}_2\text{Pt}(\text{SCy})_2\text{Aq}$ .

**Mercurous sulphocyanoplatinate or platino-sulphocyanide**  $\text{Hg}_2\text{Pt}(\text{SCy})_2$ ; yellow pp. by adding  $\text{HgNO}_3\text{Aq}$  to  $\text{K}_2\text{Pt}(\text{SCy})_2\text{Aq}$ .

**Potassium sulphocyanoplatinate or platino-sulphocyanide**  $\text{K}_2\text{Pt}(\text{SCy})_2$ . Prepared by adding 2 pts.  $\text{KPtCl}_6$  to a warm solution of  $2\frac{1}{2}$  pts.  $\text{KSCy}$ , heating nearly to boiling, filtering, and allowing to crystallise; the crystals are dissolved in boiling alcohol (to separate  $\text{KCl}$ ), and the liquid is passed through a filter which is kept warm. Also produced by adding  $\text{PtCl}_4\text{Aq}$  to conc.  $\text{KSCyAq}$  at  $70^\circ-80^\circ$ , and allowing to cool. Deep carmine-red, six-sided prisms; permanent in air at ordinary temperatures;  $\text{S. c. } 8\frac{1}{2}$  at  $60^\circ$ ,  $\text{S. } 8$  much greater at  $100^\circ$ . Crystallises with  $2\text{H}_2\text{O}$  according to Gmelin (cf. Wyrbow, *Bl.* [2] 33, 402). Heated to redness gives  $\text{KSCy}$ , Pt, and gaseous products. Decomposed by hot  $\text{H}_2\text{SO}_4$  or  $\text{HClAq}$ . With  $\text{HNO}_3\text{Aq}$  or  $\text{Cl}$  probably gives  $\text{Pt}(\text{SCy})_2$ . Reacts with  $\text{NH}_3\text{Aq}$  or  $(\text{NH}_4)_2\text{CO}_3\text{Aq}$  to form  $\text{K}_2\text{SO}_4$ ,  $\text{KSCy}$ ,  $\text{NH}_4\text{Cy}$ ,  $\text{NH}_4\text{SCy}$ , and ppt. yellow needles of *platiosammonium sulphocyanide* ( $\text{N}_2\text{H}_5\text{Pt}_2\text{SCy}$  (q. v.)).

**Silver sulphocyanoplatinate or platino-sulphocyanide**  $\text{Ag}_2\text{Pt}(\text{SCy})_2$ . Orange-yellow pp. by mixing  $\text{AgNO}_3\text{Aq}$  with  $\text{K}_2\text{Pt}(\text{SCy})_2\text{Aq}$ . Forms a double salt  $\text{Ag}_2\text{Pt}(\text{SCy})_2\cdot 2\text{KSCy}$ .

**Sodium sulphocyanoplatinate or platino-sulphocyanide**  $\text{Na}_2\text{Pt}(\text{SCy})_2$ . Garnet-coloured tablets; obtained by decompos-

ing the Pb salt by  $\text{Na}_2\text{SO}_4\text{aq}$ ; sol. water and alcohol.

**Platosammonium sulphocyanide** ( $\text{N}_2\text{H}_4\text{Pt}$ ).  $2\text{SCy}$ . This salt is obtained by decomposing potassium platino-sulphocyanide  $\text{K}_2\text{Pt}(\text{SCy})_4$  (v. *supra*) by  $\text{NH}_4\text{aq}$  or  $(\text{NH}_4)_2\text{CO}_3\text{aq}$ , collecting the crystals which separate, washing them with cold water, and recrystallising from alcohol. It is also produced when  $\text{NH}_4\text{aq}$  reacts with potassium platino-sulphocyanide  $\text{K}_2\text{Pt}(\text{SCy})_4$ , or by mixing 1 pt.  $\text{KSCy}$  with 16 pts. platosammonium chloride  $\text{N}_2\text{H}_4\text{PtCl}_4$  in aqueous solution, heating nearly to boiling, adding an equal volume of alcohol, filtering hot, and allowing to cool. Straw-yellow needles; melts at  $100^\circ$ – $110^\circ$ ; decomposes at c.  $180^\circ$ , giving off  $\text{NH}_3$  and  $\text{HCy}$ , and also  $\text{SO}_2$  if in air, and leaving Pt. Sparingly sol. cold water, more sol. alcohol. Not acted on by dilute  $\text{HClaq}$  or  $\text{H}_2\text{SO}_4\text{aq}$ . Aqueous solution is decomposed on cooling, evolving  $\text{NH}_3$  (Buckton, *C. J.* 7, 22). The salt described as *ammonio-platinous platino-sulphocyanide* ( $\text{N}_2\text{H}_4[\text{NH}_4]\text{Pt}(\text{SCy})_4$  (v. p. 351) is probably polymeric with platosammonium sulphocyanide.

**Potassium sulphocyanide**  $\text{KSCy}$ . H.F. [ $\text{K}_2\text{S}_2\text{Cy}_2$ ] = 87,800 (Joannis, *A. Ch.* [5] 26, 182).

**Formation**.—1. By fusing 1 pt. dry  $\text{K}_2\text{FeCy}_6$  with 3 pts.  $\text{K}_2\text{S}_2\text{O}_8$  (Fröhde, *P.* 119, 317).—2. By heating  $\text{NH}_4\text{SCy}$  with  $\text{KOHaq}$  or  $(\text{NH}_4)_2\text{CS}$ , with  $\text{KSAq}$  (Gélis).—3. By adding a mixture of S, C, and  $(\text{NH}_4)_2\text{SO}_4$  to a molten mixture of KOH and S (Fleck, *D. P. J.* 169, 209) [ $(\text{NH}_4)_2\text{SO}_4 + \text{C} + \text{S} = \text{NH}_4\text{SCy} + \text{SO}_2 + 2\text{H}_2\text{O}$ ; and  $2\text{NH}_4\text{SCy} + \text{K}_2\text{S} = 2\text{KSCy} + (\text{NH}_4)_2\text{S}$ ].—4. An aqueous solution of  $\text{KC}_y$  (65 pts.) is digested with S (32 pts.) until S is all dissolved (Wiggers, *A.* 29, 319).

**Preparation**.—A mixture of 32 pts. S with 17 pts.  $\text{K}_2\text{CO}_3$  is heated until it melts, 46 pts. dry  $\text{K}_2\text{FeCy}_6$  are added, and heating is continued until the mass fuses quietly and a little taken out does not give the reactions of ferrocyanide; temperature is then raised for a little to change any  $\text{K}_2\text{S}_2\text{O}_8$  into  $\text{K}_2\text{SO}_4$ ; the cold mass is extracted with water, and the liquid is neutralised by  $\text{H}_2\text{SO}_4\text{aq}$ ; the liquor is evaporated to dryness, the residue is boiled with alcohol, the alcoholic solution is filtered and crystallised (Henneberg, *A.* 73, 230; cf. Liebig, *A.* 50, 345; 51, 288; Babcock, *Z.* 1896, 666; Fröhde, *P.* 119, 317).

**Properties**.—Long, white, striated prisms, resembling nitre. S.G. 1.886–1.906 (Bödeker, *J.* 1860, 17). S. 177.2 at  $0^\circ$ , 217 at  $20^\circ$  (Rüdorff, *B.* 2, 68). By dissolving 150 pts. of the salt in 100 pts. water at  $10.8^\circ$ , temperature falls to  $-23.7^\circ$  (Rüdorff, *B.* 2, 68). Joannis (*L. Ch.* [5] 26, 482) gives the heat of solution [ $\text{KSCy}, \text{aq}$ ] = -6100. Melts at  $161.2^\circ$  (Pohl, *J.* 1851, 59). The molten salt becomes brown, then green, finally indigo blue, but on cooling it again goes white (Nöllner, *P.* 98, 189). Non-poisonous (Wöhler a. Frerichs, *A.* 65, 342; Hermes, *J. pr.* 97, 465). According to Berzelius (*S.* 31, 42), when  $\text{KSCy}$  is heated in moist air it evolves  $\text{CO}_2$  and  $\text{NH}_3$  and  $\text{K}_2\text{S}$  remains.  $\text{KSCyAq}$  slowly decomposes, quickly on boiling, evolving  $\text{NH}_3$  (Vogel, *S.* 23, 15).

**Reactions**.—1. *Chlorine* passed into melted  $\text{KSCy}$  forms  $\text{S}_2\text{Cl}_2$  and  $\text{Cy}_2\text{Cl}_2$  (Liebig, *P.* 15, 548;

34, 576). Cl passed into fairly conc.  $\text{KSCyAq}$  forms pseudosulphocyanogen  $\text{C}_3\text{N}_2\text{HS}_3$ ; with excess of Cl,  $\text{NH}_3$ ,  $\text{H}_2\text{SO}_4$ ,  $\text{HCl}$ , and  $\text{CO}_2$  are produced (Liebig, *A.* 39, 215; 50, 337; Völkell, *A.* 43, 97; Parnell, *P.* 17, 249).—2. Conc. *nitric acid* ppts.  $\text{C}_3\text{N}_2\text{HS}_3$  (Liebig; Völkell).—3. *Potassium permanganate, manganese dioxide, or lead peroxide* oxidises the S of  $\text{KSCy}$  to  $\text{H}_2\text{SO}_4$  (Hadow, *C. J.* 11, 174).—4. Molten  $\text{KSCy}$  reacts violently with *hydrochloric acid gas*, forming  $\text{HCy}$ ,  $\text{CS}_2$ , and  $\text{NH}_4\text{Cl}$  (Liebig, *l.c.*).—5. Heated gently with *phosphorus pentachloride*  $\text{CyCl}_5$ ,  $\text{KCl}$ , and  $\text{PSCl}_3$  are produced; at a higher temperature the products vary (Schiff, *A.* 106, 116).—6. Heated with iron  $\text{FeS}$ ,  $\text{K}_2\text{S}$ , and  $\text{K}_2\text{FeCy}_6$  are formed (Gélis, *Rep. Chim. App.* 1862, 370).—7.  $\text{KSCyAq}$  *electrolysed* gives  $\text{H}_2\text{SO}_4$ ,  $\text{SO}_2$ ,  $\text{HCy}$  and S (Schlagdenhauffen, *J. Ph.* [3] 49, 100).

**Combination**.—With *mercuric cyanide* and *iodide* to form  $\text{KSCy.HgCy}_2.2\text{H}_2\text{O}$  (Bockmann, *A.* 22, 153; Clève, *Bl.* [2] 23, 71; Philipp, *P.* 131, 86);  $2\text{KSCy.HgI}_2.2\text{H}_2\text{O}$  (Philipp, *l.c.*).

**Silicon sulphocyanide**  $\text{Si}(\text{SCy})_4$  v. *Silicon*.

**Silver sulphocyanide**  $\text{AgSCy}$ . H.F. [ $\text{Ag}_2\text{S}_2\text{Cy}_2$ ] = 16,500 (Joannis, *A. Ch.* [5] 26, 540). White curdy pp. by adding  $\text{KSCyAq}$  to  $\text{AgNO}_3\text{aq}$ . Blackens in light. Insol. water and dilute acids; sol.  $\text{NH}_4\text{aq}$  and alkali sulphocyanides, also in  $\text{HgNO}_3\text{aq}$  (Wackendorf, *A.* 41, 317). Addition of  $\text{NH}_4\text{aq}$  to a solution of  $\text{AgSCy}$  in  $\text{NH}_4\text{SCy}$  ppts. shining tablets of the *double compound*  $\text{AgSCy.NH}_3$ ; loses all  $\text{NH}_3$  by treatment with water (Gmel, *W. A. B.* 60, 474; Weith, *Z.* 1869, 310; cf. Gössmann, *A.* 100, 76). Solution of  $\text{AgSCy}$  in hot  $\text{KSCyAq}$  on cooling deposits the *double salt*  $\text{AgSCy.KSCy}$ ; decomposed by water (Hull, *A.* 76, 33). The *double salt*  $\text{AgSCy.NH}_3\text{SCy}$  is also known (Gössmann, *A.* 100, 76; Fleischer, *A.* 179, 225).

**Sodium sulphocyanide**  $\text{NaSCy}$ . H.F. [ $\text{Na}_2\text{S}_2\text{Cy}_2$ ] = 77,100 (Joannis, *A. Ch.* [5] 26, 510). Prepared by neutralising  $\text{HSCyAq}$  by  $\text{Na}_2\text{CO}_3$ , evaporating, and crystallising from alcohol. Also by heating 1 pt.  $\text{K}_2\text{FeCy}_6$  with 3½ pts. dry  $\text{Na}_2\text{S}_2\text{O}_8$ , and dissolving out with hot alcohol (Fröhde, *P.* 119, 317; Meitzendorf, *P.* 56, 63). Very deliquescent rhombic plates; e. sol. alcohol. Forms the *double compound*  $\text{NaSCy.HgCy}_2$  (Clève, *Bl.* [2] 23, 71).

**Strontium sulphocyanide**  $\text{Sr}(\text{SCy})_2.3\text{H}_2\text{O}$ . Prepared by neutralising  $\text{HSCyAq}$  with  $\text{SrCO}_3$ , and evaporating at  $100^\circ$ , and then over  $\text{H}_2\text{SO}_4$  (Meitzendorf, *P.* 56, 63). Gives off  $3\text{H}_2\text{O}$  at  $100^\circ$ , and begins to decompose at  $160^\circ$ – $170^\circ$ . Forms the *double compound*  $\text{Sr}(\text{SCy})_2.2\text{HgCy}_2.4\text{H}_2\text{O}$  (Clève, *Bl.* [2] 23, 71).

**Thallous sulphocyanide**  $\text{TlSCy}$ . Small shining needles; by mixing  $\text{Tl}_2\text{CO}_3\text{aq}$  with  $\text{KSCyAq}$  (Kuhlmann, *J. pr.* 88, 175; Hermes, *J. pr.* 97, 465). For crystalline form v. Miller (*Pr.* 14, 455). Forms a double salt with  $\text{KSCy}$  (Carstanjen, *J. pr.* 102, 129).

**Tin sulphocyanide**. The *stannous salt*  $\text{Sn}(\text{SCy})_2$  is obtained by heating freshly ptd.  $\text{SnO}_2.\text{H}_2\text{O}$  in  $\text{HSCyAq}$ , filtering, boiling, filtering again from  $\text{SnO}$ , and evaporating. Citron-yellow crystals; sol. water and alcohol; aqueous solution reflects blue light (Clasen, *J. pr.* 96, 319). *Stannic hydrate* scarcely dissolves in  $\text{HSCyAq}$ .

**Uranium sulphocyanide**  $\text{U}(\text{SCy})_6$ . Dark green mass, by dissolving uranous hydrate in

on by alkyl iodides, thus  $\text{CH}_3\text{I}$  gives rise to  $\text{CN}\cdot\text{CH}(\text{CH}_3)\cdot\text{CO}_2\text{Et}$  (194\*). V.D. 4-84;  $\text{C}_2\text{H}_5\text{I}$  gives  $\text{CN}\cdot\text{CH}(\text{C}_2\text{H}_5)\cdot\text{CO}_2\text{Et}$  (204\*). V.D. 4-68;  $\text{C}_3\text{H}_7\text{I}$  gives  $\text{CN}\cdot\text{CH}(\text{C}_3\text{H}_7)\cdot\text{CO}_2\text{Et}$  (215\*-220\*).  $\text{C}_6\text{H}_5\text{CO}_2\text{Et}$  acts easily upon the Na derivative, giving  $\text{CN}\cdot\text{CH}(\text{CO}_2\text{Et})_2$ . The mono-chlor- and mono-bromo-derivatives are formed with remarkable neatness.  $\text{CN}\cdot\text{CHCl}\cdot\text{CO}_2\text{Et}$  is a colourless

liquid, with a pungent odour (190°). V.D. 5.11 (Henry, *C. R.* 104, 1618; Haller, *Bl.* [2] 48, 27).

The following ethers have been obtained by the action of Na and ethyl or methyl cyanacetate upon the corresponding diazo-chlorides:—

*Methyl benzene-azo-cyanacetate*

$C_6H_5.N_2.CH(CN).CO_2Me$ . [86°].

*Ethyl benzene-azo-cyanacetate*

$C_6H_5.N_2.CH(CN).CO_2Et$ . [125°].

*Methyl o-toluene-azo-cyanacetate*

$C_6H_4.Me.N_2.CH(CN).CO_2Me$ . [167°].

*Methyl p-toluene-azo-cyanacetate*

$C_6H_4.Me.N_2.CH(CN).CO_2Me$ . [133°].

*Ethyl o-toluene-azo-cyanacetate*

$C_6H_4.Me.N_2.CH(CN).CO_2Et$ . [126°].

*Ethyl p-toluene-azo-cyanacetate*

$C_6H_4.Me.N_2.CH(CN).CO_2Et$ . [74°] (Haller, *C. R.* 106, 1171–1174).

*Amide*  $CN.CH_2.CONH_2$ . [118°]. Formed by dissolving cyano-acetic ether in aqueous ammonia, and allowing the solution to evaporate spontaneously. Crystallises from alcohol in small needles (Henry, *C. R.* 104, 1618).

*Acetyl-cyano-acetic acid*

$CH_2.CO.CH(CN).CO_2H$ .

*Methyl ether*  $MeA'$ . [47°]. From

$CH_2.CO.CHNa.CO_2Me$  and cyanogen chloride in  $MeOH$  (Haller a. Held, *C. R.* 106, 210). Also from  $CN.CHNa.CO_2Me$  and acetyl chloride. —  $Ca(C_2H_5NO_2)_2.6aq$ : efflorescent crystals.

*Ethyl ether*  $EtA'$ . Formed similarly; v.

CYANO-ACETO-ACETIC ETHER.

*Propionyl-cyano-acetic ether*

$CH_3.CH_2.CO.CH(CN).CO_2Et$ . (160°) at 50 mm. —  $Ca(C_2H_5NO_2)_2.2aq$ .

*n-Butyryl-cyano-acetic ether*

$Pr.CO.CH(CN).CO_2Et$ . (171°) at 66 mm. —  $CaA', 2aq$ . —  $BaA', 3\frac{1}{2}aq$  (Haller, *C. R.* 106, 1085).

*Isobutyryl-cyano-acetic ether*

$Pr.CO.CH(CN).CO_2Et$ . (173°) at 85 mm. —  $CaA', 2aq$ .

*Benzoyl-cyano-acetic ether* v. CYANO BENZOYL ACETIC ACID.

*o-Toluylyl-cyano-acetic ether*

$C_6H_4.Me.CO.CH(CN).CO_2Et$ . [35°]. Prisms (Haller, *C. R.* 107, 104). —  $CaA', 4aq$ .

*Phenyl-acetyl-cyano-acetic ether*

$CH_3.Ph.CO.CH(CN).CO_2Et$ . Oil.

*Cinnamyl-cyano-acetic ether*. [104°].

*Di-cinnamyl-cyano-acetic ether*

$(PhCH:CH.CO)_2C(CN).CO_2Et$ . Silky needles.

**CYANO-ACETIC ALDEHYDE**  $CH_2(CN).CHO$ . (72°). S.G. 1.881. V.D. 2.33. Formed by the action of  $AgCN$  as an alcoholic solution of iodo-acetic-aldehyde. Colourless mobile liquid. Miscible with most solvents. It does not solidify at  $-20^\circ$ . It reduces Fehling's solution, forms a compound with  $NaHSO_3$ , and is resinified by  $NaHO$  and  $HCl$ .  $HNO_3$  oxidises it to cyano-acetic acid. It forms with aniline a base [118°] (Chantard, *C. R.* 106, 1167–1169).

**CYANO-ACETO-ACETIC ETHER**

$CH_2.CO.CH(CN).CO_2Et$ . [27°]. (119°) at 20 mm. Formed by the action of potassium cyanide on chloro-aceto-acetic ether; the salt  $CN.CH_2.C(OK):CH.CO_2Et$  being also formed in small quantity (James, *A.* 240, 61; *C. J.* 51, 287; *C. J. Proc.* 3, 25). Formed also by treating sodium aceto-acetic ether with cyanogen chloride, and from cyano-acetic ether and  $AcCl$

(Haller a. Held, *Bl.* [2] 47, 888; *C. R.* 95, 285; 104, 1627; 105, 115).

*Properties*.—Silky needles, cannot be distilled. Insol. water, sol. alcohol and ether. Gives a characteristic red colouration with  $FeCl_3$ . Decomposed by boiling alkalis into acetic acid,  $CO_2$ , and ammonia.

*Salts*.— $NaC_2H_3NO_3$ : crystals (from alcohol).  $KA'$ : needles (from alcohol); insol. ether and benzene. —  $CaA', 3aq$ : monoclinic crystals (from alcohol).

**CYANO-ACETONE**  $C_2H_3NO$  i.e.

$CH_2.CO.CH_2.CN$ . (c. 125°). From chloro acetone and  $KCy$  in dilute alcohol (Matthews a. Hodgkinson, *B.* 15, 2679). Converted by alcohol and  $HCl$  into aceto-acetic ether.

*Isomeride*. [166°]. From chloro-acetone and aqueous  $KCN$  (Glutz, *J. pr.* [2] 1, 141; cf. Bender, *B.* 4, 518). Very volatile crystals. Forms a crystalline compound with  $HI$ .

**$\alpha$ -CYANO-ACETOPHENONE** v. BENZOYL-ACETONITRILE.

*p*-Cyano-acetophenone  $\alpha$

$[4:1]C_6H_4(CN).CO.CH_3$ . [61°]. From *p*-amido-acetophenone by displacing  $NH_2$  by  $Cy$  (Ahrens, *B.* 20, 2955). Needles (from dilute alcohol). Boiling alcoholic  $KOH$  converts it into aceto-phenone *p*-carboxylic acid (*q. v.*).

*Oxim*  $C_6H_4(CN).C(NOH).CH_3$ . [160°].

**CYANO-ACETYL BROMIDE**  $CH_2(CN).COBr$ . Appears to be formed, together with the isomeric bromo-acetyl cyanide, by heating  $AgCN$  with bromo-acetic acid and chloroform (Hübner, *A.* 124, 315; 131, 66). Needles (from ether or chloroform). Converted by  $KOH$  into cyano-acetic and malonic acids.

**CYANO-ACETYL-DI-METHYL-UREA**

$NIIMe.CO.NMe.CO.CH_2.CN$ . [above 260°]. Prepared by the action of cyano-acetyl chloride on dimethylurea (Mulder, *B.* 12, 466).

**CYANO-ACETYL-UREA**

$NH_2.CO.NH.CO.CH_2.CN$ . [200°–210°]. Sl. sol. water and alcohol. Prepared by the action of cyano-acetyl chloride on urea (Mulder, *B.* 12, 465; *Bl.* [2] 29, 531).

**CYANO-ANGELIC ETHER**

$C_6H_4.CH(CN).CO_2Et$ . (c. 218°). From sodium cyano-acetic ether and allyl iodide (Henry, *C. R.* 104, 1618).

**DI-CYANO-BENZENES** v. *Nitriles of ISOPHTHALIC and TEREPHTHALIC ACIDS.*

**$\alpha$ -CYANO-BENZOIC ACID**  $C_6H_4NO$  i.e.

$C_6H_4(CN).CO_2H$ . *Semi-nitrile of phthalic acid*. Appears to be formed from *o*-amido-benzoic acid by the diazo-reaction, but changes spontaneously into the isomeric phthalimide (Sandmeyer, *B.* 18, 1499).

*Ethyl ether*  $A'Et$ : [70°]; needles; v. sol. alcohol, ether, &c., sl. sol. hot water. Obtained from anthranilic ether by diazotisation and treatment with  $Cu_2(CN)_2$  (Müller, *B.* 19, 1498).

*m*-Cyano-benzoic acid  $C_6H_4(CN)CO_2H$  [1.8]. [217°].

*Formation*.—By the action of a hot solution of cuprous potassium cyanide upon *m*-diazo-benzoic chloride (Sandmeyer, *B.* 18, 1498).

*Properties*.—Microscopic needles. V. e. sol. ether, alcohol, and hot water. Gives isophthalic acid on saponification. By distillation of the  $Ca$  salt with lime benzonitrile is formed. By  $HNO_3$  it is oxidised to isophthalic acid. By alcoholic  $H_2S$

It is converted into the acid  $C_4H_7O_2N$ , probably  $C_4H_7(CO_2H)(CNH).S.C(NH).C_4H_7(CO_2H)$  [199°] whence tin and HCl give  $\omega$ -imido-*m*-di-toluic acid. By treatment with fuming sulphuric acid and pouring the mixture into water it yields  $C_4H_7O_2N$ , probably  $C_4H_7(CO_2H)(CNH).O.C(NH).C_4H_7(CO_2H)$ . [above 300°].

**Salts.**— $C_4H_7(CN).CO_2Ag$ : insoluble pp.— $A_2Ca$  3aq: crystals, sol. hot water.— $A_2Ba$  3½aq: soluble crystals.— $A_2Zn$ : white pp.

**Methyl ether**  $A'Me$ : [65°]; crystals; v. sl. sol. water, v. sol. alcohol, ether, &c.

**Ethyl ether**  $A'Et$ : [56°]; crystals; nearly insol. water.

**Amide**  $C_4H_7(CN).CONH_2$ : [above 300°]; v. sol. alcohol and ether, insol. water.

**Amidoxim**  $C_4H_7(CO_2H)(CNH_2).NOH$ : [198°]; crystalline. Formed by the action of hydroxylamine upon *m*-cyano-benzoic acid (Brönne, *B.* 20, 524; cf. Muller, *B.* 19, 1494).

***p*-Cyano-benzoic acid**  $C_6H_4(CN)CO_2H$  [1:4]. Formed by the action of a hot aqueous solution of cuprous potassium cyanide upon *p*-diazo-benzoic chloride (Sandmeyer, *B.* 18, 1496). Quickly changes into terephthalamic acid.

**Ethyl ether**  $A'Et$ : [54°]; needles; v. sol. alcohol and ether (Müller, *B.* 18, 2485).

#### ISO-CYANO-BENZOPHENONE

$C_6H_4.CO.C_6H_4.NC$ . [119°]. From *p*-amido-benzophenone, chloroform, and alcoholic KOH (Dæbner, *B.* 14, 1338). Silky needles, when hot it smells unpleasant. HCl splits it up into formic acid and amido-acetophenone.

#### *Di-p*-cyano-benzophenone

$C_6H_4(CN).CO.C_6H_4(CN)$ . [205°]. Formed by dry distillation of calcium *p*-cyano-benzoate. Warty crystals. Sublimable. V. sol. alcohol, ether, and benzene, slightly sol. petroleum-ether and hot water. With phenyl-hydrazine it yields the com-

$C_6H_4 \begin{array}{c} \diagup C(NH_2).N_2.HPh \\ \diagdown C:N.HPh \end{array}$ . The latter body

forms warty crystals [212°]; v. sol. alcohol, ether, benzene, and  $CS_2$  (Brönne, *B.* 20, 521).

**Isocyano-benzophenone** v. **BENZOYL-PHENYL-CARBAMINE**.

#### CYANO-BENZOYL-ACETIC ACID.

**Methyl ether**  $CBzHCy.CO.Me$ . [74°]. From methyl cyano-acetate and  $BzCl$  (Barthe, *C. R.* 106, 1416). Long prisms, sol. ether and alcohol. Gives a red colour with  $FeCl_3$ . Its alcoholic solution has an acid reaction. Boiling water splits it up into  $CO_2$  and  $Ph.CO.CH_2.Cy$  [82°]. Its sodium derivative  $Cy.CBzNa.CO_2.Me$  forms hard crystals, decomposing at 123°. Its barium salt  $Ba(CBzCy.CO_2.Me)_2$  aq is also crystalline.

#### **Ethyl ether** $C_6H_5.NO_2$ , i.e.

$C_6H_5.CO.CH(CN).CO_2Et$ . [41°]. From benzoylethyl ether,  $NaOEt$ , and  $CyCl$ . Also from  $CN.CHNa.CO_2Et$  and  $BzCl$  (Haller, *C. R.* 101, 1270; 105, 130). Prisms; sol. alcohol, aqueous alkalis, and  $Na_2CO_3$  aq. Gives an intense red colouration with  $FeCl_3$ . Boiling water forms cyano-acetophenone and  $CO_2$ . Alcoholic HCl gives  $CO_2$  and acetic and benzoic ethers.

#### ***o*-CYANO-BENZYL-AMINE**

$C_6H_4(CN).CH_2.NH_2$ . Formed, together with phthalic acid, by digesting phthal-*o*-cyano-

benzyl-imide with fuming HCl. The solution of its hydrochloride is converted by nitrous acid into nitroso-phthalimidine.— $B'$  HCl aq: glistening needles. Picrate  $B/C_6H_4(NO_2)_2.OH$ : sparingly soluble yellow crystalline pp. (Gabriel, *B.* 20, 2232).

#### ***o*-CYANO-BENZYL CHLORIDE**

$C_6H_4(CN).CH_2.Cl$  [1:2]. [61°]. (252° at 758 mm.). Monosymmetrical colourless crystals  $a:b:c = .7775:1:2939$ ,  $\beta = 60^\circ 2'$ . Prepared by leading chlorine into nearly boiling *o*-cyano-toluene till its weight has increased by 30 p.c. (Gabriel a. Otto, *B.* 20, 2222).

#### ***o*-CYANO-BENZYL-CYANIDE**

$C_6H_4(CN).CH_2.CN$  [1:2]. *o*-Cyano-phenyl-acetonitrile. [81°].

**Preparation.**—*o*-Cyano-benzyl chloride (30 pts.) is added to a solution of 15 pts. of potassium cyanide (96–98 p.c. KCN) in 60 c.c. of water and 300 c.c. of alcohol. After cohobating for ½ hour, ¼ of the alcohol is distilled off and the residue poured into water (about ½ litre); the crystals which separate are recrystallised from alcohol (yield: 25 pts.) (Gabriel a. Otto, *B.* 20, 2224, 2502).

**Properties.**—Colourless plates. V. sol. ordinary solvents. By warming with alcoholic sodium ethylate and  $MeI$  or  $EtI$  it is converted into  $C_6H_4(CN).CHMe.CN$  or  $C_6H_4(CN).CHEt.CN$ . By heating with conc.  $H_2SO_4$  at 80°, and pouring the product into water it is converted into the imide of phenyl-acetic-*o*-carboxylic acid

#### ***o*-CYANO-BENZYLIDENE-PHTHALIDE**

$C_6H_4 \begin{array}{c} \diagup O \\ \diagdown CO \end{array}$  [165°]. Fine yellowish needles.

Formed by heating phthalic anhydride with benzyl cyanide, best with addition of dry sodium acetate (Gabriel, *B.* 18, 1264).

#### ***o*-CYANO-BENZYL-PHTHALIMIDE**

$C_{10}H_8N_2O_2$  i.e.  $C_6H_4 \begin{array}{c} \diagup O \\ \diagdown CO \end{array}$ . **Phthal-*o*-cyano-**

**benzyl-imide**. [182°]. Prepared by heating phthalimide-potassium (9 pts.) with *o*-cyano-benzyl chloride (7 pts.) slowly from 100° to 120°. Large prisms. By boiling with fuming HCl it is split up into phthalic acid and *o*-cyano-benzylamine (Gabriel, *B.* 20, 2231).

***exo*-CYANO-BENZYL-UREA** v. **PHENYL-URAMIDO-ACETONITRILE**.

**CYANO-BORNEOL**. Has been shown by Haller to be bornyl carbamate (*q. v.*). V. also **CINEOL**.

***p*-CYANO-ISOBUTYL-BENZENE** v. **Nitrile of *p*-(iso)-BUTYL-BENZOIC ACID.**

#### ***a*-CYANO-BUTYRIC ACID**

$CH_3.CH_2.CH(CN).CO_2H$ .

***Ethyl ether*  $EtA'$** . (209° cor.). S.G. 2 1-009. From  $\alpha$ -bromo-butyric ether, alcohol, and  $HgCy_2.K_2Cy_2$  at 180° (Markownikoff, *A.* 182, 380). Also from sodium cyano-acetic ether and  $EtI$  (Henry, *C. R.* 104, 1618).

***Amide*  $CH_3.CH_2.CH(CN).CONH_2$** . [113°]. Pearly scales (from alcohol).

## CYANO-BUTYRO-ACETIC ETHER

$\text{CH}_3\text{Me}.\text{CH}_2.\text{CO}.\text{CH}(\text{CN})\text{CO}_2\text{Et}$ . (c.  $172^\circ$ ) under 56 mm. From sodium cyano-acetic ether and butyryl chloride (Haller, C. R. 106, 1083).— $\text{CaA}'$ , 2aq.— $\text{BaA}'$ , 3aq.

## Cyano-iso-butyro-acetic ether

$\text{CHMe}.\text{CO}.\text{CH}(\text{CN})\text{CO}_2\text{Et}$ . ( $174^\circ$ ) at 85 mm. Formed as above from isobutyryl chloride (H.).— $\text{CaA}'$ , 2aq.

## CYANO-CAMPHOR v. CAMPHOR.

CYANO-CARBIMIDAMIDO-BENZOIC ACID v. vol. i. p. 157.

CYANO-CARBONIC ACID v. CYANOFORMIC ACID.

CYANO-CARBOXAMIDO-BENZOIC ACID v. vol. i. p. 157.

## CYANO-TRI-CARBALLYLIC ETHER

$\text{C}_3\text{H}_3\text{NO}_3$ , i.e.  $\text{C}(\text{CN})(\text{CO}_2\text{Et})(\text{CH}_2\text{CO}_2\text{Et})_2$ . ( $141^\circ$ ). (187°). Formed in small quantities in the preparation of cyano-succinic ether (q. v.). It is also formed from cyano-succinic ether by Na and chloro-acetic ether. Colourless. Sol. alcohol and ether; insol. water and alkalis (Haller a. Barthe, C. R. 106, 1414).

$\alpha$ -CYANO-CINNAMYLOUREA v. Nitrile of PHENYL- $\alpha$ -URAMIDO-CROTONIC ACID.

CYANO-CROTONIC ACID  $\text{C}_3\text{H}_3(\text{CN})\text{O}_2\text{H}$ . When liberated from its salts by an acid, it changes to acid ammoniac crotonate.

Salt.— $\text{KA}'$ . From  $\alpha$ -chloro-crotonic acid, cold dilute alcohol and  $\text{KC}_y$  (Claus a. v. Wasowicz, A. 191, 69). Boiled with  $\text{KOH}$  it forms crotonic acid (q. v.).— $\text{AgA}'$ .

$\beta$ -Cyano-crotonic ether  $\text{CH}_3\text{C}(\text{CN})\text{CH}(\text{CO}_2\text{Et})_2$ . (71°). From aceto-acetic ether, formamidine hydrochloride, and dilute aqueous  $\text{Na}_2\text{CO}_3$  (Pinner, B. 18, 2846). Needles (from ether).

## CYANO-ETHYL-ACETO-ACETIC ETHER

$\text{CH}_3\text{CO}_2\text{C}(\text{CN})(\text{Et})\text{CO}_2\text{Et}$ . (108°) at 18 mm. S.G.  $d_4^{20}$  0.976. From sodium aceto-acetic ether and  $\text{CyCl}$ , followed by water (Held, C. R. 98, 522). Oil; insol. aqueous alkalis. Boiling aqueous  $\text{KOH}$  gives acetic and butyric acids,  $\text{NH}_3$ , and  $\text{CO}_2$ .

CYANOFORM  $\text{CHC}_y$ . From chloroform and alcoholic  $\text{KC}_y$  at  $130^\circ$  (Fairley, C. J. 11, 362; Pfankuch, J. pr. [2] 4, 38; 6, 97. According to Claus, A. 191, 35, cyanoforn does not exist). Small needles. Decomposed by  $\text{HCl}$  into  $\text{NH}_3$  and methane tricarboxylic acid  $\text{CH}(\text{CO}_2\text{H})_3$ .

## Compound.—With mercuric iodide.

$3\text{HgI}_2(\text{CHC}_y)_2$ , crystalline needles got by heating iodoform with alcoholic  $\text{HgC}_y$ , at  $120^\circ$ .

CYANO-FORMIC ACID  $\text{CN}.\text{CO}_2\text{H}$ . Cyano-carbonic acid. Semi-nitrile of oxalic acid.

Methyl ether  $\text{CN}.\text{CO}_2\text{Me}$ . (101°). From methyl oxamate  $\text{NH}_2.\text{CO}.\text{CO}_2\text{Me}$  and  $\text{P}_2\text{O}_5$  (Weddige, J. pr. [2] 6, 117; 10, 193). Pungent oil. Quickly decomposed by water into  $\text{HC}_y$ , methyl alcohol, and  $\text{CO}_2$ . Combines with  $\text{H}_2\text{S}$ , forming  $\text{NH}_4.\text{CS}.\text{CO}_2\text{Me}$ .

Ethyl ether  $\text{CN}.\text{CO}_2\text{Et}$ . (116°). Formed by distilling oxamic ether with  $\text{P}_2\text{O}_5$ . Formed also by distilling  $\text{NH}_2.\text{CCl}_2.\text{CO}_2\text{Et}$ , the product of the action of  $\text{PCl}_5$  on oxamic ether (Wallach, A. 184, 12; B. 8, 299). Oil, lighter than water. Slowly decomposed by cold water into  $\text{CO}_2$ , alcohol, and  $\text{HC}_y$ . Conc.  $\text{HCl}$  gives oxalic acid. Ammonia forms  $\text{NH}_4\text{C}_y$  and carbamic ether; alkylamines act similarly.  $\text{HI}$  reduces it to amido-acetic ether.

Isobutyl ether  $\text{CN}.\text{CO}_2\text{CH}_2\text{Pr}$ . (146°).

Allyl ether  $\text{CN}.\text{CO}_2\text{C}_3\text{H}_5$ . (135°). From di-cyano-propyl alcohol (dicyanide of allyl alcohol) and fuming  $\text{HCl}$  (Wagner a. Tollens, B. 6, 1045).

Amide  $\text{CN}.\text{CONH}_2$ . ( $60^\circ$ ). Formed, together with oxamide, by passing cyanogen into 96 p.c. acetic acid and, after a few hours, heating to  $100^\circ$  (Beketoff, J. R. 7, 99). Tables, v. sol. water, alcohol, and ether. Split up at  $120^\circ$  into  $\text{HC}_y$  and cyanuric acid.

Di-ethyl amide  $\text{CN}.\text{CO}.\text{NEt}_2$ . (220°). From  $u$ -di-ethyl-oxamide and  $\text{P}_2\text{O}_5$  (Wallach, B. 14, 737). Oil; volatile with steam; sl. sol. water. Lighter than water.  $\text{PCl}_5$  gives chloroxalethylene.

Para-cyano-formic acid  $(\text{CN}.\text{CO}_2\text{H})_n$ . From its ethers by treatment with cold aqueous  $\text{KOH}$ ; the acid is then ppd. by  $\text{HCl}$  as a bulky mass, insol. alcohol and ether, v. sl. sol. water. Boiling water converts it into oxalic acid and  $\text{NH}_3$ .

Salts.— $\text{K}(\text{C}_y.\text{NO}_2)$ : long needles (from water).— $\text{Ag}(\text{C}_y.\text{NO}_2)$ : yellow pp., insol.  $\text{HNO}_3$ .

Methyl ether  $\text{Me}(\text{COCN})_n$ . ( $154^\circ$ ). Obtained by polymerisation from methyl cyanofornate under the influence of  $\text{HCl}$ . Also from the silver salt and  $\text{MeI}$ . Small needles.

Ethyl ether  $\text{Et}(\text{COCN})_n$ . ( $165^\circ$ ). Formed by saturating cyano-formic ether with  $\text{HCl}$  and heating the liquid to  $100^\circ$  for several hours, or leaving it to itself in the cold for a few weeks (Weddige). Six-sided prisms, v. sl. sol. cold, sl. sol. hot, alcohol. Cannot be distilled. Boiling alkalis give oxalic acid,  $\text{NH}_3$ , and alcohol.

Isobutyl ether  $(\text{Pr}.\text{C}_y)(\text{COCN})_n$ . ( $158^\circ$ ). Amide  $(\text{CN}.\text{CO}.\text{NH}_2)_n$ . Amorphous.

Methylamide  $(\text{CN}.\text{CO}.\text{NHEt})_n$ . ( $250^\circ$ ). Needles.

Anilide  $(\text{CN}.\text{CO}.\text{NHPh})_n$ . Needles.

CYANOGEN  $\text{CN}$ . Mol. formula  $\text{C}_2\text{N}_2$ . Mol. w. 52.96. [ $-34.4^\circ$ ] (Faraday, A. 56, 158; Loit a. Drion, J. 1860, 41). (c.  $-20^\circ$ ) (Bursen, P. 46, 101). S.G.  $d_4^{20}$  0.866 at  $17^\circ$  (Faraday). V.D. 1.805. S. (gas) at  $20^\circ = 4\frac{1}{2}$ ; S. (gas) in alcohol at  $20^\circ = 23$ ; S. (gas) in ether at  $20^\circ = 5$ . Vapour-pressure in atmos. at  $-17.7^\circ = 1.25$ , at  $-9.4^\circ = 1.72$ , at  $-5^\circ = 2$ , at  $0^\circ = 2.37$ , at  $+6.9^\circ = 3$ , at  $17.2^\circ = 4$ , at  $25^\circ = 5$ , at  $31.3^\circ = 6$ , at  $37.4^\circ = 7$  (Faraday, Lc.).  $\mu_0 = 1.000804$ ,  $\mu_\infty = 1.000834$ ,  $\mu_0 = 1.000895$  (Croullebois, A. Ch. [4] 20, 185; v. also Chappuis a. Riviere, C. R. 103, 37). H.F. [ $\text{C}_2\text{N}_2$ ] =  $-65,700$ ; H.C. [ $\text{C}_2\text{N}_2.\text{O}$ ] = 259,820 (Th. 2, 388). For spectrum v. Wüllner (P. 144, 617), and Ciamician (W. A. B. 79 [2nd part], 8); dispersion v. Croullebois (A. Ch. [4] 20, 185), and Mascart (C. R. 71, 617, 679). For transpiration-coefficient v. Meyer (P. 143, 14).

Cyanogen was first prepared by Gay-Lussac in 1815; he compared cyanogen with chlorine, and the compounds of one with those of the other, hence arose the conception of the compound radicle  $\text{CN}$  replacing the simple radicle  $\text{Cl}$ . The name cyanogen (from  $\kappa\alpha\nu\alpha\varsigma$ ) was suggested by the colour of Prussian blue, which was the earliest known compound of cyanogen.

The formula  $\text{C}_y$  is often used to denote cyanogen.

Occurrence.—In the gas from coke-ovens (Bunsen a. Playfair, J. pr. 42, 145).

Formation.—1. By passing induction-sparks between carbon poles in an atmosphere of N

(Morren, *C. R.* 48, 342).—2. By heating  $(\text{NH}_4)_2\text{C}_2\text{O}_4$  or  $\text{C}_2\text{O}_4(\text{NH}_4)_2$ , either alone or with dehydrating agents (Dumas, *A.* 10, 295; Bertagnini, *A.* 104, 176).—3. By heating  $\text{AgCN}$  (Delbrück, *A.* 64, 296) or  $\text{Au}(\text{CN})_3$  (Himly, *A.* 42, 157, 337).

**Preparation.**—Perfectly dry mercuric cyanide is heated in a dry flask or small retort with a long exit tube dipping under mercury in an inverted tube; the cyanide is decomposed to cyanogen and mercury, which condenses in the exit tube.

**Properties.**—A colourless gas, with penetrating odour resembling that of  $\text{HCN}$ . Very poisonous. Burns with purple flame. Liquefied by cold and pressure; at  $-20.7^\circ$  at ordinary pressure; liquefaction may be effected by heating  $\text{Hg}(\text{CN})_2$  or porous charcoal saturated with cyanogen (Melsens, *C. R.* 77, 781) in a Faraday-tube (cf. also Hofmann, *B.* 3, 663). At very low temperatures freezes to a crystalline, ice-like mass. Liquid cyanogen is a colourless, mobile liquid; non-conductor of electricity; dissolves P, I, camphor, and various other bodies (v. Gore, *C. N.* 24, 303). Cyanogen gas is absorbed by  $\text{Hg}$  at  $c. 100^\circ$  (Amagat, *C. R.* 68, 1170); it is also largely absorbed by porous charcoal (Hunter, *C. J.* [2] 9, 76; 10, 642). Cyanogen combines with several non-metals, e.g. with Cl, Br, I, S, P; it also forms compounds with most of the metals; in its chemical relations it shows analogies with the halogens, e.g. in the composition and properties of the acids  $\text{HM}$  and  $\text{HMO}$ , where  $\text{M} = \text{Cl}, \text{Br}, \text{or } \text{CN}$ , and in the composition of many cyanides. The hydracid  $\text{HCN}$  is much weaker than the corresponding halogen acids. Substitution of H in aromatic hydrocarbons by the group  $\text{CN}$  generally results in the production of compounds one or more H atoms in which are acidic (v. Meyer, *B.* 20, 2944; Schneidewind, *B.* 21, 1323; Pöppe, *B.* 21, 1331; Knoevenagel, *B.* 21, 1344). The modes of preparation of cyanogen, e.g. from  $(\text{NH}_4)_2\text{C}_2\text{O}_4$ , and its reaction with  $\text{H}_2\text{O}$  to form  $\text{C}_2\text{O}_4(\text{NH}_4)_2$ , show that it is the nitrile of oxalic acid.

**Reactions.**—1. Heated to  $c. 500^\circ$  paracyanogen is slowly formed (Troost a. Hautefeuille, *C. R.* 66, 735, 795; v. also PARACYANOGEN), at  $c. 1200^\circ$  N is liberated (Meyer a. Goldschmidt, *B.* 16, 1161). Heated in presence of iron or platinum C and N are formed.—2. Decomposed to C and N by a series of electric sparks, but after a time re-formation of Cy begins (Buff a. Hofmann, *A.* 113, 129; Andrews a. Tait, *Pr.* 10, 427).—3. Water dissolves Cy, the solution slowly decomposes, except an acid be present (Gianelli, *J.* 1856, 435), with separation of brown flocks of azulmic acid (Pelouze a. Richardson, *A.* 26, 63), and formation of  $\text{NH}_4$ , oxalate, and carbonate (Vauquelin, *A. Ch.* 9, 113; 22, 132), and also  $\text{HCN}$  and  $\text{CO}_2\text{NH}_2$  (Wöhler, *P.* 16, 627).—4. Alcoholic and ethereal solutions decompose similarly to aqueous solutions (Buff a. Hofmann, *A.* 113, 129; Marchand, *J. pr.* 18, 104).—5. Water in presence of aldehyde produces oxamide.—6. With sulphuretted hydrogen either cyan-thioformamide ( $\text{CN}.\text{CS}.\text{NH}_2$ ) (q. v.) or dithio-oxamide ( $\text{NH}_4.\text{CS}.\text{CS}.\text{NH}_2$ ) (q. v.) is formed, according as the Cy or the  $\text{H}_2\text{S}$  is in excess.—7. Chlorine reacts only in presence of moisture and sunlight,  $\text{CNCl}$  and  $(\text{CN})_2\text{Cl}_2$  are formed (Serullas, *A. Ch.*

[2] 35, 291, 337).—8. Hydrogen at  $500^\circ$ – $550^\circ$  forms  $\text{HCN}$  (Berthelot, *Bl.* [2] 33, 2);  $\text{HCN}$  is also produced when electric sparks are passed through a mixture of Cy and H (Boillot, *C. R.* 76, 1132). Nascent hydrogen (Zn and  $\text{HClAq}$ ) produces ethylene-diamine (q. v.) (Fairley, *A. Suppl.* 3, 371).—9. Potassium and sodium heated in Cy form cyanides.—10. Strongly heated iron decomposes Cy with formation of C and N.—11. Zinc forms cyanide, rapidly at  $100^\circ$ ; cadmium, copper, and lead, at high temperatures, form small quantities of cyanides; mercury and silver do not react (Berthelot, *Bl.* [2] 33, 2).—12. When a mixture of Cy and oxygen is submitted to a powerful electric spark, explosion occurs with production of  $\text{CO}$  and  $\text{CO}_2$ ; with a weak spark no explosion occurs; the explosion is not dependent on the dryness of the gases; slow combustion occurs in presence of strongly heated Pt (Dixon, *C. J.* 49, 384).—13. Conc. cold hydrochloric acid produces oxamide (Schmidt a. Glutz, *B.* 1, 66);  $\text{HCl}$  in absolute alcohol forms oxalic ether (Volhard, *A.* 158, 118; Pinner a. Klein, *B.* 11, 1481).—14. Conc. hydriodic acid when cold forms oxamide (Schmidt a. Glutz, *B.* 1, 66); when hot forms glycooll (Emmerling, *B.* 6, 1352); at  $280^\circ$  forms  $\text{NH}_4$ , and  $\text{C}_2\text{H}_4$  (Berthelot, *J.* 1867, 347).—15. With potash, cyanide and cyanate are formed.—16. With dry ammonia, hydrazulmin,  $\text{C}_2\text{H}_4\text{N}_2$  (q. v. vol. i. p. 429), is formed; when Cy is passed into very conc.  $\text{NH}_4\text{Aq}$ , azulmic acid,  $\text{C}_2\text{H}_4\text{N}_2\text{O}$  (q. v. vol. i. p. 429), is produced; with dilute  $\text{NH}_4\text{Aq}$  oxamide is formed along with  $\text{NH}_4$ , oxalate, and oxamate.

**Combinations.**—1. With hydrogen to form  $\text{HCN}$  (v. Reactions, No. 8).—2. With water in presence of aldehyde to form oxamide.—3. With sulphuretted hydrogen to form cyan-thioformamide or dithio-oxamide (v. Reactions, No. 6).—4. With ammonia to form hydrazulmin, &c. (v. Reactions, No. 16).—5. With some metals to form cyanides (v. Reactions, Nos. 9, 10, 11).

**POLYMERIDE OF CYANOGEN.** Paracyanogen  $\alpha\text{CN}$ . When  $\text{HgCy}_2$  or  $\text{AgCy}$  is heated, a part is changed to a loose, brownish-black solid, having the composition  $\alpha\text{CN}$ ; the value of  $\alpha$  is unknown; Maumené thinks it may be 4 (*Bl.* 35, 597). Liquid cyanogen is slowly polymerised by heating (at  $350^\circ$ – $500^\circ$ , Troost a. Hautefeuille, *C. R.* 66, 735, 795). Paracyanogen is prepared by heating dry  $\text{HgCy}_2$  to  $440^\circ$  in a closed tube for 24 hours, and then passing cyanogen into the tube at the same temperature to volatilise and remove the  $\text{Hg}$  (T. a. H., *Lc.*). The quantity of paracyanogen formed depends on the temperature and pressure. Heated to  $800^\circ$  in a closed tube, or heated in a stream of  $\text{CO}$ , or N, paracyanogen is changed to cyanogen. At each temperature equilibrium results between the cyanogen and paracyanogen when a definite pressure is attained; T. a. H. give the following data:—

Temp.	Equilibrium-pressure
$502^\circ$	84 mm.
506	56 "
559	123 "
575	129 "
587	157 "
599	275 "
601	318 "
629	368 "
640	1310 "

Heated in H. paracyanogen forms HCN,  $\text{NH}_3$ , and C (Delbrück, *J. pr.* 41, 161). With molten KOH it forms KCN and K<sub>2</sub>CN<sub>2</sub>; boiled with conc. KOH it is slowly dissolved with evolution of  $\text{NH}_3$ ; by prolonged boiling with conc.  $\text{HNO}_3$  it forms a yellow solution.

**Cyanogen bromides.** Two are known, ONBr and  $\alpha\text{CNBr}$ ,  $\alpha$  probably = S. Mol. w. of the polymeride is not known with certainty, analogy with  $\text{C}_2\text{N}_2\text{Cl}_2$  points to formula  $\text{C}_2\text{N}_2\text{Br}_2$ . For preparation, &c., v. CYANOGEN BROMIDE and CYANURIC BROMIDE, under CYANIC ACID, p. 313.

**Cyanogen chlorides.** Two are known, CNCl and  $\text{C}_2\text{N}_2\text{Cl}_2$ , v. under CYANIC ACID, p. 312.

**Cyanogen iodides.** Two are known, CNI and a polymeride which is probably  $(\text{CN})_2\text{I}_2$ ; v. under CYANIC ACID, p. 313.

**Cyanogen phosphide  $(\text{CN})_2\text{P}$ .** (*Phosphorus cyanide*.) Mol. w. not determined. White needles; very easily decomposed in contact with moist air to  $\text{P}$ ,  $\text{H}_3\text{PO}_3$ , and HCN. Melts at  $200^\circ$ – $203^\circ$ , and boils a few degrees higher. Takes fire when slightly heated in air. Sl. sol. ether,  $\text{CS}_2$ , and  $\text{PCl}_5$ . With alcohol forms ethylic phosphite and HCN. Prepared by moistening AgCy with  $\text{PCl}_5$  at a low temperature, closing the tube, and heating to  $130^\circ$ – $140^\circ$  for 6 hours, warming (after opening the tube) to remove excess of  $\text{PCl}_5$ , and heating residue to  $130^\circ$ – $140^\circ$  in a stream of dry  $\text{CO}$ , till the  $\text{P}(\text{CN})_3$  sublimes (Hübner a. Wehrhane, *A.* 127, 254; 132, 277).

**Cyanogen selenide  $(\text{CN})_2\text{Se}$**  (Schneider, *P.* 129, 634). Colourless plates; obtained in small quantity by adding dry AgCy to a solution of  $\text{Se}_2\text{Br}_2$  in  $\text{CS}_2$ , and crystallising from  $\text{CS}_2$ . Decomposed by hot water to  $\text{Se}$ ,  $\text{H}_2\text{SeO}_3$ , and HCN.

**Cyanogen sulphides  $(\text{CN})_2\text{S}$ , and  $(\text{CN})_2\text{S}_2$ .** Mol. w. of neither has been determined.

**I. CYANOGEN SULPHIDE.** (*Sulphur cyanide. Sulphocyanic anhydride.*)  $(\text{CN})_2\text{S}$ . Produced by reaction between SI and AgCy,  $\text{SCL}_2$ , and  $\text{HgCy}_2$ , and CyI and Ag<sub>2</sub>S. Prepared by mixing ethereal solution of CyI with an equivalent quantity of AgNCS, evaporating with constant stirring, and allowing to stand in a small closed vessel; the residue is treated with boiling  $\text{CS}_2$ , which dissolves the  $\text{Cy}_2\text{S}$ , leaving AgI; the liquid is cooled to  $0^\circ$ , and the crystals are dried *in vacuo* over  $\text{H}_2\text{SO}_4$ . Forms rhombic plates melting at  $c. 60^\circ$ ; decomposed by heating in moist air; sol. ether, alcohol, and water; decomposed by  $\text{H}_2\text{SO}_4$ ,  $\text{HClAq}$ , or  $\text{HNO}_3$ ; with  $\text{NH}_3$  forms  $\text{NH}_4\text{CyS}$ ; with  $\text{H}_2\text{S}$  forms HCN, HCNS, and S (Linnemann, *A.* 120, 36).

**II. CYANOGEN PERSULPHIDE  $(\text{CN})_2\text{S}_2$ .** Obtained along with  $(\text{CN})_2\text{S}$  in reaction between AgCy and  $\text{SCL}_2$ . Exists in two forms; (1) colourless crystalline mass, sol.  $\text{CS}_2$ ; (2) dark-yellow powder, formed by spontaneous change of (1), insol. alcohol, ether, water, or  $\text{CS}_2$ , becomes electrical when rubbed (Schneider, *J. pr.* [2] 32, 187).

**III. The compound  $\text{C}_2\text{N}_2\text{H}_2\text{S}$** , is sometimes called PSEUDOCYANOGEN SULPHIDE. This body is produced by the action of oxidisers on HSCN or on soluble sulphocyanides. Obtained by passing Cl into KSCNAq, or gently warming a solution of 1 pt. KSCN in 3 pts. water with  $\frac{1}{4}$  its weight of conc.  $\text{HNO}_3$ ; the yellow pp. is repeatedly washed with hot water ( $\text{H}_2\text{C}_2\text{N}_2\text{S}_2$  is dissolved out, Jamieson, *A.* 59, 389), then with  $\text{CS}_2$  (which

removes S, Linnemann, *A.* 120, 36), it is then dissolved in conc.  $\text{H}_2\text{SO}_4$ , re-ppd. by water, dried, boiled with absolute alcohol and again dried (Vöckel, *A.* 89, 126; Letnii, *D.* 8, 767; Laurent a. Gerhardt, *A. Ch.* [3] 19, 98; Liebig, *P.* 15, 546; Wöhler, *G.* 4, 69, 271). Insol. in water, alcohol, and ether; sol. without change in conc.  $\text{H}_2\text{SO}_4$ , and in dilute alkalis; sl. sol. in  $\text{NH}_4\text{Aq}$ . Decomposed by molten KOH to KSCy and  $\text{KC}_2\text{O}$ ; heated with conc.  $\text{NH}_4\text{Aq}$  to  $100^\circ$   $\text{NH}_4\text{SCy}$  and  $\text{C}_2\text{H}_3\text{N}_2\text{S}$  (thio-ammelin) are formed. Heated with  $\text{PCl}_5$  reacts thus  $\text{C}_2\text{N}_2\text{H}_2\text{S} + 3\text{PCl}_5 = \text{C}_2\text{N}_2\text{Cl}_2 + 2\text{PCl}_3 + \text{PSCl}_2 + \text{S}_2\text{Cl}_2 + \text{HCl}$  (Ponomareff, *C. R.* 79, 1335). Heated alone, gives  $\text{CS}_2$ , S, and mellone ( $\text{C}_6\text{N}_2\text{H}_4$ ) (Liebig, *P.* 15, 546). Heated with Cl, forms  $\text{CyCl}$ ,  $\text{S}_2\text{Cl}_2$ , and mellone. Conc.  $\text{HClAq}$  at  $130^\circ$ – $140^\circ$  produces  $\text{CS}_2$ , S, and cyanuric acid. Not acted on by nascent H, nor by  $\text{HIAq}$  (Glutz, *A.* 154, 39, 44, 48).

M. M. P. M.

**CYANOGEN HYDROXIDE v. CYANIC ACID.**

**CYANO-MALONIC ETHER  $\text{CN}.\text{CH}(\text{CO}_2\text{Et})_2$ .**

Formed by acting on sodium malonate with cyanogen chloride. Formed also from sodium cyano-acetic ether and  $\text{ClCO}_2\text{Et}$  (Haller, *B.* [2] 39, 262; *C. R.* 95, 143; 105, 169). Strong acid, forming crystalline lead and calcium salts. Boiling alkalis give malonic acid.

Salts.— $\text{NaCCy}(\text{CO}_2\text{Et})_2$ ; slender needles.— $\text{CaA} \cdot 2\text{aq}$ ; triclinic prisms.— $\text{PbA}$ , aq.  $[88^\circ]$ . Needles.

**CYANO-MELAMIDINE v. GUANIDINE.**

**CYANO-METHYL-ACETO-ACETIC ETHER**

$\text{CH}_3.\text{CO}.\text{CMe}(\text{CN}).\text{CO}_2\text{Et}$ . ( $c. 93^\circ$ ) at 20 mm. S.G.  $^{20} 0.996$ . From methyl-aceto-acetic ether, NaOEt, and  $\text{CyCl}$  (Held, *C. R.* 98, 522; *B.* [2] 41, 330). Oil; insol. alkalis. Boiling alkalis form acetic and butyric acids.

**CYANO-NAPHTHALENE v. Nitrile of NAPHTHOIC ACID.**

**CYANO-NAPHTHOPHENAZINE  $\text{C}_{11}\text{H}_6\text{CyN}_2$**   $[237^\circ]$ . From sodium naphthophenazine sulphate by distilling with KCy and  $\text{K}_2\text{FeCy}_4$  (Brunner a. Witt, *B.* 20, 2660). Alcoholic KOH gives naphthophenazine carboxylic acid [above  $360^\circ$ ].

**$\alpha$ -CYANO-( $\alpha$ )-NAPHTHYL- $\alpha$ -AMIDO-PROPIONIC ACID  $\text{CH}_2\text{C}(\text{CN})(\text{NHC}_6\text{H}_4)\text{CO}_2\text{H}$ .**

*Ethyl ether A'Et.*  $[134^\circ]$ . Formed by digesting  $\alpha$ -cyano- $\alpha$ -oxy-propionic ether with ( $\alpha$ )-naphthylamine. Small white plates; sol. hot water, sparingly cold, v. sol. alcohol and benzene (Gerson, *B.* 19, 2968).

**$\alpha$ -Cyano-( $\beta$ )-naphthyl- $\alpha$ -amido-propionic acid  $\text{CH}_2\text{C}(\text{CN})(\text{NHC}_6\text{H}_4)\text{CO}_2\text{H}$ .**

*Ethyl ether A'Et.* Formed by heating  $\alpha$ -cyano- $\alpha$ -oxy-propionic ether with ( $\beta$ )-naphthylamine. Small rosettes; sol. benzene and hot alcohol, nearly insol. water and cold alcohol (Gerson, *B.* 19, 2969).

**$\alpha$ -CYANO- $\alpha$ -OXY-PROPIONIC ACID**

$\text{CH}_2\text{C}(\text{OH})(\text{CN}).\text{CO}_2\text{H}$ . *Pyruvic-acid-cyanhydrin*. Crystals (containing  $\text{EtOH}$ );  $[151^\circ]$ . Formed by slowly adding pyruvic acid to KCN suspended in boiling alcohol (Gerson, *B.* 19, 2963).

**CYANO-PHENOL v. Nitrile of OXY-BENZOIC ACID.**

**$\alpha$ -CYANO-PHENYL-ACETO-NITRILE v.  $\alpha$ -**

**CYANO-BENZYL CYANIDE.**

**$\beta$ -CYANO-PHENYL- $\beta$ -AMIDO-BUTYRIC ETHER  $\text{CH}_2\text{C}(\text{CN})(\text{NHPh}).\text{CH}_2\text{CO}_2\text{Et}$ .** Formed

by the action of aniline upon the cyanhydrin of acetoacetic ether (Schiller-Wechsler, *B. 18*, 1039).

**$\alpha$ -CYANO- $\alpha$ -PHENYL-AMIDO-PROPIONIC ETHER**  $\text{CH}_2\text{C}(\text{CN})(\text{NHPh})\text{CO}_2\text{Et}$ . [102°]. Formed by digesting an alcoholic solution of  $\alpha$ -cyano- $\alpha$ -oxy-propionic ether with aniline for 24 hrs. at 80°. Large trimetric crystals,  $a:b:c = 7902:10:156366$  (Gerson, *B. 19*, 2963).

**$\alpha$ -CYANO-PHENYL-BUTYRONITRILE**  $\text{C}_6\text{H}_5(\text{CN})\text{CHEt.CN}$ .  *$\alpha$ -Ethyl-homo- $\alpha$ -phthalonitrile*. [40°]. (294°). Formed by warming  $\alpha$ -cyano-benzyl-cyanide  $\text{C}_6\text{H}_5(\text{CN})\text{CH}_2\text{CN}$  with alcoholic  $\text{NaOEt}$  and  $\text{EtI}$ . Short thick prisms. By heating with conc.  $\text{H}_2\text{SO}_4$  and pouring into water it is converted into the imide of phenyl-

ethyl-acetic- $\alpha$ -carboxylic acid  $\text{C}_6\text{H}_5\text{CH}(\text{CO}-\text{NH})\text{CH}_2\text{CO}$  (Gabriel, *B. 20*, 2505).

**DI-CYANO-DI-PHENYL-ETHANE**  $\text{CN.CHPh.CHPh.CN}$ . [218°]. Crystalline solid. *Formation*.—1. By reduction of di-cyano-diphenyl-ethylene with sodium-amalgam.—2. Together with di-cyano-di-phenyl-ethylene by boiling phenyl-bromo-acetonitrile with an excess of alcoholic KCN (Reimer, *B. 14*, 1799).

**DI-CYANO-DI-PHENYL-ETHYLENE**  $\text{CN.CPh:CPh.CN}$ . *Di-cyano-stilbene* [158°]. Colourless plates. Insol. water, sol. hot alcohol, benzene, acetic acid, and  $\text{CS}_2$ . Prepared by the action of bromine on benzyl cyanide, or from phenyl-bromo-acetonitrile by heating to 170° or, better, by boiling with alcoholic KCN (Reimer, *B. 13*, 742; 14, 1798). By boiling with alcoholic KOH it gives diphenyl-fumaric anhydride. By reduction with zinc and HCl it gives a compound of the constitution  $\text{C}_{16}\text{H}_{12}\text{N}_2$  which forms small needles melting at [208°]; insol. water, sol. alcohol.

#### CYANO-PHENYL-METHYL-TRIAZOLE

$\text{C}_{10}\text{H}_8\text{N}_4$ , probably  $\text{N}-\text{NPh}$   
 $\text{MeC}=\text{N}=\text{C}(\text{CN})$  [109°]. Formed by the action of acetic anhydride upon di-cyan-phenyl-hydrazine. Also by warming di-cyan-phenyl-hydrazine with pyruvic acid in alcohol:  $\text{Ph.N}(\text{NH}_2)\text{C}(\text{CN})\text{NH} + \text{CH}_3\text{CO}_2\text{CH} = \text{C}_6\text{H}_5\text{N}_4 + \text{HCO}_2\text{H} + \text{H}_2\text{O}$ . By alcoholic KOH it is converted into phenyl-methyl-triazole-carboxylic acid [170°] (Bladen, *B. 19*, 2598).

**$\alpha$ -CYANO-PHENYL-PROPIO-NITRILE**  $\text{C}_6\text{H}_5(\text{CN})\text{CHMe.CN}$ .  *$\alpha$ -Methyl-homo- $\alpha$ -phthalonitrile*. [37°]. (285°). Large trimetric crystals;  $a:b:c = 9449:1:10800$ ;  $\alpha = 97^\circ 2'$ ,  $\beta = 103^\circ 13'$ ,  $\gamma = 87^\circ 11'$ . Prepared by warming an alcoholic solution of  $\alpha$ -cyano-benzyl-cyanide ( $\alpha$ -cyano-phenyl-aceto-nitrile) with KOH and methyl iodide. V. sol. ordinary solvents, sl. sol. ligroin. By heating with conc.  $\text{H}_2\text{SO}_4$  at c. 130° and pouring into water it yields the imide of phenyl-

methyl-acetic-carboxylic acid  $\text{C}_6\text{H}_5\text{CH}(\text{CO}-\text{NH})\text{CHMe.CO}$  (Gabriel, *B. 20*, 2503).

#### CYANO-PHENYL-TETRAZOLE

$\text{N}=\text{N}-\text{N}=\text{C.N}$   
 $\text{N}=\text{C.N}$ . Formed by the action of nitrous acid upon di-cyano-phenyl-hydrazine. On saponification it gives phenyl-tetrazole-carboxylic acid (Bladin, *B. 18*, 2907).

#### $\alpha$ -CYANO-PROPIONIC ACID

$\text{CH}_2\text{CH}(\text{CN})\text{CO}_2\text{H}$ . *Ethyl ether EtA'*. (191°). V.D. 4.34. From sodium cyano-acetic ether and  $\text{CyCl}$  (Henry, *C. R.* 101, 1618). Heavy oil.

**$\beta$ -Cyano-propionic acid. Amide**  $\text{CN.CH}_2\text{CH}_2\text{CONH}_2$ . Formed, together with ethylene cyanide, by digesting ethylene bromide with alcoholic  $\text{KC}_y$  (Pinner, *B. 16*, 360). Prisms (from water).

**Cyano-propionic acid (?)  $\text{C}_2\text{H}_5\text{NO}_2$** . Prepared by dissolving wool (1 pt.) in water by means of KOH (3 pts.), and oxidising by  $\text{KMnO}_4$  (2 pts.) (Wanklyn a. Cooper, *P. M.* [5] 7, 356). Amorphous, pale yellow, brittle solid (containing 1½ aq). Softens at 100°. V. sol. water and alcohol. When strongly heated it gives off acetonitrile. Potash-fusion gives ethylamine and oxalic acid.

*Salts*.—Sol. water, but not in alcohol.— $\text{KA}'\text{aq}$ .— $\text{KA}'_2\text{aq}$ .— $\text{KA}'_3\text{aq}$ .— $\text{CaA}'_2\text{aq}$  (at 100°).— $\text{BaA}'_2\text{aq}$  (at 100°).— $\text{Ba}_2\text{A}'_2\text{O}7\text{aq}$ .— $\text{PbA}'_2\text{aq}$  (at 100°).— $\text{MgA}'_2\text{aq}$ .— $\text{AgA}'_2\text{aq}$  (at 100°).— $\text{Ag}_2\text{A}'_2(\text{OH})\text{aq}$  (at 100°).

#### CYANO-PROPIONYL-ACETIC ETHER

$\text{CH}_2\text{Me.CO.CHCy.CO}_2\text{Et}$ . (160°) at 50 mm. From sodium cyano-acetic ether and propionyl chloride (Haller, *C. R.* 106, 1083).— $\text{CaA}'_2\text{aq}$ : long needles, v. sol. water.

#### DI-CYANO-PROPYL ALCOHOL

$\text{CH}_2\text{Cy.CHCy.CH}_2\text{OH}$ . (151°). From allyl alcohol and cyanogen (Tollens, *B. 5*, 621).

**CYANO-PYRIDINE** v. *Nitrile of Pyridine* CARBOXYLIC ACID.

**CYANO-QUINOLINE** v. *Nitrile of Quinoline* CARBOXYLIC ACID.

**CYANO-SUCCINIC ETHER**  $\text{C}_4\text{H}_3\text{NO}_2$ , i.e.  $\text{CH}(\text{CN})(\text{CO}_2\text{Et})\text{CH}_2\text{CO}_2\text{Et}$ . (158°) at 14 mm. Formed, together with cyano-tricarballic ether, by the action of sodium on cyanoacetic ether dissolved in alcohol, the product being decomposed with chloro-acetic ether. Oil. Sol. alcohol, ether, and alkalis (Maller a. Barthe, *C. R.* 106, 1413).— $\text{C}_2\text{H}_5\text{NaNO}_2$ .

#### CYANO-TEREPHTHALIC ACID

$\text{C}_8\text{H}_4(\text{CN})(\text{CO}_2\text{H})_2$ . From amide-terephthalic acid by cuprous cyanide and nitrous acid (Ahrens, *B. 19*, 1635). Amorphous yellow mass. Decomposed by boiling alkalis into trimellitic acid.

**$\alpha$ -CYANO- $\alpha$ -TOLUIC ACID**  $\text{C}_7\text{H}_7\text{NO}_2$ , i.e.  $\text{CN.CH}_2\text{C}(\text{H})\text{CO}_2\text{H}$ . (116°). From phthalide and alcoholic  $\text{KC}_y$  (W. Wislicenus, *A.* 233, 102). Crystalline powder (from HOAc). Aqueous KOH gives  $\text{CO}_2\text{H.CH}_2\text{C}(\text{H})\text{CO}_2\text{H}$ .— $\text{CaA}'_2\text{aq}$ .

**$\beta$ -CYANO- $\beta$ - $\alpha$ -TOLYLAMIDO-BUTYRIC ETHER**  $\text{CH}_3\text{C}(\text{CN})(\text{NHCH}_2\text{CH}_2\text{CH}_2\text{CO}_2\text{Et})$ . Formed by heating the cyanhydrin of acetoacetic ether with  $\alpha$ -toluidine (Schiller-Wechsler, *B. 18*, 1050).

**$\alpha$ -CYANO- $\alpha$ - $\alpha$ -TOLYLAMIDO-PROPIONIC ETHER**  $\text{CH}_2\text{C}(\text{CN})(\text{NHCH}_2\text{CH}_2\text{CO}_2\text{Et})$ . [93°]. Formed by digesting  $\alpha$ -cyano- $\alpha$ -oxy-propionic ether with  $\alpha$ -toluidine in alcoholic solution. Small white needles; v. sol. benzene and warm alcohol, sl. sol. cold alcohol, insol. water (Gerson, *B. 19*, 2960).

**$\alpha$ -Cyano- $\alpha$ - $p$ -tolylamido-propionic ether**  $\text{CH}_2\text{C}(\text{CN})(\text{NHCH}_2\text{CH}_2\text{CO}_2\text{Et})$ : [81°]; glistering spangles; sol. alcohol and benzene, sl. sol. water

Formed by digesting  $\alpha$ -cyano- $\alpha$ -oxy-propionic ether in alcoholic solution with *p*-toluidine (Gerson, *B.* 19, 2967).

**$\gamma$ -CYANO-VALERIC ACID**  $C_5H_7O_3$ , i.e.  $C_4H_5CO_2H$ . [95°]. Formed by heating valerolactone to 290° with KCN. Prisms. Sol. water,  $CHCl_3$ , and  $C_2H_5$ . Gives, on saponification,  $\alpha$ -methyl-glutaric acid (W. Wislicenus, *A.* 233, 114).

**CYANPHENINE** v. **CYAPHENINE**.

**CYANPROPINE**  $C_7H_7N_3$ . [115°]. S. 0.63 at 23°. Formed by the action of sodium on butyronitrile under an extra pressure of about 20 cm. of mercury (E. v. Meyer, *J. pr.* [2] 37, 897). White prisms (from ether).

**Reactions**.—1. Is converted by heating with conc. HCl to 180° into  $C_7H_7N_3O$ , [97°], S. 0.67 at 23°.—2. Gives with bromine in an acid solution the hydrobromide of bromocyanpropine from which ammonia liberates the base [80°].

**Salt**.— $(B\cdot HCl)_2PtCl_4$ . [97°]. Reddish-yellow prisms.

**CYANURATES** (metallic); and **SULPHO-CYANURATES** (metallic). Cyanuric acid is a polymeric acid of cyanic acid HNCN; it probably has the constitution  $(CN)_3(OH)_3$ .

**CYANURATES**. Cyanuric acid is tribasic; with most bases, however, it forms acid salts. Cyanurates of the alkalis and alkaline earths are sol. water, the others are insol., or only sl. sol.; the alkali cyanurates are decomposed by heat to HNCN,  $(NH_4)NCO$ ,  $CO_2$ , N, and cyanate of the metal; the cyanurates are decomposed by  $H_2SO_4$  or  $HNO_3$  giving  $H_3N_3C_3O_3$ .

**Ammonium cyanurate**  $(NH_4)_3H_3N_3C_3O_3 \cdot H_2O$ ; white lustrous prisms, which effloresce in air.

**Barium cyanurates**.

(1)  $Ba(H_3N_3C_3O_3)_2 \cdot 2H_2O$ ; obtained by adding  $BaO$  to boiling  $H_3N_3C_3O_3$  till slight permanent pp. is formed; loses  $2H_2O$  at 280°. (2)  $Ba(HN_3C_3O_3)_2 \cdot 3H_2O$ ; crystalline pp. by adding boiling  $H_3N_3C_3O_3$  to ammoniacal  $BaCl_2$  (Wöhler, *A.* 62, 241).

**Calcium cyanurate**. Not obtained in definite form (Chevallier a. Lassaigne, *A. Ch.* [8] 18, 155).

**Copper cyanurates**. The normal salt  $Cu_2(C_3N_3O_3)_2 \cdot H_2O$  is obtained by mixing acid Mg cyanurate with  $CuSO_4$ ; when  $Na_2C_3N_3O_3$  is used the salt  $CuHCN_3C_3O_3 \cdot 3H_2O$  is obtained (Claus a. Putensen, *J. pr.* [2] 38, 208). C. a. P. also obtained the basic salt  $(CuOH)_2C_3N_3O_3 \cdot 3H_2O$ . The following ammonio-copper cyanurates are described:  $Cu(HN_3C_3O_3)_2 \cdot 2NH_3 \cdot H_2O$  (W., *L.c.*);  $Cu(H_3N_3C_3O_3)_2 \cdot 2NH_3$  (Wiedemann, *P.* 73, 73);  $Cu(H_3N_3C_3O_3)_2 \cdot xNH_3$ , where  $x = 3$  and 4, and the acid salt  $Cu(H_3N_3C_3O_3)_2 \cdot H_3N_3C_3O_3 \cdot NH_3 \cdot H_2O$  (C. a. P., *L.c.*).

**Lead cyanurate**  $Pb(HN_3C_3O_3)_2 \cdot 3H_2O$ ; pp. obtained in microscopic prisms by dropping excess of basic Pb acetate into boiling  $H_3N_3C_3O_3$ ; decomposed to  $(NH_4)CN$ ,  $CO(NH_2)_2$ , and Pb by heating in H (W., *L.c.*).

**Potassium cyanurates**. (1)  $KH_3N_3C_3O_3$ ; by adding  $HCl$  to crude K cyanate solution; difficultly sol. water (Liebig a. Wöhler, *P.* 20, 369; Campbell, *A.* 28, 52). (2)  $K_2HN_3C_3O_3$ ; by adding alcohol to solution of the first salt, in presence of KOH; decomposed by water to KOH and the dihydrogen salt (L. a. W., *L.c.*).

**Silver cyanurates**. (1)  $AgHN_3C_3O_3$ ; pp. obtained by adding cyanuric acid to silver acetate in acetic acid (W., *L.c.*). (2)  $Ag_2C_3N_3O_3$ ; by adding hot  $AgNO_3$  to hot  $H_3N_3C_3O_3$  in  $NH_3$  Aq, and drying pp. at 300° (Liebig, *A.* 26, 123; Debus, *A.* 72, 20; cf. Wöhler, *A.* 62, 241).

**Silver-ammonium cyanurates**.

(1)  $AgHN_3C_3O_3 \cdot 2NH_3$ ; formed by digesting the first Ag salt with  $NH_3$  Aq; loses all  $NH_3$  on heating. (2) Another salt is described by Liebig (*A.* 26, 123; cf. Wöhler, *A.* 62, 241), probably  $Ag_2C_3N_3O_3 \cdot (NH_3)_2C_3N_3O_3 \cdot H_2O$ .

**Silver-potassium and silver-lead cyanurates**. By boiling triargentate cyanurate with KOH Aq a salt is formed, probably  $Ag_2K_2C_3N_3O_3$  (W., *L.c.*). By boiling Pb cyanurate with excess of  $AgNO_3$  Aq, the salt  $Ag_2Pb(C_3N_3O_3)_2 \cdot 2H_2O$  is produced (W., *L.c.*).

**Sodium cyanurate**  $Na_2C_3N_3O_3$ ; fine needles; separates on adding excess of hot  $NaOHA$  to conc.  $H_3C_3N_3O_3$  Aq (Hofmann, *B.* 3, 770).

**SULPHOCYANURATES** (Hofmann, *B.* 18, 2196).

**Salts of sulphocyanuric acid**,  $H_2C_3N_3S_3$ . For an account of sulphocyanuric acid v. CYANIC (SULPHO) ACID and POLYMERIDES, p. 303.

**Sodium sulphocyanurate**

$NaH_2C_3N_3S_3$ ; large crystals, e. sol. water; formed by digesting  $Na_2S$  with methyl sulphocyanurate. Sulphocyanurates of Cu, Pb, Li, K, and Ag are described.

**DISULPHOCYANIDES** (Fleischer, *A.* 179, 204). **Salts of disulphocyanic acid**  $H_2S_2C_3N_3$  (q. v. p. 303, under CYANIC (SULPHO) ACID and POLYMERIDES).

**Potassium disulphocyanide**

$K_2S_2C_3N_3 \cdot 11H_2O$ ; obtained by adding an alcoholic solution of KOH to persulphocyanic acid,  $H_2C_3N_3S_3$ , and pressing the crystals which separate. Yellow monoclinic prisms; insol. absolute alcohol; v. sol. water; solution in water changes, quickly when heated, to K sulphocyanide. The other salts described by Fleischer (*L.c.*) are  $BaS_2C_3N_3 \cdot 2H_2O$ ; v. soluble, white rhombic prisms;  $CuS_2C_3N_3$ , brown-red pp. insol. dilute acids;  $PbS_2C_3N_3$ , citron-yellow pp. not acted on by dilute acids;  $AgS_2C_3N_3$ , green pp.;  $AgKS_2C_3N_3$ , yellow, crystalline.

M. M. P. M.

**CYANURIC ACID** v. p. 319.

**CYANURIC BROMIDE** v. p. 320.

**CYANURIC CHLORIDE** v. p. 319.

**CYANURIC ACID**  $C_3H_3N_3O_3$ . An unstable crystalline body formed by dissolving the cyanide of barbituric acid (q. v.) in aqueous KOH (Nencki, *B.* 5, 887).

**CYAPHENINE**  $(C_6H_5N)_2$ , i.e.  $Cy_2Ph_2$ . [230°]. (above 350°).

**Formation**.—1. By heating benzoyl chloride with KNCN (Cloez, *A.* 115, 27).—2. By heating benzonitrile bromide alone or with lime (Engler, *A.* 133, 146).—3. From benzonitrile and Na (Hofmann, *B.* 1, 194).—4. Traces are got from benzamide and  $COCl_2$  (E. Schmidt, *J. pr.* [2] 5, 35). 5. From benzonitrile and  $ZnEt_2$ , the product being treated with alcohol and then with HCl (Frankland a. Evans, *C. J.* 37, 564).—6. From  $Cy_2Cl_2$ , bromo-benzene dissolved in ether, and sodium (Klason, *J. pr.* [2] 35, 82),  $Cy_2ClPh_2$  [180°] being the chief product.

**Preparation**.—10 g. of benzonitrile are added

gradually to 50 g. of slightly fuming  $\text{H}_2\text{SO}_4$ , kept cold. After 48 hours the liquid is slowly poured into 800 cc. water. The ppd. cyaphenine, after washing with water and alcohol, weighs 1.1 g. A. Pinner, *J. pr.* [2] 30, 126; B. 11, 764).

**Properties.**—White branching crystals. Insol. water, v. sl. sol. alcohol and ether. Not affected by boiling KOH or HCl.

**Reactions.**—Heated in a sealed tube at  $250^\circ$  with conc. HCl it is entirely converted into benzoic acid and  $\text{NH}_3$  (F. a. E.).

**CYCLAMIN**  $\text{C}_8\text{H}_{10}\text{O}_2$  (?) [236°].  $[\alpha]_D^{20} = -11^\circ 40'$  (in alcohol) (Michaud, *C. C.* 1887, 1397);  $= -15^\circ 10'$  (Sachse). Occurs in the roots of *Cyclamen europaeum* and perhaps also of cowslips ('*Primulin*') (De Luca, *Cimento nuovo*, 5, 225; 8, 182; *G. Z.* 2, 556; Martius, *Buchner's N. Repert.* 8, 388; Mutschler, *A.* 185, 214; Mückiger, *Ph.* [3] 8, 488). White amorphous substance (from alcohol). Irritates the throat. V. sol. boiling alcohol, insol. ether, chloroform,  $\text{CS}_2$ , and alkalis. Absorbs water from moist air, swelling up; slowly dissolves in water. The aqueous solution froths like soap, and is coagulated by heating. In contact with water it slowly decomposes forming glucose and mannite (De Luca, *C. R.* 87, 297). Aqueous HCl coagulates it and, at  $80^\circ$ , forms sugar.  $\text{HOAc}$  dissolves it and does not coagulate it on heating. It gives a white pp. with Fehling's solution, but does not reduce it even when hot. Conc.  $\text{H}_2\text{SO}_4$  forms a red solution; on diluting with water glucose remains in solution, and there is ppd. white amorphous cyclamiretin  $\text{C}_7\text{H}_8\text{O}_2$  [198°]. Chlorine water forms 'cyclamic acid'  $\text{C}_8\text{H}_8\text{O}_4$  (?)  $\text{HNO}_3$  forms 'chrysolin'  $\text{C}_{10}\text{H}_{10}\text{NO}_4$ .

**CYCLOPIC ACID**  $\text{C}_8\text{H}_8\text{O}_4$ . Occurs in the leaves of *Cyclophylla Vogelii* (Cape Tea). The aqueous decoction is digested with  $\text{Pb}(\text{OH})_2$ , the lead compound suspended in dilute (50 p.c.) alcohol, and decomposed by  $\text{H}_2\text{S}$ . The filtrate is concentrated and mixed with alcohol and ether. Cyclopin is ppd.; cyclopic acid is obtained by evaporating the filtrate (Church, *C. N.* 22, 2; *Ph.* [3] 11, 693; Greenish, *Ph.* [3] 11, 569). Yellow needles, sol. water, insol. alcohol, ether, and  $\text{CS}_2$ . Aqueous alkalis form a yellow solution with green fluorescence.  $\text{FeCl}_3$  gives a green colour, becoming brown on heating. Cupric acetate gives a grey pp.  $\text{K}_2\text{Cr}_2\text{O}_7$  and HCl give a dark brownish-red colour.

**Cyclopin**  $\text{C}_8\text{H}_8\text{O}_3$ , aq. Obtained as above. Red substance, v. sol. water, insol. benzene,  $\text{CS}_2$ , ether,  $\text{CHCl}_3$ , and ligroin. Its aqueous solution decomposes on standing into glucose and cyclopin-red. KOH gives a brownish-red solution with green fluorescence.  $\text{FeCl}_3$  gives an olive-green colour turned yellow by HCl and brown by  $\text{NH}_3$ . Ppts. salts of Cu, Pb, and Ag.

**Cyclopin-red**  $\text{C}_8\text{H}_8\text{O}_4$ . Formed as above. Sl. sol. water, ether, and benzene, v. sol. alcohol (when freshly ppd.). Alkalis dissolve it, forming red solutions.  $\text{FeCl}_3$  gives a brown colour.  $\text{CaCl}_2$  or alum followed by  $\text{NH}_3$  gives a violet pp.

**CYCLOTHRAUSTIC ACID**  $\text{C}_8\text{H}_{12}\text{N}_2\text{O}_4$ , i.e.  $[\text{2-1}] \text{CO}_2\text{H.C}_6\text{H}_4\text{.NH.CO.C}_6\text{H}_4\text{.NH}[\text{Py. 3}]$ . [252°].

**Formation.**—a-Diquinoline is oxidised by  $\text{KMnO}_4$  in presence of hot conc.  $\text{AcOH}$ . The pp. is filtered and digested with  $\text{SO}_2$  until all the  $\text{MnO}_2$  is converted into sulphate. After filtering again and well washing with hot water, the acid

is dissolved in KOH. The K-salt is decomposed with weak  $\text{H}_2\text{SO}_4$ , washed, dried, recrystallised from boiling xylene, and decolourised with animal charcoal.

**Preparation.**—By heating dry anthranilic and quinaldinic acids together to  $180^\circ$  (Weidel a. Wilhelm, *M.* 8, 197).

**Properties.**—White woolly needles; insol. water, v. sl. sol. hot  $\text{EtOH}$ ,  $\text{Et}_2\text{O}$ ,  $\text{CHCl}_3$ ,  $\text{C}_6\text{H}_6$ , and xylene; v. sol. hot  $\text{AcOH}$  and HCl.

**Salts.**— $\text{A}'_2\text{Ca}$  aq: yellow flakes.— $\text{A}'_2\text{Ba}$  aq.

**Reactions.**—1. With  $\text{Ac}_2\text{O}$  it forms an anhydride  $\text{C}_8\text{H}_8\text{N}_2\text{O}_2$  [196°], crystallising in long colourless needles.—2.  $\text{KMnO}_4$  in alkaline solution oxidises it to 'pyridanthrilic acid'  $\text{C}_8\text{H}_8\text{N}_2\text{O}_4$ , in acetic acid solution quinaldinic,  $\alpha$ -oxysuccinichromic, and anthranilic acids are formed (Weidel a. Strache, *M.* 7, 285).

**CYMENE**  $\text{C}_{10}\text{H}_{16}$ , i.e.  $\text{C}_6\text{H}_5\text{MePr}[14]$ . *p*-Propyl-toluene. Mol. w. 134. (175°). V.D. 4.63 (calc. 4.65). S.G.  $^{25}_4$  0.864 (Schiff, *A.* 220, 94);  $^{20}_4$  0.8509 (Bruhl, *A.* 235, 19). C.E. (9.8 to  $17.5^\circ$ ) 0.01159 (S.).  $\mu_s$  1.494 (B.).  $\mu_D$  1.484 (Gladstone, *C. J.* 49, 623). H.C. 1401609 ( $\text{C}$ ,  $\text{O}_2=94$ ;  $\text{H}$ ,  $\text{O}=69$ ) (Stohmann, *J. pr.* [2] 35, 41). S.V. 184.5 (Schiff); 181.62 (Ramsay).

**Occurrence.**—In the volatile oil of cumin (from *Cuminum Cuminum*); in the seeds of the water-hemlock (*Cicuta virosa*); in the oil of thyme; in oil of *Ptychotis Ajowan*; in Eucalyptus oil; and to the extent of 6 p.c. in oil of lemons (Gerhardt a. Cahours, *A. Ch.* [3] 1, 102, 372; *A.* 38, 101, 345; Trapp, *A.* 108, 386; Lallemand, *A. Ch.* [3] 40, 156; Haines, *C. J.* 8, 289; H. Müller, *B.* 2, 130; Faust a. Homeyer, *B.* 7, 1429; *Ar. Ph.* [3] 5, 385; Beilstein a. Kupfer, *B.* 6, 1181; *A.* 170, 282; Fittica, *A.* 172, 303; Tilden, *Ph.* [3] 9, 654).

**Formation.**—1. By the dehydration of camphor by means of  $\text{P}_2\text{O}_5$ ,  $\text{ZnCl}_2$ ,  $\text{P}_2\text{S}_5$ , or  $\text{PCl}_5$  (Gerhardt, *A.* 48, 234; Delalande, *A.* 38, 342; Pott, *B.* 2, 121; Fittig, Köbrich, *A.* Jilke, *A.* 115, 129; Wright, *C. J.* 26, 686; Beckett a. Wright, *C. J.* 29, 1).—2. By heating dibromides of terpenes  $\text{C}_{10}\text{H}_{16}\text{Br}_2$  with aniline (Oppenheim, *B.* 5, 94, 628).—3. By distilling crystallised terpin hydrate with Br (Barbier, *C. R.* 74, 194). 4. From thymol and  $\text{P}_2\text{S}_5$ .—5. From oil of turpentine and iodine (Kekulé a. Bruylants, *B.* 6, 437) or chlorine (Naudin, *Bl.* [2] 87, 111).—6. From oil of turpentine and  $\text{H}_2\text{SO}_4$  or  $\text{Et}_2\text{SO}$  (Riban, *Bl.* [2] 20, 100, 244; Wright, *C. J.* 26, 700; *C. N.* 29, 41; Paternò, *G.* 4, 113; Bruère, *C. R.* 90, 1428; Richter, *B.* 6, 1257).—7. From absinthol and  $\text{P}_2\text{S}_5$  (Faust a. Homeyer, *B.* 7, 1427; Graebe, *B.* 5, 680; Beilstein a. Kupfer, *A.* 170, 282).—8. From menthene  $\text{C}_{10}\text{H}_{16}$ , and Br (Wright, *C. J.* 29, 1).—9. By boiling cuminic alcohol with zinc-dust (Kraut, *A.* 192, 224).—10. From *p*-bromo-toluene, *n*-propyl-bromide, and sodium (Fittig, Schäffer, a. König, *A.* 149, 334; Fittica, *A.* 172, 320; Jacobsen, *B.* 11, 2049).—11. According to Bouchardat (*C. R.* 90, 1560), cymene may be obtained from valerylene (derived from amyl alcohol) by heating it to  $250^\circ$  and treating the resulting divalerylene  $\text{C}_{10}\text{H}_{16}$  with Br in  $\text{CS}_2$ .—12. By passing steam into cymene-sulphonic acid dissolved in diluted  $\text{H}_2\text{SO}_4$ , hydrolysis begins at  $130^\circ$  (Armstrong a. Miller, *C. J.* 45, 148).

**Spectrum.**—Absorption bands in ultra-violet, a narrow one at cadmium-line 17, and a broad band between Cd 17 and Cd 18. The first band enables the presence of cymene in essential oils to be detected and estimated, for it is visible when diluted with 20,000 volumes of alcohol, and examined in a column 15 mm. long (Hartley, *C. J.* 37, 676).

**Reactions.**—1.  $\text{H}_2\text{SO}_4$  and  $\text{K}_2\text{Cr}_2\text{O}_7$  give terephthalic acid.—2. Oxidised by air, in presence of aqueous  $\text{NaOH}$ , to cuminic acid. In this reaction Pr changes to Pr.—3. The urine of animals who have been given doses of cymene contains cuminic acid, together with small quantities of cuminic acid (Jacobsen, *B.* 12, 1512; cf. Nencki a. Ziegler, *B.* 5, 749). Here, also, *n*-propyl becomes isopropyl.—4.  $\text{KMnO}_4$  gives oxy-isopropyl-benzoic acid [c. 153°], as well as terephthalic acid (Riemsen a. Emerson, *Ann.* 8, 267). 5.  $\text{HNO}_3$  forms *p*-tolyl methyl ketone and *p*-toluic acid.  $\text{HNO}_3$  containing nitrous fumes forms ' $\beta$ -nitrocymene'  $\text{C}_{10}\text{H}_9\text{N}_2\text{O}$  [125°] (Holleman, *R. T. C.* 6, 60).—6. Converted by  $\text{AlCl}_3$  at 150° into toluene and other products (Anschütz, *A.* 235, 191). Liquid compounds ( $\text{C}_{10}\text{H}_{11}$ ),  $\text{AlCl}_3$  and ( $\text{C}_{10}\text{H}_{11}$ ),  $\text{Al}_2\text{Br}_6$  may be prepared (Gustavson, *J. R.* 11, 81).  $\text{Al}_2\text{Br}_6$  in presence of Br, ultimately forms penta-bromo-toluene and isopropyl bromide (Gustavson, *B.* 10, 1101). In this reaction the PrBr first formed is changed by the  $\text{AlBr}_3$  into PrBr.—7. By the action of  $\text{CrO}_2\text{Cl}_2$  and treatment of the compound with water, it gives *p*-tolyl-propionic aldehyde (Richter a. Schüchner, *B.* 17, 1931; cf. Etard, *B.* 16, 2921; *A. Ch.* [5] 22, 258).

**Cymene hezahydride**  $\text{C}_{10}\text{H}_{16}$  (172°). S.G. 12-812. Occurs in oil of resin (Renard, *A. Ch.* [6] 1, 230).

**$\alpha$ -Cymene**  $\text{C}_{10}\text{H}_{16}$  [1:2].  *$\alpha$ -Propyl-toluene*. (182° uncor.). From *n*-propyl bromide,  $\alpha$ -bromo-toluene, and sodium (Claus a. Hansen, *B.* 13, 897).

***m*-Cymene**  $\text{C}_{10}\text{H}_{16}$  [1:3]. **m*-Propyl-toluene*. (177°). S.G. 12-863. From *m*-bromo-toluene, *n*-propyl bromide, and sodium (Claus a. Stusser, *B.* 13, 899).

***m*-Isocymene**  $\text{C}_{10}\text{H}_{16}$  [1:3]. (175°). S.G. 865. Occurs in the essential oil obtained by distilling resin of fir trees (Kelbe, *A.* 210, 1; Benard, *A. Ch.* [6] 1, 249). Formed from toluene, isopropyl iodide and  $\text{AlCl}_3$  (Kelbe, *A.* 210, 1). Formed also, together with ordinary cymene, by the dehydration of camphor (Spica, *G.* 12, 543; Armstrong a. Miller, *B.* 16, 2258).

**Preparation.**—Essence of resin is washed with aqueous  $\text{NaOH}$  (to remove phenols), distilled with steam, shaken with dilute and afterwards with conc.  $\text{H}_2\text{SO}_4$  in the cold, washed again with  $\text{NaOH}$  and distilled with steam. It is then sulphonated with a mixture of  $\text{H}_2\text{SO}_4$  (4 pts.) and fuming  $\text{H}_2\text{SO}_4$  (1 pt.) at 90°. The sodium salt of the  $\beta$ -o-cymene sulphonic acid is decomposed by heating with conc.  $\text{HCl}$  for two days at 185°, and the liberated cymene distilled over with steam (Kelbe a. Warth, *A.* 221, 158).

**Reactions.**—1. Oxidised by chromic acid or permanganate to isophthalic acid (Zeigler a. Kelbe, *B.* 13, 1309).—2. Dilute  $\text{HNO}_3$  forms *m*-toluic acid or aldehyde. Fuming  $\text{HNO}_3$  forms a tri-nitro-derivative [72°].—3.  $\text{CrO}_2\text{Cl}_2$  forms a

chocolate-brown powder whence water liberates *m*-toluic acid.

***p*-Isocymene**  $\text{C}_{10}\text{H}_{16}$  [1:4]. (173°). S.G. 869; 28-862. From *p*-bromo-cumene,  $\text{MeI}$ , and sodium (Jacobsen, *B.* 12, 429; R. Meyer, *A.* 220, 27), or from isopropyl chloride, toluene, and  $\text{AlCl}_3$  (Silva, *Bl.* [2] 43, 321).

**CYMENE-AZO-CYMENE** v. AZO-COMPOUNDS.

**CYMENE-CARBOXYLIC ACID**  
**C<sub>10</sub>H<sub>16</sub>MePrCO<sub>2</sub>H** [63°]. Prepared by fusing the amide with potash, or preferably by heating it with concentrated hydrochloric acid at 180°. Crystallises in slender needles isomeric with Rossi's homo-cuminic acid (Paternò a. Spica, *G.* 9, 400).

**Amide**  $\text{C}_{10}\text{H}_{16}\text{MePrCONH}_2$  [139°]. Formed from potassium cymene sulphonate by fusing with  $\text{KCy}$  and treating the resulting crude nitrile with alcoholic  $\text{KOH}$  (Paternò a. Fileti, *G.* 5, 30). Needles, sl. sol. cold water, v. sol. alcohol and ether.

***m*-Cymene carboxylic acid**  $\text{C}_{10}\text{H}_{16}\text{PrCO}_2\text{H}$  [25:1]. [75°]. From the nitrile which is formed from tri-*c*-vinyl phosphate and  $\text{KCyl}$  (Kreysler, *B.* 18, 1711). Needles (from dilute alcohol). V. sl. sol. cold water.— $\text{AgA'}$ .

**Nitrile**  $\text{C}_{10}\text{H}_{16}\text{MePrCN}$ . (245°).

**CYMENE SULPHONIC ACID**  
**C<sub>10</sub>H<sub>16</sub>MePr(SO<sub>3</sub>H)** [1:4:2]. From cymene sulphonic chloride, water, and zinc-dust. Syrup (Berger, *B.* 10, 977).— $\text{KA'}$  8 aq.— $\text{AgA'}$ .

**CYMENE ( $\alpha$ )-SULPHONIC ACID**

**C<sub>10</sub>H<sub>16</sub>MePr(SO<sub>3</sub>H)** [1:1:2]. Formed, together with the ( $\beta$ )-isomeride, by shaking cymene with conc.  $\text{H}_2\text{SO}_4$  or  $\text{ClSO}_3\text{H}$  at 90° (Gerhardt a. Cahours, *A. Ch.* [3] 1, 106; Delalande, *A. Ch.* [3] 1, 368; H. Muller, *B.* 2, 130; Jacobsen, *B.* 11, 1060; Claus a. Cratz, *B.* 13, 901; 14, 2141; Spica, *G.* 11, 201; *B.* 14, 652; Sieveling, *A.* 106, 260; Beilstein, *A.* 170, 287; Paternò, *B.* 7, 591; *G.* 3, 514; Krant, *A.* 192, 226; Benard, *A.* 220, 18). Also formed by debromination of bromo-cymene sulphonic acid obtained from cymidine (Widmann, *B.* 19, 249).

Tables (from dilute  $\text{H}_2\text{SO}_4$ ). The crystals contain 2 aq. and melt at 51° (S.) or 79° (C.); when anhydrous they melt at 220° (C.). The K salt is oxidised by  $\text{KMnO}_4$  to oxy-isopropyl-sulpho-benzoic acid  $\text{C}_{10}\text{H}_{16}(\text{CO}_2\text{H})(\text{SO}_3\text{H})\text{CMe}_2(\text{OH})$ .  $\text{HNO}_3$  forms sulpho-*p*-toluic acid. Potash-fusion forms carvacrol. By treatment in aqueous solution with bromine it yields bromo-cymene  $\text{C}_{10}\text{H}_{16}\text{PrMeBr}$  [4:1:2] and bromo-cymene-sulphonic acid  $\text{C}_{10}\text{H}_{16}\text{PrMeBr}(\text{SO}_3\text{H})$  [4:1:5:2] (Kelbe a. Koschnitzsky, *B.* 19, 1730).

**Salts.**— $\text{KA'}$  aq.— $\text{NaA'}$  3 aq. (Paternò, *G.* 8, 291).— $\text{NaA'}$  5 aq.— $\text{BaA'}$  3 aq. S. (of  $\text{BaA'}$ ) 2:5 at 12° (S.). Pointed leaflets, crystallising readily; m. sol. 90 p.c. alcohol.— $\text{CaA'}$  2 aq. monoclinic crystals,  $\alpha:\beta::1:374:1:124$ ;  $\beta::95^\circ 13'$  (Jero-fejeff, *A.* 170, 297).— $\text{PbA'}$  3 aq. S. (of  $\text{PbA'}$ ) 1:3 to 1:9.— $\text{NiA'}$  5 aq.

**Amide**  $\text{C}_{10}\text{H}_{16}\text{MePr(SO}_2\text{NH}_2)$ . [112°] (J.); [116°] (Kelbe, *B.* 19, 1969).—

**C<sub>10</sub>H<sub>16</sub>MePr(SO<sub>2</sub>NHAg)** (Berger, *B.* 10, 976).

**Benzoyl-amide**  $\text{C}_{10}\text{H}_{16}\text{MePr(SO}_2\text{NHBz)}$ .

[153°] (Wolkoff, *B.* 5, 142).

**Cymene ( $\beta$ )-sulphonic acid**  $\text{C}_{10}\text{H}_{16}\text{Pr(SO}_3\text{H)}$  [1:4:3]. [131°]. Formed, in small quantity, in the sulphonation of cymene (Claus a. Cratz, *B.* 13, 901; 14, 2111). Formed also by debromina-

on of bromo cymene sulphonic acid (Remsen Day, *Am.* 5, 154; v. also Kelbe a. Koschnitzky, 19, 1730; Claus a. Christ, B. 19, 2165). Granules; extremely sol. water, sol. alcohol, insol. ether.

**Salts.**—NaA' aq. — KA' aq. — CaA', 2aq. — BaA', 3aq (over H<sub>2</sub>SO<sub>4</sub>). Gelatinous; v. e. sol. water, sol. alcohol. —PbA', 3aq: amorphous, v. e. ol. water. —CuA', aq.

**Amide** C<sub>6</sub>H<sub>4</sub>MePr.SO<sub>2</sub>NH<sub>2</sub>. [148°].

**o-Cymene (a)-sulphonic acid** C<sub>6</sub>H<sub>4</sub>MePr(SO<sub>3</sub>H) 1:2:2x. Formed, together with the following, by sulphonating o-cymene, especially at low temperatures (Claus a. Hansen, B. 13, 897). —KA' ½aq. 3aA' aq: stellate groups of laminae. —CuA', 4aq. **o-Cymene (β)-sulphonic acid** C<sub>6</sub>H<sub>4</sub>MePr(SO<sub>3</sub>H) 1:2:2x. Formed as above. —BaA', 2aq: gelatinous mass, v. e. sol. water.

**Amide.** Very slender needles (from water).

**m-Cymene (a)-sulphonic acid**

C<sub>6</sub>H<sub>4</sub>MePr(SO<sub>3</sub>H) [1:3:2x]. Formed, together with the (β)-isomeride, by warming m-cymene with conc. H<sub>2</sub>SO<sub>4</sub> (Claus a. Stusser, B. 13, 899). —KA', —CaA', 2aq. —BaA', aq: laminae. S. (of BaA') 43 at 17°. —PbA', 3aq. —CuA', 4aq.

**m-Cymene (β)-sulphonic acid**

C<sub>6</sub>H<sub>4</sub>MePr(SO<sub>3</sub>H) [1:3:2x]. Formed as above. —BaA', aq: needles. S. (of BaA') 3-83 at 16°.

**m-Isocymene (a)-sulphonic acid**

C<sub>6</sub>H<sub>4</sub>MePr(SO<sub>3</sub>H) [1:3:3]. [89°]. Formed, together with the (β)-isomeride, by treating isocymene with conc. H<sub>2</sub>SO<sub>4</sub> (Kelbe, A. 210, 30; B. 15, 39; Spica, G. 12, 497, 546). Deliquescent micaceous leaflets. Br in the cold gives bromo-isocymene sulphonic acid, but at 40° it forms (6,1,3)-bromo-isocymene. KOH and KMnO<sub>4</sub> gives oxy-isopropyl-sulpho-benzoic acid.

**Salts.**—NaA' aq. —KA' 3aq. —KA' (Armstrong a. Miller, B. 16, 2258). —BaA', aq: pearly plates, v. sl. sol. cold, sl. sol. hot, water. S. 37 (Spica). BaA', plates (Bonar, A. 220, 33). —PbA', aq. S. 1-3 at 22° (Spica). —CuA', 2aq. —CuA', 4aq. —NiA', 5aq.

**Amide** C<sub>6</sub>H<sub>4</sub>MePr.SO<sub>2</sub>NH<sub>2</sub>. [73°] (K.); [75°]

(S.). Laminae, sl. sol. boiling water.

**m-Isocymene (β)-sulphonic acid**

C<sub>6</sub>H<sub>4</sub>MePr(SO<sub>3</sub>H) [1:3:4].

**Formation.**—1. By sulphonation of isocymene. —2. By sulphonation of (a)-bromo-isocymene and removal of the Br by sodium amalgam (Kelbe a. Czarnomski, B. 17, 1746; A. 235, 285).

**Salts.**—NaA' 3aq. —BaA', 8aq: laminae, v. e. sol. water. —CaA', 5½aq. —CuA', 3½aq. —PbA', 8aq.

**Amide** C<sub>6</sub>H<sub>4</sub>MePr(SO<sub>2</sub>NH<sub>2</sub>) [162°].

**p-Isocymene (a)-sulphonic acid**

C<sub>6</sub>H<sub>4</sub>MePr(SO<sub>3</sub>H) [1:4:2]. From isocymene and H<sub>2</sub>SO<sub>4</sub>, together with the (β)-isomeride (Jacobsen, B. 12, 431). KOH and potassium permanganate converts it into oxy-propyl-sulpho-benzoic acid C<sub>6</sub>H<sub>4</sub>(CO<sub>2</sub>H)(CO<sub>2</sub>H)Me<sub>2</sub>SO<sub>3</sub>H (R. Meyer a. H. Bonar, A. 220, 30). Potash-fusion gives oxy-terephthalic acid and oxy-cuminic acid [88°].

**Salts.**—BaA', aq: slender needles. S. 4-23 at 0°. —CuA', 4aq: blue leaflets.

**Amide** C<sub>6</sub>H<sub>4</sub>MePr(SO<sub>2</sub>NH<sub>2</sub>). [98°].

**p-Isocymene (β)-sulphonic acid**

C<sub>6</sub>H<sub>4</sub>MePr(SO<sub>3</sub>H). Formed as above. Its Ba salt is extremely soluble in water.

**Amide** C<sub>6</sub>H<sub>4</sub>MePr(SO<sub>2</sub>NH<sub>2</sub>). [80°-90°].

**Cymene disulphonic acid** C<sub>6</sub>H<sub>4</sub>MePr(SO<sub>3</sub>H)<sub>2</sub>. From cymene and fuming H<sub>2</sub>SO<sub>4</sub> (Kraut, A. 192,

226). —BaA' aq: v. e. sol. water (Claus, B. 14, 2140).

**m-iso-CYMENOL** C<sub>6</sub>H<sub>4</sub>PrMe(OH) [4:2:1].

*Methyl-isopropyl-phenol* *m-isocymenol*.

(231°). R<sub>∞</sub> 1.52. From m-isocymene sulphonic acid (1 pt.) by fusion with KOH (6 pts.) (Kelbe, A. 210, 40). Liquid, smelling like thymol. Gives a violet colour with FeCl<sub>3</sub>. By KOH fusion it is converted into o-oxy-isophthalic acid and p-cuminol-carboxylic acid C<sub>6</sub>H<sub>4</sub>Pr(OH)CO<sub>2</sub>H [4:1:2].

**Benzoyl derivative** C<sub>6</sub>H<sub>4</sub>PrMe(OBz).

[73°]. Monoclinic crystals; a:b:c = 52:1:82; β = 82° 17'.

**Methyl ether** C<sub>6</sub>H<sub>4</sub>PrMe(OMe): (217°).

**Ethyl ether** C<sub>6</sub>H<sub>4</sub>PrMe(OEt): (224°).

**Tri-bromo-derivative** C<sub>6</sub>H<sub>4</sub>PrMe(OH): [222°]; plates (Jesurun, B. 19, 1413).

**Isomerides:** CARVACROL and THYMOL.

**m-iso-CYMENOL-CARBOXYLIC ACID**

C<sub>6</sub>H<sub>4</sub>PrMe(OH)CO<sub>2</sub>H [1:3:4:5]. *Cymenotic acid*. [147°]. Formed by the action of CO<sub>2</sub> upon sodium m-iso-cymenol (m-isopropyl-phenol). Long slender needles (from hot water). Sl. sol. hot water, nearly insol. cold water. FeCl<sub>3</sub> produces a bluish-violet colouration.

**Salts.**—AgA': small needles, m. sol. hot water. —BaA', 4aq: needles, v. sol. alcohol.

**Methyl ether A' Me:** [148°]; short needles (from alcohol) (Jesurun, B. 19, 1414).

**Isomerides:** CARVACROTIC and THYMOTIC ACIDS.

**CYMIDINE** C<sub>6</sub>H<sub>4</sub>(C<sub>3</sub>H<sub>7</sub>)(CH<sub>3</sub>)NH<sub>2</sub> [4:1:3].

**Preparation.**—Nitro-cymylene-dichloride C<sub>6</sub>H<sub>4</sub>(C<sub>3</sub>H<sub>7</sub>)(NO<sub>2</sub>)(CHCl<sub>2</sub>), obtained by the action of PCl<sub>5</sub> on nitrocuminic aldehyde, is reduced with zinc and HCl.

**Properties.**—Colourless oil. Volatile with steam. Sol. alcohol and ether. Stable towards oxidising agents. By nitrous acid it is converted into thymol.

**Salts.**—B'HCl: fine needles. —(B'HCl)<sub>2</sub>PtCl<sub>2</sub>: sparingly soluble yellow needles. —B'<sub>2</sub>H<sub>2</sub>SO<sub>4</sub> 2½aq: small white needles, sl. sol. cold water.

**Acetyl derivative.** [about 112°]. White needles (Widman, D. 15, 167; 21, 2126; cf. Barlow, A. 98, 248; P. M. [4] 10, 454).

**Cymidine** C<sub>6</sub>H<sub>4</sub>PrMe(NH<sub>2</sub>) [4:1:2]. From (2,4,1)-nitro-cymene (Löderbaum, B. 21, 2127).

—B'HCl. —B'<sub>2</sub>H<sub>2</sub>SO<sub>4</sub> aq.

**m-Isocymidine** C<sub>6</sub>H<sub>4</sub>PrMe(NH<sub>2</sub>) [3:1:5 or 6]. (233°). From nitro-iso-cymene (Kelbe a. Warth A. 221, 163). Yellowish oil. V. sl. sol. water, v. sol. alcohol, light petroleum, or benzene.

**Salts.**—B'<sub>2</sub>H<sub>2</sub>SO<sub>4</sub>. Sl. sol. water. —B'<sub>2</sub>H<sub>2</sub>CO<sub>3</sub>.

**Acetyl derivative** C<sub>6</sub>H<sub>4</sub>PrMeNHAc [118°].

**Benzoyl derivative** C<sub>6</sub>H<sub>4</sub>PrMeNHBz [165°].

**Phthalyl derivative**

C<sub>6</sub>H<sub>4</sub>C<sub>6</sub>O<sub>4</sub>NC<sub>6</sub>H<sub>4</sub>PrMe. [145°].

**(?n)-CYMIDINE-SULPHONIC ACID**

C<sub>6</sub>H<sub>4</sub>Me(C<sub>3</sub>H<sub>7</sub>)(NH<sub>2</sub>)SO<sub>3</sub>H [1:4:3:6]. Formed by heating cymidine with fuming H<sub>2</sub>SO<sub>4</sub>. Thin glistening colourless plates or prismatic needles. V. sl. sol. cold water. Insol. alcohol. Is probably a n-propyl-derivative, since by treatment of the diazo-compound with HBr and debromination it gives rise to the sulphonic acid of n-cymene. The corresponding

**Diazo-compound**  $C_6H_5MePr \begin{matrix} SO_2 \\ | \\ N_2 \end{matrix}$  forms

small white needles, v. e. sol. water, sl. sol. alcohol, insol. ether. By warming with absolute alcohol it is converted into the sulphonic acid of the ethyl-ether of thymol (Widmann, *B.* 19, 246).

**Isocymidine sulphonic acid**  
 $C_6H_5MePr(NH_2)(SO_3H)$ . From amido-iso-cymene and fuming  $H_2SO_4$  (Kelbe a. Warth, *A.* 221, 177). Salt.—BaA<sup>+</sup>.

**CYMINYL**. Also called CYNYL (*q. v.*).

**CYMOFENOL** v. CYMENOL.

**CYMOFENONE** v. PHENYL CYNYL KETONE.

**CYMYL**. The radicle  $C_6H_5Me(C_6H_5)$ . Its derivatives are described below; see also CARVACRYL and THYMYL compounds. Cumyl  $C_6H_5(C_6H_5)CH_2$  is isomeric with cymyl.

**CYMYLAMINE** v. THYMYLAMINE and CARVACRYLAMINE.

**ISOCYMYL-CARBAMIC ETHER**

$C_6H_5PrMeNH.CO_2Et$ . [229°]. From  $ClCO_2Et$  and amido-iso-cymene. Slender needles (from alcohol).

**ISOCYMYL CARBAMINE**  $C_6H_5PrMeNC$ . From amido-iso-cymene,  $KOH$ ,  $CHCl_3$ , and alcohol (Kelbe a. Warth, *A.* 221, 170). Oil of very nasty odour, nearly insol. water, sol. alcohol, ether, and benzene. Can be distilled with steam, but not alone at ordinary pressure.

**DI-CYMYL ETHYLENE DIKETONE**

$(C_6H_5MePr.CO)_2C_2H_4$ . (c. 320°). From cymene, succinyl chloride, and  $AlCl_3$  (Claus, *B.* 20, 1378).

**ISOCYMYL ETHYL GUANIDINE**

$C_6H_5PrMeNH.C(NH).NHEt$ .

From  $C_6H_5PrMeNH.CS.NHEt$ , alcoholic  $NH_3$ , and  $PbO$  (K. a. W.). Gummy mass.

**Tribenzoyl derivative**

$C_6H_5PrMeNBzC_6H_5(NBz)_2$ . [165°]. Needles (from alcohol).

**CYMYL ETHYL KETONE CARBOXYLIC ACID**  $C_6H_5(C_6H_5)Me.CO.CH_2.CH_2.CO_2H$ . From cymene, succinyl chloride,  $CS_2$ , and  $Al_2Cl_3$  (Claus, *B.* 20, 1378).—PbA<sup>+</sup>.

**ISOCYMYL ETHYL THIO-UREA**

$C_6H_5PrMeNH.CS.NHEt$ . *Methyl-iso-propyl-phenyl-thio-ethyl-urea*. Formed by heating amido-iso-cymene with ethyl-mustard oil. An amorphous gummy mass (K. a. W.).

**CYMYL METHYL KETONE**

$OH.CO.C_6H_5MePr$  [1:2:6]. (248°). From cymene,  $AcCl$ , and  $AlCl_3$  (Claus, *B.* 19, 232).

**DI-ISOCYMYL THIO-UREA**

$(C_6H_5PrMeNH)_2CS$ . [160°]. From amido-iso-cymene and  $CS_2$  in a sealed tube at 100° (K. a. W.). Slender needles (from alcohol).

**ISOCYMYL-UREA**  $NH_2.CO.NH.C_6H_5PrMe$ . *Eso-methyl-eso-iso-propyl-phenyl-urea*. [176°]. From  $KNCO$  and amido-iso-cymene sulphate (Kelbe a. Warth, *A.* 221, 171). Matted glittering needles (from water).

**Di-isocymyl-urea**  $CO(NH.C_6H_5PrMe)_2$ . From  $OCOCl$  and amido-iso-cymene in ether. Slender needles (from alcohol).

**CYNANCHOL**. A crystalline substance extracted by Butlerow (*A.* 180, 349) from *Cynanchum acutum*, a creeping plant growing near the Oxus, and said to poison camels. According to Hesse (*A.* 182, 163) it is a mixture of cynanchocerin [146°] and cynanchin [149°].

**CYNAPINE**. A reddish-yellow oil with powerful odour, contained in the seeds of fool's parsley (*Aethusa cynapium*), whence it may be extracted by distilling with milk of lime. Strongly alkaline in reaction (Ficinus, *Mag. Pharm.* 20, 357; Bernhardt, *Ar. Ph.* [3] 16, 117).

**CYNENE** v. CINEKE.

**CYNEOL** v. CINEOL.

**CYNURENIC ACID** is OXY-QUINOLINE CARBOXYLIC ACID (*q. v.*).

**CYNURIC ACID**  $C_6H_5NO_2$ , i.e.

$CO_2H.C_6H_4.CO.CO_2H$ . *Oxaloxyl-o-amido-benzoic acid*. [189°]. S. 1:12 at 10°. Formed by oxidising cynurenic acid, acetyl-quinoline tetrahydride, or carbostyryl by alkaline  $KMnO_4$  (Kretschy, *M.* 4, 157; Friedländer a. Ostermaier, *B.* 15, 332). Formed also by heating dry oxalic acid with o-amido-benzoic acid at 130° (Kretschy *M.* 5, 21). Needles (from ether).  $Fe_2Cl_6$  colours its aqueous solution crimson. Boiling acids and alkalis split it up into oxalic and o-amido-benzoic acids.

Salts.— $KHA''$  aq.  $-(NH_4)_2A''$ .— $BaHA''$  aq.  $BaA''$  aq.— $CaA''$  2 aq.— $Cu_2A''$  4 aq.— $Ag_2A''$ .

*Ethyl ether EtA'*. [181°]. From indoxyl ether and chromic mixture (Baeyer, *B.* 15, 778). Needles (from alcohol).

**CYSTEIN**  $C_2H_5NSO_3$ , i.e.

$CH_3.C(NH_2)(SH).CO_2H$ . Prepared by adding tin to a solution of cystin in hydrochloric acid (Baumann, *H.* 8, 299). Crystalline powder, sol. water, ammonia, and acids. The aqueous solution is oxidised to cystin even by the air.

**CYSTIN**  $C_2H_5N_2S_2O_6$ , i.e.  $S(CMe(NH_2).CO_2H)_2$ . [ $\alpha$ ]<sub>D</sub> = -206° in 11 p.c.  $HCl$  aq. (Mauthner, *H.* 7, 225); [ $\alpha$ ]<sub>D</sub> = -142° in  $NH_4Aq$  (Kulz, *Z.* B. 20, 1). Occasionally occurs as urinary calculus or sediment (Wollaston, *P.* T. 1810, 223; Golding Bird, *Treatise on Urinary Concretions*; Toel, *A.* 96, 247; Lassaigne, *A. Ch.* [2] 23, 328; Baudrimont a. Malaguti, *J. Ph.* 24, 633; Thaulow, *A.* 27, 197; Marchand, *J. pr.* 16, 254; Robert, *J. Ph.* 7, 165; O. Henry, *J. Ph.* 23, 11; Taylor, *P. M.* [3] 12, 337; Nicmann, *A.* 187, 101; Udranszky a. Baumann, *B.* 21, 2744). Found also in the kidneys of the ox (Cloëtta, *A.* 99, 299) and in the liver of a drunkard who died of typhus fever (Scherer, *N. Jahrb. Pharm.* 7, 306). In very small quantities it is a normal constituent in urine (Goldmann a. Baumann, *H.* 12, 254).

**Properties**.—Neutral and tasteless. Crystalline mass. Insol. water and alcohol; sol. aqueous ammonia (difference from uric acid) and potash, and reppd. as six-sided laminae by  $HOAc$ . Sol.  $HCl$  aq. Separates from an ammoniacal solution as colourless laminae. Cold ammoniacal  $AgNO_3$  followed by  $HNO_3$  gives a canary yellow ppt., but hot ammoniacal  $AgNO_3$  ppt.  $Ag_2S$  (Dewar a. Gamgee, *Ph.* [3] 1, 385). Baryta-water at 150° gives barium sulphide and sulphite. Nitrous acid forms pyruvic acid (Dewar a. Gamgee, *Ph.* [3] 3, 144; *H.* 5, 329). Boiling aqueous  $NaOH$  converts part of its S into  $H_2S$ .

**Benzoyl derivative**  $C_6H_5BzN_2S_2O_6$ . [158°]. Its Na derivative is pptd. by adding  $BzCl$  to a solution of cystin in aqueous  $NaOH$ . Slender needles. Strong acid, insol. water, sl. sol. ether, m. sol. alcohol (G. a. B.).

**CYTISINE**  $C_6H_7N_3O_3$ . [156° cor.]. An alkaloid occurring in the unripe seeds of the laburnum, *Cytisus Laburnum* (Chevallier a. Lassaigne,

Ph. 4, 340; 7, 235; Peschier, *J. Chim. Méd.* 65; Husemann & Marné, *Z.* [2] 1, 161; 5, 7). Crystalline mass (from alcohol) or thin scales and laminae (by sublimation). V. e. sol. in ether and alcohol, nearly insol. ether, benzene, and chloroform. Expels  $\text{NH}_3$  from its salts, even in the cold. Poisonous. Does not reduce Fehling's solution. Potassio-mercuric iodide gives a white flocculent pp. becoming crystalline. I in KI gives an amorphous red pp. changing to prisms. Bromine-water gives an orange pp. even in very dilute (1:15000) solu-

tions. Sodium phosphomolybdate gives a yellow pp. Tannin forms a pp. only after neutralisation with  $\text{NaOH}$ . Picric acid gives a yellow pp. soon becoming crystalline.

**Colour tests.**—Conc.  $\text{H}_2\text{SO}_4$  gives no colour. Sulphomolybdic acid reaction gives no colour.  $\text{H}_2\text{SO}_4$  and  $\text{K}_2\text{Cr}_2\text{O}_7$ , a yellow turning brown.  $\text{HNO}_3$ , an orange-yellow.

**Salts.**— $\text{B}(\text{HNO}_3)_2$ , 2aq: prisms, with bitter taste.— $\text{B}'\text{H}_2\text{Cl}_2$ , 2aq.— $\text{B}'\text{H}_2\text{PtCl}_6$ — $\text{B}'\text{H}_2\text{PtCl}_6$ — $\text{B}'(\text{HAuCl}_4)_2$ — $\text{B}'\text{Hg}_2\text{Cl}_4$ .

## D

**DAMALURIC ACID**  $\text{C}_8\text{H}_8\text{O}_6$ . [53°]. An acid said to have been obtained from cows' urine (Städeler, *A.* 77, 27; Werner, *Z.* [2] 4, 413).

**DAMBONITE**  $\text{C}_8\text{H}_8\text{O}_6$ . [190°]. *Di-methyl-ambrose*. *Di-methyl-inosite*. Occurs in a peculiar kind of caoutchouc. Exported from Gaboon to West Africa (Girard, *C. R.* 67, 820). Six-sided prisms (from alcohol), oblique prisms (containing 3aq) (from water), or slender needles by sublimation). Not affected by dilute acids or alkalis, by Fehling's solution, or by fermentation. HI gives Mel and dambose, identical with inosite. KI forms crystals of  $\text{C}_8\text{H}_8\text{O}_6\cdot\text{KI}$ .  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$  form an explosive nitrate (Champion, *C. R.* 73, 114).

**Acetyl derivative**  $\text{C}_8\text{H}_{12}\text{Ac}_2\text{O}_6$ . [193°]. 387°. Needles (Maquenne, *A. Ch.* [6] 12, 566; *J. R.* 104, 1853).

**Benzoyl derivative**  $\text{C}_8\text{H}_8\text{Bz}_2\text{O}_6$ . [250°]. Minute pale-yellow needles (M.).

**DAMBOSE**  $\text{C}_8\text{H}_{12}\text{O}_6$ . [218°]. Obtained by heating dambonite with aqueous HI at 120° (Girard, *C. R.* 67, 820; 73, 426; 77, 995). According to Maquenne (*C. R.* 104, 1853) it is identical with inosite (*v.* Inositol and Sugars). Six-sided prisms (from dilute alcohol); monoclinic prisms (containing 2aq) (from water). Inactive. V. e. sol. water, insol. absolute alcohol. Not prone to fermentation.

**Hexa-acetyl derivative**  $\text{C}_8\text{H}_8\text{Ac}_6\text{O}_6$ . [211°].

**Methyl ether**  $\text{C}_8\text{H}_8\text{MeO}_6$ , *Bornesite*. [175°]. In caoutchouc from Borneo (Girard, *Z.* [2] 7, 835).

*Di-methyl ether v. DAMBONITE.*

**DAMMARA RESIN.** New Zealand Kauri gum, the gum-resin from *Dammara australis* contains a slightly levorotatory terpene dammarole  $\text{C}_{15}\text{H}_{26}$  (158°) S.G. 1.863 (Bennie, *C. J.* 39, 240; cf. Thomson, *A. Ch.* [3] 9, 499; Muir, *C. J.* 27, 783). Dammar-Puti or East Indian dammara resin may be separated, according to Dulk (*J. pr.* 14, 16), by successive treatment with weak alcohol, absolute alcohol, and ether into hydrated dammarylic acid  $\text{C}_{15}\text{H}_{24}\text{O}_7$  [50°], anhydrous dammarylic acid  $\text{C}_{15}\text{H}_{22}\text{O}_7$  [60°], and dammaryl  $\text{C}_{15}\text{H}_{22}$  [190°], the residue being  $\text{C}_{15}\text{H}_{24}\text{O}$  [215°]. Franchimont obtained an acid  $\text{C}_{15}\text{H}_{24}\text{O}_7$ . See also Schrötter, *P.* 59, 37.

**DANAÏN**  $\text{C}_{15}\text{H}_{24}\text{O}_7$ . Said to occur in the root of *Danaë fragrans*, and to give by hydrolysis a

sugar and resinous danaidin (Schlagdenhouffen, *J.* 1885, 1815).

*oxy-coumarin*. [256°]. Prepared by hydrolysis of daphnin, a glucoside occurring in the bark of *Daphne alpina* and *Daphne Mezereum* (Zwenger, *A.* 115, 8; Stünkel, *B.* 12, 109).

**Synthesis.**—By heating molecular proportions of pyrogallol and malic acid with  $\text{H}_2\text{SO}_4$  (twice the weight of the former), and precipitating the melt in cold water (Pechmann, *B.* 17, 988).

**Properties.**—Needles or prisms. Sol. hot water, sl. sol. ether, nearly insol. chloroform, benzene, and  $\text{CS}_2$ . Dissolves in alkalis with a reddish-yellow colour.

**Reactions.**— $\text{FeCl}_3$  gives a green colouration which changes to red on adding  $\text{Na}_2\text{CO}_3$ . Potassio ferricyanide and  $\text{NH}_3$  gives a reddish-yellow colour.  $\text{HNO}_3$  gives an intense red. It reduces  $\text{AgNO}_3$  and Fehling's solution in the cold. Baryta water,  $\text{Zn}(\text{OAc})_2$ , and  $\text{Ph}(\text{OAc})_3$  give yellow pps. After boiling with  $\text{NaHSO}_4$ ,  $\text{FeCl}_3$  gives an intense blue colour.

**Di-acetyl derivative**  $\text{C}_8\text{H}_8\text{O}_2(\text{OAc})_2$ : [129°]; colourless needles, insol. water, sol. other solvents.

**Di-benzoyl derivative**  $\text{C}_8\text{H}_8\text{O}_2(\text{OBz})_2$ : [152°]; fine needles, insol. water and ether, sparingly soluble in alcohol (Pechmann, *B.* 17, 933).

**Mono-ethyl ether**  $\text{C}_8\text{H}_8\text{O}_2(\text{OEt})$ : [155°]; colourless glistening plates, v. sol. alcohol, ether, benzene, and aqueous alkalis, sl. sol. water.

**Di-ethyl ether**  $\text{C}_8\text{H}_8\text{O}_2(\text{OEt})_2$ : [72°]; colourless needles. V. sol. alcohol, ether, and benzene, insol. water and aqueous alkalis (Will a. Jung, *B.* 17, 1081).

**Bromo-daphnetin**  $\text{C}_8\text{H}_8\text{BrO}_2$ .

**Di-ethyl ether**  $\text{C}_8\text{H}_8\text{BrO}_2(\text{OEt})_2$ : [115°]; colourless feathery crystals. Sol. hot alcohol, ether, and benzene, sl. sol. cold alcohol, insol. aqueous alkalis. Formed by bromination of the di-ethyl ether of daphnetin. By boiling with alcoholic KOH it is converted into the di-ethyl-derivative of daphnetilic acid (Will a. Jung, *B.* 17, 1084).

**Tetra-bromo-daphnetin**. *Acetyl derivative*  $\text{C}_8\text{H}_8\text{Br}_4\text{AcO}_2$ . [c. 290°]. From acetyl-daphnetin and Br at 100° (Stünkel).

**$\beta$ -Methyl-daphnetin**  

$$\text{C}_6\text{H}_3(\text{OH})_2 \begin{pmatrix} (1) \text{C}(\text{CH}_3):\text{CH} \\ (2) \text{O} \text{---} \text{CO} \end{pmatrix}$$
 Formed by the action of  $\text{H}_2\text{SO}_4$  on a mixture of aceto-acetic ether and pyrogallol. By boiling with sodium bisulphite till dissolved and then adding  $\text{Fe}_2\text{Cl}_6$  a blue colouration is produced (Pechmann & Cohen, *B.* 17, 2188).

**Daphnetic acid**  $\text{C}_6\text{H}_3(\text{OH})_2\text{CH}:\text{CH}.\text{CO}_2\text{H}$ .  
**Tri-oxy-cinnamic acid.**

**Tri-ethyl derivative**  
 $\text{C}_6\text{H}_3(\text{OEt})_3.\text{C}_2\text{H}_5.\text{CO}_2\text{H}$ : [193°]; colourless crystals. V. sol. hot alcohol, ether, and benzene, insol. water and  $\text{CS}_2$ . Obtained by evaporating the di-ethyl-ether of daphnetin with aqueous  $\text{NaOH}$ , and heating the residue with ethyl iodide. On oxidation with  $\text{KMnO}_4$  it gives tri-ethoxy-benzoic aldehyde and acid (Will a. Jung, *B.* 17, 1086).

**Daphnetilic acid**  $\text{C}_6\text{H}_3\text{O}(\text{OH})_2.\text{CO}_2\text{H}$ .  
**Di-ethyl derivative**  $\text{C}_6\text{H}_3\text{O}(\text{OEt})_2.\text{CO}_2\text{H}$ . [154°]. Fine felted needles. Formed by boiling the di-ethyl ether of bromo-daphnetin with alcoholic  $\text{KOH}$  (Will a. Jung, *B.* 17, 1085).

**DAPHNIN**  $\text{C}_{15}\text{H}_{10}\text{O}_6$ . [c. 200°]. A glucoside occurring in the bark of certain species of *Daphne* (Vauquelin, *A. Ch.* 84, 173; Gmelin a. Baer, *Sch. J.* 35, 1; Zwenger, *A.* 115, 1). Rectangular prisms (containing 2aq) (from water). Sl. sol. cold water, v. sol. boiling alcohol, insol. ether. Alkalis and alkaline carbonates dissolve it, forming a yellow solution, which turns brown in air.  $\text{FeCl}_3$  colours its aqueous solution bluish. It slowly reduces boiling Fehling's solution. Hot solutions are ppd. by basic lead acetate. Emulsin or dilute acids split it up into glucose and daphnetin.

**DATISCIN**  $\text{C}_{25}\text{H}_{20}\text{O}_{12}$ . [180°]. A glucoside occurring in the leaves and roots of *Datisca cannabina*, which are used to dye silk yellow (Braconnot, *A. Ch.* [2] 3, 277; Stenhouse, *Chem. Gaz.* 1856, No. 318; *A.* 98, 166). Silky needles, sl. sol. cold water, v. sol. alcohol, v. sl. sol. ether. Tastes bitter. Resolved by dilute acids into glucose and datiscetin. Bases dissolve it with deep-yellow colour. Lead acetate,  $\text{Fe}_2\text{Cl}_6$ ,  $\text{CuSO}_4$ , and  $\text{SnCl}_4$  ppt. its solution.

**Datiscetin**  $\text{C}_{15}\text{H}_{10}\text{O}_6$ . Formed as above. Tasteless needles, nearly insol. water, v. c. sol. ether.— $\text{C}_6\text{H}_5\text{PbO}$ .

**DATURINE** is identical with **ATROPINE** (*q.v.*).  
**DAVYUM**. According to Kern, some specimens of Russian platinum ores contain a metal which is not Ir, Os, Pd, Pt, Rh, nor Ru (*C. N.* 86, 114). The mother-liquor remaining after separation of Rh and Ir by Bunsen's method (*P. M.* [4] 86, 253) was heated with excess of  $\text{NH}_4\text{Cl}$  and  $\text{NH}_4\text{NO}_3$ ; the dark-red pp. thus obtained was strongly heated, whereby the new metal was obtained as a spongy mass, which fused in the O-H flame to a silver-white button. The ore contained about .045 p.c. of the new metal, to which Kern gave the name *Davyum*. The metal is described as hard, but malleable when heated; s. sol. *aqua regia*, v. sl. sol. boiling  $\text{H}_2\text{SO}_4$ . S.G. 9.880. At. w. about 154. Several salts of this metal are described by Kern. The whole subject requires re-investigation.

M. M. P. M.

**DECACRYLIC ACID v. DECAENOIC ACID.**

#### DECANAPHTHENE v. DECELENE.

***n*-DECANE**  $\text{C}_{10}\text{H}_{22}$ . (169°–170°) at 742 mm.; (107°) at 100 mm. S.G.  $\frac{23}{4}$  .745;  $\frac{20}{4}$  .734; 199 .669. S. (glacial acetic acid) 8 at c. 15°; 20 at 60°. From *n*-octyl bromide,  $\text{EtBr}$  and  $\text{Na}$  (Lachowicz, *A.* 220, 179). Formed also from methyl ennyl ketone by treatment with  $\text{PCl}_5$  and reduction of the product by  $\text{HI}$  and  $\text{P}$ ; and by reducing octoic acid with  $\text{HI}$  and  $\text{P}$  (Krafft, *B.* 15, 1696). Has hardly any smell and no taste. Not attacked by conc.  $\text{H}_2\text{SO}_4$ . Attacked by  $\text{Br}$  only when heated.

**Decane**  $\text{C}_{10}\text{H}_{22}$ . **Inactive di-isomyl.** (158–8° cor.) at 732–8 mm. S.G.  $\frac{23}{4}$  .7216 (Lachowicz, *A.* 220, 172). V.D. 72 (for 71). S. (in glacial acetic acid) 8 at c. 15°; 20 at 65°. S.V. 231.3 (Schiff, *A.* 220, 88). From isomyl iodide and zinc (Frankland, *C. J.* 3, 32). From isomyl bromide or iodide and sodium (Wurtz, *A. Ch.* [3] 44, 275; Grimshaw, *B.* 10, 1602; *C. J.* 32, 260, 687). Formed also by the electrolysis of sodium hexoate (Brazier a. Gossleth, *C. J.* 3, 221). Tasteless, with faint odour. Flashing-point 53°. Not attacked by  $\text{INO}_3$  or conc.  $\text{H}_2\text{SO}_4$ . Gives with bromine decyl bromide, which on distillation splits up into decylene and  $\text{HBr}$ .

**Decane**  $\text{CH}_3\text{MeEt.CH}_2\text{CH}_2.\text{CHMeEt}$ . **Active diamyl.** (160°). V.D. 4.82 (for 4.91). S.G.  $\frac{23}{4}$  .7463.  $[\alpha]_D^{20} = 6.49^\circ$  for 100 mm. at 22°. From active amyl iodide and sodium (Just, *A.* 220, 155).

**Decane** (152°–153°). S.G.  $\frac{21}{4}$  .7187. V.D. 69.4 (for 71). In Galician petroleum (Lachowicz, *A.* 220, 195).

Another decane from same source: (162°–163°). S.G.  $\frac{22}{4}$  .7324.

**Decane**  $\text{C}_{10}\text{H}_{22}$ . (160°) (Pelouze a. Cahours, *A. Ch.* [4] 1, 5); (156°) (Wurtz, *Bl.* 1863, 300; Lemoine, *Bl.* [2] 41, 165). S.G.  $\frac{23}{4}$  .757 (P. a. C.);  $\frac{21}{4}$  .764 (L.). V.D. 4.95. Occurs in American petroleum.

**Decane.** (171°). S.G.  $\frac{13}{4}$  .756. In coal tar (Jacobsen, *A.* 184, 202).

**DECARBUSNIC ACID v. USNETIC ACID.**

**DECENE v. DECELENE.**

**DECENOIC ACID**  $\text{C}_{10}\text{H}_{18}\text{O}_2$ , *i.e.*  $\text{C}_6\text{H}_{13}.\text{CH}:\text{CH}.\text{CH}_2.\text{CO}_2\text{H}$ . [10°]. Formed by distilling the lactone of  $\beta$ -oxy-heptyl-succinic acid (*q.v.*). Oil, hardly soluble in, and lighter than, water. Volatile with steam. Combines with  $\text{HBr}$  (Schneegans, *A.* 227, 91).

Salts.— $\text{BaA}'_2$ ,  $\text{CaA}'_2$ ,  $\text{AgA}'$ .

**Decenoic acid**  $\text{C}_{10}\text{H}_{18}\text{O}_2$ . **Amyl-valeric acid.** (269°). S.G.  $\frac{12}{4}$  .961. From sodium isomylate and  $\text{CO}$  at 165° (Fröhlich a. Geuther, *A.* 202, 297). Oil. The Na salt is deliquescent.

**Decenoic acid**  $\text{C}_{10}\text{H}_{18}\text{O}_2$ . **Amyldecylenic acid.** (242° cor.). S.G.  $\frac{2}{4}$  .9096. Formed by oxidation of the corresponding aldehyde (Borodin, *B.* 5, 481; Hell a. Schoop, *B.* 12, 193). Oil. Oxidised by chromic mixture to acetic and isovaleric acid (Gaess, *B.* 10, 455). The K salt is deliquescent.  $\text{CaA}'_2$ , 3aq; needles (from alcohol).

**Decenoic acid**  $\text{C}_{10}\text{H}_{18}\text{O}_2$ . **Decacrylic acid.** [86°]. S. (cold alcohol) .08; (hot alcohol) 2. Occurs in cork. Amorphous. Acid to litmus (Siewert, *Z.* 1858, 383).

**DECENOIC ALDEHYDE**  $\text{C}_{10}\text{H}_{18}\text{O}$ . **Disovaleric aldehyde.** (c. 189°). S.G.  $\frac{2}{4}$  .861. Formed from isovaleric aldehyde by heating with zinc filings, or by treating with  $\text{Na}$ ,  $\text{KOH}$ ,  $\text{K}_2\text{CO}_3$ , or  $\text{HCl}$  (Borodin, *B.* 2, 552; 5, 481; 6, 988; Riban,

*Bl.* [2] 18, 64; Kekulé, *B.* 3, 135; Gaess a. Hell, *B.* 8, 371). Oil. Does not combine with  $\text{NaHSO}_4$ . Reduces ammoniacal  $\text{AgNO}_3$ .

**DECENYL ALCOHOL**  $\text{C}_{10}\text{H}_{20}\text{O}$  *i.e.*  
 $\text{CH}_3(\text{CH}_2)_8\text{CH}_2\text{OH}$ . *Allyl-di-propyl-carbinol*. (192° i.v.). S.G.  $\frac{2}{4}$  .8602;  $\frac{3}{4}$  .8427. C.E. (15°-29°) .00101. H.C. 1,544,900 (Lougouine, *Bl.* [2] 35, 563). From di-propyl-ketone, zinc, and allyl iodide (Saytzeff, *A.* 196, 109). Oil, smelling like turpentine. Chromic mixture oxidises it to di-propyl-ketone, butyric acid, and propionic acid. Aqueous  $\text{KMnO}_4$  gives  $\text{CO}_2$ ,  $\text{H}_2\text{C}(\text{CH}_3)_2$ ,  $\text{C}_2\text{H}_5\text{OH}$ .

*Acetyl derivative*  $\text{C}_{10}\text{H}_{18}\text{OAc}$ . (210° i.v.). S.G.  $\frac{2}{4}$  .890;  $\frac{3}{4}$  .8733.

**Decenyl alcohol**  $\text{C}_{10}\text{H}_{20}\text{O}$  *i.e.*  
 $\text{CH}_3(\text{CH}_2)_8\text{CH}_2\text{OH}$ . *Allyl-di-isopropyl carbinol*. (170°). S.G.  $\frac{2}{4}$  .8671;  $\frac{3}{4}$  .8177. C.E. (0°-24°) .00095. From di-isopropyl-ketone, allyl iodide, and zinc (Lebedinsky, *J. pr.* [2] 23, 22). Oil, smelling like turpentine.  $\text{KMnO}_4$  gives  $\text{CO}_2$ ,  $\text{H}_2\text{C}(\text{CH}_3)_2$ ,  $\text{C}_2\text{H}_5\text{OH}$  and isobutyric acid. Forms a liquid dibromide.

**Decenyl alcohol**  $\text{C}_{10}\text{H}_{20}\text{O}$ . (c. 191°). From acetone (75 g.), allyl iodide (205 g.), isobutyl iodide (230 g.), and granulated zinc (Schatzky, *J. pr.* [2] 30, 215). Oil.

**DECENYLENE** *v.* DECINENE.

**DECENYLENE TETRABROMIDE** *v.* TETRABROMO-DECINENE.

**DECINENE**  $\text{C}_{10}\text{H}_{18}$ . *Decenylene*. (c. 158°). S.G.  $\frac{2}{4}$  .787;  $\frac{3}{4}$  .774;  $\frac{2}{3}$  .770.  $n_D^{20}$  77.1 to 78.8 (theory 75.8). Formed by heating allyl-di-propyl-carbinol (decenyl alcohol) with  $\text{H}_2\text{SO}_4$  (1 pt.) and water (1 pt.) at 130°. The only product is distilled, and the portion boiling at 150°-170° is distilled over sodium in an atmosphere of  $\text{CO}_2$ . Absorbs oxygen from the air. Combines with bromine forming  $\text{C}_{10}\text{H}_{18}\text{Br}_2$ . Oxidised by chromic mixture gives acetic, propionic and butyric acids (S. Reformatsky, *J. pr.* [2] 27, 389; *Bl.* [2] 40, 185).

**Decinene**  $\text{C}_{10}\text{H}_{18}$ . *Rutylene*. (150°). From diamylene bromide and alcoholic KOH (Bauer, *A.* 135, 344).

**Decinene**  $\text{C}_{10}\text{H}_{18}$ . *Sebacin*. [55°]. (above 800°). Formed by distilling calcium sebacate (Petersen, *A.* 103, 184).

**Decinene**  $\text{C}_{10}\text{H}_{18}$ . (165°). Formed by the action of alcoholic potash on di bromo-decane derived from petroleum (Reboul a. Truchot, *A.* 144, 248).

**Decinene**  $\text{C}_{10}\text{H}_{18}$ . *Hydrocamphene*. [120°]. (160°). A product of the action of sodium on the solid hydrochloride  $\text{C}_{10}\text{H}_{19}\text{Cl}$  derived from turpentine (Montgolfier, *A. Ch.* [5] 19, 115). Inactive.

**Decinene**  $\text{C}_{10}\text{H}_{18}$ . *Hydrocamphene*. [140°] uncor.]. Prepared by the action of sodium and gaseous HCl on a benzene solution of bornyl chloride ( $\text{C}_{10}\text{H}_{17}\text{Cl}$ ), or of camphor-dichloride ( $\text{C}_{10}\text{H}_{16}\text{Cl}_2$ ) (Kachler a. Spitzer, *B.* 13, 615; *M.* 1, 589). White crystalline solid. V. sol. ether, less sol. alcohol and acetic acid. Does not combine with HCl. Very stable towards oxidising agents. Probably identical with the preceding.

**Decinene** (?)  $\text{C}_{10}\text{H}_{18}$ . *Camphine*. (c. 169°). S.G.  $\frac{2}{4}$  .827. Formed by distilling camphor with iodine or HI (Claus, *J. pr.* 25, 264; Weyl, *M.* 1, 96). Br acts upon it by substitution.

**DECINOIC ACID**  $\text{C}_{10}\text{H}_{18}\text{O}_2$ . [52.5°]. (307°) Formed by the action of sodium on butyric ether (Brüggemann, *A.* 246, 132). Long needles.

**DECINYL ALCOHOL**  $\text{C}_{10}\text{H}_{20}\text{O}$  *i.e.*  
 $(\text{CH}_2\text{CH}(\text{CH}_3)_2)_4\text{CPr}(\text{OH})$ . *Di-allyl-propyl-carbinol*. (194°). S.G.  $\frac{2}{4}$  .9707. C.E. (0°-20°). .00082.  $n_D^{20}$  78.7. From *n*-butyric ether, allyl iodide, and zinc; the product being poured into water and distilled (Saytzeff, *A.* 193, 862). Oil, smelling like turpentine.

**Decinyl alcohol**  $\text{C}_{10}\text{H}_{20}\text{O}$  *i.e.*  
 $(\text{CH}_2\text{CH}(\text{CH}_3)_2)_4\text{CPr}(\text{OH})$ . *Di-allyl-isopropyl-carbinol*. (183° i.v.). S.G.  $\frac{2}{4}$  .8647;  $\frac{3}{4}$  .8512. From isobutyric ether, allyl iodide, and zinc (Riabinin a. Saytzeff, *A.* 197, 70; *Bl.* [2] 31, 199). Oxidised by the air.

**Decinyl alcohol** (?)  $\text{C}_{10}\text{H}_{20}\text{O}$ . (176°). From valerylene and diluted  $\text{H}_2\text{SO}_4$  (Reboul, *A.* 143, 373). Oil.

**Decinyl alcohol** (?)  $\text{C}_{10}\text{H}_{20}\text{O}$ . (c. 211°). A product of the action of allyl iodide and zinc on acetic ether (Schestakoff, *J. pr.* [2] 30, 215).

**DECIPPIUM**. According to Delafontaine (*C. R.* 87, 632; 93, 63; *C. N.* 38, 223; 44, 67) *Samarshite* from North Carolina, and *Sipyite* from Virginia, contain an element belonging to the group of the earths, but differing from all the other metals of this class. To this element Delafontaine gave the name *Decippium*. The double sulphate of Dp and K is insoluble in saturated  $\text{K}_2\text{SO}_4$  aq; on this fact is based a method of separating from terbium. Further researches are required before the existence of decippium can be regarded as established (*cf.* EARTH; and EARTHS, METALS OF THE).

**DECOIC ACID**  $\text{C}_{10}\text{H}_{18}\text{O}_2$ . *Capric acid*. Mol. w. 172. [30°]. (269°). S.G.  $\frac{2}{4}$  .930.

*Occurrence*.—1. As glyceryl ether in butter (Chevreul, *Recherches sur les corps gras*) and in cocoa-nut oil (Gorgey, *A.* 66, 295).—2. As isoamyl ether in fusel oil from grapes (Fischer, *A.* 118, 307; Grimm, *A.* 157, 264), and in fusel oil from Scotch whiskey (Rowney, *A.* 79, 236).—3. In Limburg cheese (Ijenko, *A.* 55, 85).—4. To the extent of 5 p.c. in the fatty mass deposited by the water used to extract yolk (*suint*) from wool (Buisine, *C. R.* 105, 614).

*Formation*.—1. By the distillation of oleic acid (Gottlieb, *A.* 57, 63).—2. By oxidation of oleic acid by  $\text{HNO}_3$  (Redtenbacher, *A.* 59, 54).—3. From octyl-aceto-acetic acid (Guthzeit, *A.* 201, 5).

*Properties*.—Slender needles, hardly sol. water, of faint rancid odour. Sol. alcohol and ether.

*Salts*.— $\text{AgA'}$ . Needles from boiling water. Sl. sol. water.— $\text{BaA'}$ . Plates from boiling water. Sl. sol. water, sol. alcohol.— $\text{CaA'}$ .— $\text{MgA'}$ .— $\text{CuA'}$ .— $\text{NaA'}$ . Sol. water.

*Methyl ether*  $\text{MeA'}$ . (224°).

*Ethyl ether*  $\text{EtA'}$ . (244°). S.G. .862.

*Iso-amyl ether* (275°-290°). In fusel oil from grapes.

**Chloride**  $\text{C}_{10}\text{H}_{17}\text{OCl}$ . (c. 210°) (Grimm, *A.* 157, 272).

**Amide**  $\text{C}_{10}\text{H}_{17}\text{ONH}_2$ . [98°]. Prepared by digesting ammonio decanoate at 230° under pressure; the yield is 75 p.c. (Hofmann, *B.* 15, 984).

**DECOIC ALDEHYDE**  $\text{C}_{10}\text{H}_{18}\text{COH}$  (c. 106°) at 15 mm. Formed by distilling a mixture of

barium decate (caprate) and barium formate. Liquid. On reduction with zinc-dust and acetic acid it gives *n*-prim-decyl alcohol (Krafft, *B.* 16, 1716).

Isodecoic aldehyde  $C_{19}H_{38}O$ . (169° cor.). S.G.  $d_{20}^{20}$  0.828. Formed by oxidation of iso-capryl alcohol. Oil. Does not combine with  $NaHSO_3$ , (Borodin, *J.* 1870, 680).

**DECOMPOSITION, CHEMICAL.** The breaking down of one definite kind of matter into simpler kinds is called chemical decomposition. By a definite kind of matter is meant, in chemistry, an element or a compound. The term decomposition can be applied in strictness only to one class of changes undergone by compounds. The products of the decomposition of a compound are either elements or compounds; the mass of each is different from the mass of the compound decomposed, and the properties of each are different from those of the original compound. The simplest cases of chemical decomposition are those brought about by the action of an external agency such as heat, light, or electricity on a compound; water, for instance, is decomposed by the electric current into hydrogen and oxygen; sal ammoniac is decomposed by heat into ammonia and hydrogen chloride. By a slight extension, the term chemical decomposition is used to include cases of chemical interaction between two or more bodies resulting in the formation of new bodies, some at least of which are simpler than the original substances. Thus when water and potassium interact potash and hydrogen are produced; the water is often said to be decomposed by the potassium, inasmuch as one of the products of the interaction is the element hydrogen, which was formerly combined with oxygen forming water. So when acetic acid and phosphorus pentachloride react to produce acetyl chloride, phosphorus oxychloride, and hydrochloric acid, each of the reacting bodies may be said to be decomposed by the other. This example shows that the term chemical decomposition is used as covering the greater number of reactions known as chemical changes. The combination of two elements, or of one element and compound, or of two (or more) compounds, would not generally be called a decomposition; nor would the term be customarily employed with reference to an isomeric or allotropic change, such as that of ammonium cyanate into urea, or of one form of crystalline arsenious oxide into the other form; but with these exceptions the terms chemical decomposition and chemical change have practically the same connotation.

When a chemical change between two or more bodies is called a decomposition, the term is generally used with the object of concentrating attention chiefly on one of the changing substances. Thus the change which occurs when potash solution reacts with chlorine to form potassium chloride and chlorate is a decomposition of the potash, but a combination of the chlorine with other elements. Again, when it is said that common salt is decomposed by sulphuric acid with production of hydrogen chloride, only one part of the chemical change is brought prominently forward; it might be necessary sometimes to say that sulphuric acid is decomposed by common salt with production of sodium sul-

phate; neither statement is a full account of the occurrence.

Among chemical decompositions, in a narrower sense of the term, processes of dissociation take a prominent place. In these processes one definite compound is resolved, by the action of heat, into two or more elements or compounds differing from itself, and each weighing less than the original compound; thus hydrogen iodide is dissociated into hydrogen and iodine, ammonium carbamate is dissociated into ammonia and carbon dioxide, and so on.

Chemical decompositions are special cases of chemical change; the laws which state the conditions and course of chemical changes apply to chemical decomposition. These laws are stated and discussed in other articles; v. especially AFFINITY, vol. i. p. 67; CHEMICAL CHANGE, vol. i. p. 731; COMBINATION, CHEMICAL, LAWS OF; COMPOSITION, CHEMICAL.

M. M. P. M.

**DECONENE**  $C_{10}H_{16}$ . (c. 148°). From dibromo-decylene (rutylen bromide) and alcoholic potash (Bauer a. Verson, *A.* 151, 52; Tugolesoff, *J. R.* 13, 417). Oil, smelling like turpentine. Its bromide  $C_{10}H_{15}Br_2$  gives no cymene when heated with aniline. HCl gives  $(C_{10}H_{15})_2NCl$ .

Isomerides v. TERPENES.

**DECONOIC ACID**  $C_{14}H_{26}O_2$ . Tri-*n*-ethylbutyric acid (?) (c. 255°). Formed by heating  $NaOEt$  and  $NaOAc$  in a current of  $CO$  at 205° (Geuther a. Fröhlich, *A.* 202, 309).

***n*-prim-DECYL-ALCOHOL**  $C_{10}H_{21}OH$ . i.e.  $CH_3(CH_2)_8CH_2OH$ . Mol. w. 158. [7°]. ( $119^\circ$ ) at 15 mm. S.G. (liquid)  $d_{20}^{20}$  0.839;  $d_{25}^{25}$  0.8297;  $d_{40}^{40}$  0.7731. Large rectangular prisms or a thick sweet-smelling highly-refractive liquid.

**Formation.**—Capric aldehyde (obtained by distilling barium caprate with barium formate) is reduced with zinc-dust and acetic acid.

**Acetyl derivative**  $C_{10}H_{21}OAc$  (125° at 15 mm.). Mobile peculiar-smelling liquid. Solidifies at a low temperature (Krafft, *B.* 16, 1716).

**Decyl alcohol**  $C_{10}H_{21}OH$ . *Primyl-carbinol*. (211°). S.G.  $d_{20}^{20}$  0.839;  $d_{25}^{25}$  0.826. From  $\alpha$ -manthol and  $ZnPr_2$  followed by water (Wagner, *Bl.* [2] 42, 330; *J. R.* 16, 329). Oil.

**Decyl alcohol**  $C_{10}H_{21}OH$ . (200°). S.G.  $d_{20}^{20}$  0.858. From the decane of petroleum *via* decyl chloride (Lemoine, *Bl.* [2] 41, 165; cf. Pelouze a. Cahours, *J.* 1863, 523; *A. Ch.* [4] 1, 5).

**Decyl alcohol**  $C_{10}H_{21}OH$ . *Iso-capric alcohol*. (203°). S.G.  $d_{20}^{20}$  0.857. From isovaleric aldehyde and sodium (Borodin, *Z.* 1870, 415).

**Acetyl derivative**  $C_{10}H_{21}OAc$ . (220°). S.G.  $d_{20}^{20}$  0.893.

**Benzoyl derivative**  $C_{10}H_{21}OBz$ . (above 280°).

**Decyl alcohol**  $C_{10}H_{21}OH$ . (c. 230°). S.G. 84. From isoamyl isovalerate and sodium (Lourenço a. Aguiar, *Z.* 1870, 404).

**Acetyl derivative**  $C_{10}H_{21}OAc$ . (c. 232°).

**Decyl alcohol**  $C_{10}H_{21}OH$ . *Diisoamyl alcohol*. (203°). Formed, together with an isomeride (212°), from di-isoamyl (decane), by chlorination and displacement of  $Cl$  by  $OH$  (Grimsshaw, *B.* 10, 1602).

**DECYL BROMIDE**  $C_{10}H_{21}Br$ . From di-isoamyl. Splits up on distillation into  $HBr$  and decylene.

**DECYL CHLORIDE**  $C_{10}H_{21}Cl$ . (200°). From di-isomyl and Cl (Schorlemmer, A. 120, 246).

**Decyl chloride**  $C_{10}H_{21}Cl$ . (c. 202°) (Pelouze & Cahours, A. Ch. [4] 1, 5). S.G. 1.2-908 (Lemoine, Bl. [2] 41, 165). From decane of petroleum and chlorine.

**Decyl chloride**  $C_{10}H_{21}Cl$ . (c. 195°) (Wurtz, Bl. [2] 5, 315). From Cl and the decane from di-bromo-decane (diamylene bromide).

**Decyl chloride**  $C_{10}H_{21}Cl$ . (c. 180°). From decyl alcohol (isocapryl alcohol) (Borodin, J. 1864, 338).

**DECYLENE**  $C_{10}H_{18}$ . *Di-amylene*. (156°-156.3°) at 757.4 mm.; S.G. 0.7789; C.E. (10°-156°) .00121; V.D. 4.86 (for 4.84); S.V. 211.3 (Schiff, A. 220, 90).

**Formation**.—1. From isoamyl alcohol by treatment with  $P_2O_5$  or  $ZnCl_2$  (Cahours, A. 30, 295; Balard, A. 52, 316).—2. From amylene (tri-methyl-ethylene) and  $ZnCl_2$  or conc.  $H_2SO_4$  (Bauer, Sitz. W. 44 [2] 87; Wysznegradsky, J. R. 7, 165; Berthelot, A. 128, 311; Lebedeff, J. R. 7, 246; Erlenmeyer, Z. 1865, 362; Schneider, A. 157, 207).

**Properties**.—Oil. Yields, among the products of its oxidation, amethenic acid  $C_8H_{11}O_2$ .

**Decylene**  $C_{10}H_{18}$ . (163.7° cor.) at 744 mm. S.G. 2.7387. V.D. 70 (calc. 70). From di-isomyl by treatment with Br and distillation of the resulting bromo-di-isomyl (Lachowicz, A. 220, 178). Formed also by distilling decyl acetate (from decyl bromide and NaOAc). Aromatic liquid. Soluble in dilute  $H_2SO_4$  (1:1). Combines readily with Br, but some HBr also comes off. The product is decomposed by distillation.

**Decylene**  $C_{10}H_{18}$ . (c. 159°). S.G. 1.856. From petroleum decane (Lemoine, Bl. [2] 41, 165).

**Decylene**  $C_{10}H_{18}$ . *Decanaphthene*. (161°). S.G. 2.795. R<sub>∞</sub> 77.2. Occurs in petroleum from Baku (Markownikoff & Oglobin, J. R. 15, 332).

**Decylene**  $C_{10}H_{18}$ . (171°). Among the products obtained by strongly heated paraffin (Thorpe & Young, A. 165, 29).

**Decylene**  $C_{10}H_{18}$ . (175°). S.G. 2.791. From blubber by saponification and distillation of the lime salts of the resulting acids (Warren & Storer, Z. 1868, 231).

**Decylene**  $C_{10}H_{18}$ . (176°). S.G. 2.823. From petroleum from Burmah (Warren & Storer, Z. 1868, 231).

**Isomerides v. Tetrahydrides of TERPENES.**

**DECYLENE GLYCOL** v. DR-OXY-DECANE.

**DECYLENE OXIDE**  $C_{10}H_{18}O$ . *Diamylene oxide*. (170°-180°). From  $C_{10}H_{18}(OAc)_2$  and solid KOH (Bauer, Sitz. W. 45 [2] 276). Oil. Reduces ammoniacal  $AgNO_3$ .

**Decylene oxide**  $C_{10}H_{18}O$ . (c. 201°). V.D. 5.3 (calc. 5.4). Formed by the action of conc. KOH on the product of the action of crude amylene on  $Bz_2O_2$  at 110° (Lippmann, M. 5, 563). Does not reduce ammoniacal  $AgNO_3$ , nor combine with  $NaHSO_4$ .

**DEHYDRACTIC ACID**  $C_8H_8O_2$ , i.e.

$CMe.O.CMe$

$\parallel \quad \parallel$  (?) [109°]. (270° cor.). S. 1  
 $CH.CO.C.CO_2H$   
at 0°.

**Formation**.—1. By passing the vapour of aceto-acetic ether through a glass tube filled with pumice and heated to redness (Geuther, Z.

Vol. II.

[2] 4, 655; Perkin, jun., C. J. 47, 240; 51, 489).—2. By the action of pyridine or picoline upon acetyl chloride; these bases probably only act by removing HCl, for they are found unaltered at the end of the reaction (Dennstedt & Zimmermann, B. 19, 75).

**Properties**.—Needles or trimetric tables (from water). V. sol. hot water, hot alcohol, and ether.  $FeCl_3$  colours its solution orange.

**Reactions**.—1. Boiling conc. NaOH aq. splits it up into  $CO_2$ , acetic acid, and acetone. Alcoholic KOH forms, as intermediate products, aceto-acetic ether and acetic acid.—2. Ammonia forms oxy-di-methyl-pyridine (Perkin, B. 18, 682; Haitinger, M. 6, 105).—3. Zn and HCl forms an acid [187°] (Oppenheim & Frecht, B. 9, 1101).—4.  $PCl_5$  forms  $C_8H_8O_2Cl_2$  [101°], reconverted by water at 200° into dehydracetic acid.

**Salts**.— $NaA'$  2aq.— $BaA'$  2aq.— $CaA'_2$ — $ZnA'_2$  2aq.— $AgA'$ .

**Methyl ether**  $MA'$ : [91°]; prisms; v. sol. water. Has distinct acid properties, forming  $C_8H_8(NaO)Me$  (Perkin, B. 18, 218).

**Ethyl ether**  $EA'$ . [92°].

**Amide**  $C_8H_8O.NH_2$ . [209°]. From the acid and aqueous  $NH_3$  (O. a. P.).

**Anilide**  $C_8H_8O.NHPh$ . [115°].

**Oxim**  $C_8H_8O_2(NOH)$ . [173°]; colourless crystals, sol. alcohol. Formed by the action of hydroxylamine on potassium dehydraceticate.  $FeCl_3$  gives a purple-red colouration.

**Phenyl-hydrazide**  $C_8H_8O.C_6H_5.NHPh$ : [c. 207°]; glistening yellow tables (from alcohol). Formed by the action of phenyl-hydrazine on potassium dehydraceticate (Perkin & Bernhart, B. 17, 1522).

**Chloro-dehydracetic acid**  $C_8H_7ClO_2$ . [93°]. From dehydracetic acid and Cl (O. a. P.). Small needles.

**Bromo-dehydracetic acid**  $C_8H_7BrO_2$ , i.e.  $CBr.CO.C.CO_2H$

$\parallel \quad \parallel$  (?) [137°].

$CMe.O.CMe$

**Preparation**.—Dehydracetic acid (5 g.) is dissolved in chloroform (50 g.), a slight excess of bromine and a little iodine are then added, and the whole warmed on the water-bath at about 50°. The reaction once started continues by itself and is finished in about 12 hrs. (Perkin, C. J. 51, 490).

**Properties**.—Plates and prisms. V. sol. hot alcohol, chloroform, benzene, and petroleum-ether, sl. sol. cold alcohol.

**Oxy-dehydracetic acid**  $C_8H_8O_3$ , i.e.

$CO.H.C—CO—C.OH$

$\parallel \quad \parallel$  (?) [c. 253°].

$Me.C—O—C.Me$

**Preparation**.—Bromodehydracetic acid is dissolved in a little alcoholic potash, excess of the latter is then added, and the whole allowed to stand for several days at about 40° (Perkin, C. J. 51, 491).

**Properties**.—Foursided crystals. M. sol. hot alcohol, almost insol. cold water, chloroform, petroleum-ether, benzene, and acetone. Is readily sol. alkalis. Sublimes with slight decomposition.

**Salt**.— $C_8H_8O.Ag_2$  (?).

**Acetyl derivative**  $C_8H_8O(OAc)_2$ . [187°]. Rhomboidal plates. V. sol. hot alcohol, m. sol. benzene, chloroform, ether, and  $CS_2$ .

DEHYDRO-BENZOYL-ACETIC ACID

$\text{CH}_3\text{CO.CCO}_2\text{H}$

$\text{C}_{11}\text{H}_{12}\text{O}_4$ , i.e.  $\parallel \parallel$  (?) [172°]. Prepared by heating benzoyl-acetic ether for 7 or 8 minutes at its boiling-point, alcohol being split off (Baeyer & Perkin, jun., *B.* 17, 64; *C. J.* 47, 262; *Ann.* 8, 101). Long yellow needles. *V.* sol. ether and chloroform, m. sol. alcohol, sl. sol. ligroin.

*Reactions.*—1. By standing with cold alcoholic KOH it is reconverted into benzoyl-acetic acid.—2. It dissolves in cold  $\text{H}_2\text{SO}_4$  with an olive-green colour, and on heating becomes a splendid violet, the spectrum of which exhibits the indigo bands; on dilution with water the colour vanishes.—3. Sodium amalgam reduces it to an acid  $\text{C}_{10}\text{H}_{12}\text{O}_4$  [112°], and an acid  $\text{C}_{10}\text{H}_{11}\text{O}_4$  [145°-150°].—4.  $\text{FeCl}_3$  colours the hot alcoholic solution orange-red.—5. Does not combine with Br.—6. Does not react with  $\text{Ac}_2\text{O}$ . 7. Red-hot soda-lime gives acetophenone.—8. Phenyl-hydrazine forms a yellow compound. 9.  $\text{PCl}_5$  gives  $\text{C}_{10}\text{H}_{11}\text{ClO}_4$  [151°].

*Salts.*— $\text{FeSO}_4$  gives a blackish-violet amorphous pp., and  $\text{FeCl}_3$  gives a deep scarlet pp. in neutral solutions (Baeyer & Perkin, *B.* 17, 64). *A'Ag*: white flocculent pp.

*Ethyl ether EA*. [150°]. Needles. *M.* sol. alcohol, benzene, and  $\text{CS}_2$ , sl. sol. ether and light petroleum.  $\text{FeCl}_3$  colours its alcoholic solution reddish-brown.  $\text{NaOEt}$  added to its ethereal solution forms a sodium derivative.

Derived acid  $\text{C}_{10}\text{H}_{11}\text{O}_4$ , i.e.

$\text{C}:\text{CH}_3\text{CO}_2\text{H}$

$\parallel \parallel$  (?) [112°]. Formed as above

$\text{CPh.O.CPh}$  (Reaction 3). Tables. *V.* sol. alcohol, ether, benzene,  $\text{CS}_2$ , and chloroform, almost insol. light petroleum. Does not decolourise Br in  $\text{CS}_2$  solution. Conc.  $\text{H}_2\text{SO}_4$  gives an intense orange solution which on warming becomes first colourless and then greenish-brown.

Derived acid  $\text{C}_{10}\text{H}_{11}\text{O}_4$ , i.e.

$\text{CH}_3\text{CH}(\text{OH}).\text{C.CO}_2\text{H}$

$\parallel \parallel$  (?) [145°-150°]. Found in

$\text{CPh} - \text{O} - \text{CPh}$  the mother-liquor from which the above has separated. Yellow needles (from alcohol-petroleum). *V.* sol. most solvents, sl. sol. light petroleum and  $\text{CS}_2$ . Gives off  $\text{CO}_2$  on fusion. The  $\text{CS}_2$  solution does not decolourise Br in the cold; on warming  $\text{HBr}$  is given off. Conc.  $\text{H}_2\text{SO}_4$  forms a yellow solution which becomes brownish-red on warming. Boiling  $\text{Ac}_2\text{O}$  forms  $\text{C}_{10}\text{H}_{11}\text{O}_4$  [145°-150°] which crystallises from 80 p.c. acetic acid in yellow needles; it is *v.* sol. hot alcohol, benzene,

and chloroform, but sl. sol. ether; and its alcoholic solution is turned scarlet by  $\text{FeCl}_3$ .

DEHYDROBENZYLIDENEDIACETOACETIC ETHER *v.* BENZYLIDENE-DIACETOACETIC ETHER.

DELPHININE  $\text{C}_{22}\text{H}_{19}\text{N}_3\text{O}_4$  [119°] (Blyth). *S.* 0.2 at 20°; *S.* (alcohol) 5 at 20°; *S.* (ether) 9 at 20°; *S.* (chloroform) 6.3 at 20°. An alkaloid occurring in the seeds of stavesacre, or *Delphinium staphisagria* (Lassaigne & Feneuille, *A. Ch.* 12, 358; Brandes, *Schw. J.* 25, 369; O. Henry, *J. Ph.* 18, 661; Couerbe, *A. Ch.* [2] 52, 352; *A.* 9, 101; Erdmann, *Ar. Ph.* [2] 117, 43; Marquis, *Russ. Zeit. Pharm.* 16, 449, 481, 513). Trimetric crystals (from ether); *a:b:c* = 637:1:804. Decomposes at 120°. Inactive; has a slightly alkaline reaction. Tastes somewhat bitter. Conc.  $\text{H}_2\text{SO}_4$  gradually forms a faintly brown solution changing to reddish-violet. A mixture of delphine (1 pt.) and malic acid (1 pt.) is coloured orange by  $\text{H}_2\text{SO}_4$ , the colour changing through deep rose to blue (Tattersall, *C. N.* 41, 63).

*Salts.*— $\text{B}^2\text{HCl}$ .— $\text{B}^2\text{HAuCl}_4$ .— $\text{B}^2\text{HNO}_3$  (?).— $\text{B}^2\text{HSO}_4$  (?).— $\text{B}^2\text{HHgI}_2$ .

Delphinidine  $\text{C}_{22}\text{H}_{19}\text{N}_3\text{O}_4$  [110°-120°] (?). *S.* 0.17; *S.* (ether) 33. Separates from the ethereal solution out of which delphine has crystallised (Marquis). Miscible with alcohol. Inactive. Tastes bitter. Has an alkaline reaction. With sugar and  $\text{H}_2\text{SO}_4$  it becomes first brown, then green (*cf.* Schneider, *Fr.* 12, 219).  $\text{H}_2\text{SO}_4$  and bromine water give a violet colour.

*Salts.*— $\text{B}^2\text{HCl}$ .— $\text{B}^2\text{HAuCl}_4$ .— $\text{B}^2\text{HSO}_4$ .— $\text{B}^2\text{HNO}_3$ .— $\text{B}^2\text{HOAc}$ .

Delphinine  $\text{C}_{22}\text{H}_{19}\text{N}_3\text{O}_4$  (?). Once found in the mother-liquors, from which delphine had separated. Less soluble than delphinidine which it resembles.

Staphisagrine  $\text{C}_{22}\text{H}_{19}\text{NO}_4$  [*c.* 90°]. *S.* 5; *S.* (ether) 117. Also occurs in stavesacre. Amorphous. Differs from the preceding alkaloids in being much less sol. ether. Soluble in all proportions in alcohol and chloroform. Optically inactive. Has an alkaline reaction. Conc.  $\text{H}_2\text{SO}_4$  gives a cherry-red or violet colour. Does not give a green with sugar and  $\text{H}_2\text{SO}_4$ , or violet with  $\text{H}_2\text{SO}_4$  and Br.  $\text{HNO}_3$  colours it orange.

*Salts.*— $\text{B}^2\text{HCl}$ .— $\text{B}^2\text{HNO}_3$ .— $\text{B}^2\text{HOAc}$ .— $\text{B}^2\text{HAuCl}_4$ .— $\text{B}^2\text{HgI}_2$  (?).— $\text{B}^2\text{HSO}_4$ .

DENSITIES, RELATIVE, of solids, liquids, and gases.—The subject of densities, absolute densities, relative densities, and specific gravities, deals with the following points:—

1. The mass contained in a definite volume of any one substance, or, knowing that weights are proportional to masses, the weights of definite volumes of different substances.

2. The ratio between the mass contained in any volume of a substance and the mass contained in an equal volume of a substance chosen as the standard, or, expressing this somewhat

differently, the ratio between the weight of a certain volume of any substance and the weight of an equal volume of the standard substance.

The terms in which these different ideas are embodied are *density*, *absolute density*, *relative density*, and *specific gravity*. Unfortunately there still exists a great deal of confusion as to the use of these terms, and even the standard text-books do not show agreement on this point. It is, therefore, necessary to give definitions of these terms showing the meanings which will be given to them in this article, and then to indicate wherein there is want of scientific precision in the ordinary use of the terms, and also wherein the meanings given to them in the text-books differ.

1. The *density*, or the *absolute density*, of any substance at any temperature is the mass of unit volume of that substance at that temperature.

Thus, if  $D$ , stands for the absolute density of the substance at temperature  $t$ ,  $M_t$  for the mass of the substance at temperature  $t$ ,  $V_t$  for the volume of the substance at temperature  $t$ , we have the relation  $D_t = \frac{M_t}{V_t}$ ; the numerical value for the absolute density will depend on the units of mass and length employed.

Making use of the notation of dimensional equations as introduced by Maxwell we get

$$[D] = \frac{[M]}{[V]} = [M] [L]^{-3};$$

that is, we find the unit of density to be of one dimension in mass, and of minus three dimensions in length.

2. The *specific gravity*, or the *relative density*, of a substance at any temperature is the ratio of the mass of any volume of the substance to that of an equal volume of some standard substance. The standard substance generally chosen is water at the temperature of its maximum density.

The above definitions show that relative density may be found by comparing the masses of any volume; we may choose the masses of unit volume, but inasmuch as we have given the name of *density* or of *absolute density* to the mass of unit volume, we shall thus get a new definition for specific gravity or relative density, namely,

The *specific gravity* or the *relative density* of a substance at any temperature is the ratio of its absolute density to the absolute density of the standard substance.

Putting  $S$  for the relative density, we get

$$S = \frac{D}{D_1} = \frac{M_1}{M_2} \cdot \frac{V_2}{V_1}; \text{ and, if } V_1 = V_2, \text{ then } S = \frac{M_1}{M_2},$$

where  $M_1$  and  $M_2$  stand for the masses of volumes  $V_1$  and  $V_2$ .

It is evident from the above formula that, inasmuch as  $S$  is the ratio between two masses, its value is independent of the unit chosen for mass. Hence the number expressing the relative density or specific gravity is a pure number, and has no dimensions.

On referring back to the two definitions given above, we find *density* and *absolute density*, *relative density* and *specific gravity*, used as

synonymous terms. It does not matter which of them we employ, but it is better to make a definite choice at the outset and to abide by it. Absolute density goes with relative density, and density with specific gravity. The terms *absolute density* and *relative density* will be used in this article. Unfortunately the terms *density* and *specific gravity* are often used as synonymous, specific gravity being applied to solids and liquids and density to gases. To give the same meaning to two terms which express entirely distinct ideas is quite unpardonable. Attention has been drawn to this unscientific use of scientific terms in some of the more recent standard text-books, but there is still a difference of opinion as to the advisability of using the term specific gravity in preference to relative density, or *vice versa*. Agreement on this point would be desirable.<sup>1</sup>

We have found that the numerical value for the absolute density depends on the system of units employed, while that of the relative density is the same whatever the system of units. If we use the C.G.S. system of units, as is now done in scientific work, we find that there is a definite relation between the unit of mass and the unit of volume, the unit of mass being the mass of unit volume of water at the temperature of its maximum absolute density. Therefore the maximum absolute density of water is equal to unity, and the relative density of any substance when referred to water at its maximum absolute density as standard is expressed by a number which is identical with that of its absolute density. Thus, taking the case of gold, its absolute density in the C.G.S. system of units is 19.2 grams, i.e. 1 c.c. of gold weighs 19.2 grams; the relative density of gold is also 19.2, that is, the mass contained in any volume of it is 19.2 times as great as that contained in an equal volume of water.

There are evidently two main methods for experimentally determining the relative density of any substance.

1. Determine its absolute density, that of the standard being known.

2. Determine the ratio of the mass of the substance to that of an equal volume of the standard.

A short account of the principles underlying the most important methods for determining relative densities is all that can be given here. For detailed accounts of the relative values of the various methods and for the necessary experimental precautions books on practical physics must be consulted. (The article *Dichte* in Ladenburg's *Handwörterbuch der Chemie*, 8, 281-280, is particularly complete.)

I. RELATIVE DENSITIES OF SOLIDS.—The standard substance is water at the temperature of its maximum density. It is not easy to produce this temperature and maintain it constant; however, we know accurately the density of water

<sup>1</sup> The German equivalents of density (*Dichtigkeit*) and specific gravity (*Spezifisches Gewicht*) are used in exactly the same sense as in English. There seems to exist a great deal of ambiguity about the use of the French terms *densité* and *pois spécifique*. The two are used as synonymous, or, if a difference is made, this consists in defining *densité* as the mass contained in unit volume, and *pois spécifique* as the weight of unit volume (*v. Dictionnaire des quelques propriétés générales des corps*).

at various temperatures, so that we can always calculate what the mass of water at the temperature of the experiment would become at the temperature of maximum density.

1. *Experimental processes based on the first method*, that is, on determining the absolute density, that of water being known. — Using the C.G.S. system of units we find the absolute and the relative density to be numerically the same. From the formula  $D = \frac{M}{V}$  we see that the experimental work consists in determining (a) a mass, that is practically a weight, (b) a volume. The following methods are used in practice.

(i.) The body is weighed in air and then thrown into a graduated vessel partly filled with liquid. The difference in readings before and after introduction of the solid gives its volume. The weight in grams divided by the volume in cubic centimetres gives the absolute density which is numerically equal to the relative density.

(ii.) By means of the *stereometer* or *volume-meter*. The use of this apparatus is based on the assumption of the truth of Boyle's law, according to which pressure  $\times$  volume = constant, when temperature is constant. (For a description of the instrument reference must be made to a manual of practical physics.)

2. *Experimental processes based on the second method*, that is, on determining the ratio between the mass of the substance and the mass of an equal volume of the standard substance.

(i.) *The specific gravity bottle*.—The form and capacity of this instrument vary widely, according to the special purpose for which it is used. Generally it is a small flask of thin glass which will hold a definite volume of liquid. The amount of liquid is adjusted either by filling the flask up to a mark on the neck or by filling it completely and inserting a perforated stopper through which excess of liquid flows out. The observations necessary are:

(a) The weight of the flask filled with distilled water  $W_1$   
(b) The weight of the solid in air  $W$   
(c) The weight of the flask into which the solid has been introduced filled with water up to the mark or completely as before  $W_2$

Then we know that owing to the introduction of the solid into the flask a volume of water has been expelled which is equal to that of the solid introduced, the weight of this volume of water is  $(W_2 + W) - W_1$ , therefore the relative density of the solid is

$$S = \frac{\text{weight of solid}}{\text{weight of equal volume of water}} = \frac{W}{W_2 + W - W_1}$$

The following methods for determining relative densities of solids are based on the principle of Archimedes, according to which a body when immersed in a liquid experiences a loss of weight equal to the weight of the volume of liquid displaced.

(ii.) *The hydrostatic balance*.—The solid is

weighed in air; call this weight  $W$ ; it is then suspended by means of a fine thread from one of the scale pans and weighed again; call this  $W_1$ ; it is then suspended as before, immersed in water and weighed; call this  $W_2$ . Then, by the principle enunciated above, the weight of water displaced by the solid—that is, the weight of a volume of water equal to the volume of the solid immersed—is  $W_1 - W_2$ , and the relative density of the solid is  $S = \frac{W}{W_1 - W_2}$ .

(iii.) *Jolly's balance*.—The principle is the same as that of the hydrostatic balance.

(iv.) *Nicholson's hydrometer*.—This instrument belongs to the class of hydrometers in which the volume immersed is kept constant while the weight is changed. It consists of two cups connected by a fine stem on which is placed the mark of constant immersion. The instrument is placed in a vessel of distilled water of suitable size and the following observations are made:—

(a) Weights,  $W$ , are placed in the upper cup till the instrument sinks to the mark.

(b) The solid, together with sufficient weights,  $W_1$ , to produce the same result, are placed in the upper cup.

(c) The solid is placed in the lower cup, and weights,  $W_2$ , in the upper cup till the instrument sinks to the mark again. From these data we find the relative density  $S = \frac{W - W_2}{W_1 - W_2}$ .

All the methods mentioned must be modified for

1. Porous substances. In order to determine what is termed the *apparent density*, that is, the weight of the apparent volume including air spaces, porous substances pervious to water must be covered with varnish before immersion.

2. Substances soluble in water. It is necessary to substitute for water some liquid of known relative density,  $\rho_1$ , in which the solid will not dissolve. Then if  $\rho$  is the relative density of the solid when referred to the liquid of density  $\rho_1$  as standard, its relative density referred to water is  $\rho \cdot \rho_1$ .

3. Solids lighter than water. (a) A liquid of known density in which the solid will sink is substituted for water. The calculation is the same as above in 2. (b) The solid may be attached to one of known weight,  $w$ , and known relative density,  $\rho_1$ , and of such a volume that the two together will sink. The heavy solid is called a *sinker*; the form it takes must vary according to the light solid, the relative density of which is required. The calculation is simple. Let the weight of the solid in air be  $W$ ; the total loss of weight on immersing sinker plus solid =  $W_1$ ; then weight of water displaced by sinker =  $\frac{w}{\rho_1}$ ; therefore, loss of weight on immersion due to light solid =  $W_1 - w$ .

$$\text{and relative density of light solid} = S = \frac{W}{W_1 - w \cdot \rho_1}$$

(c) The solid may be prevented mechanically from rising; this might be done by having a wire cage attached to the lower pans in a Jolly's balance or in a Nicholson's hydrometer.

**II. RELATIVE DENSITIES OF LIQUIDS.**—The standard is water at the temperature of its maximum density.

1. *Experimental processes based on the determination of the absolute density* are not numerous. Specific gravity bottles which when filled up to a mark in the neck contain a definite volume, generally marked outside, are much in use. The difference between the weight of the bottle when filled with liquid and when empty gives the weight of a known volume of liquid, from which the absolute density, i.e. the weight of unit volume, can be calculated.

2. *Experimental processes based on determining the ratio between a specified mass of the liquid and that of an equal volume of water.*

(i.) *The hydrostatic balance.*—A glass rod is weighed first in air, then immersed in the liquid, and finally immersed in water. If  $W$  and  $W_1$  are the losses of weight on immersion in the liquid and in water respectively, then these are the weights of equal volumes, as both are the weight of a volume of liquid equal to the volume of the rod. Hence the relative density of the liquid is  $S = \frac{W}{W_1}$ .

(ii.) *The specific gravity bottle.*—A glass vessel of suitable size and form is weighed when empty in air—let this be  $W$ ; it is then weighed when filled with water—let this be  $W_1$ ; it is again weighed when filled with the liquid—let this be  $W_2$ ; the relative density is given by

$$\text{the formula } S = \frac{W_2 - W}{W_1 - W}.$$

(iii.) Method based on the fact that when two columns of liquid are in equilibrium with each other their heights are inversely proportional to their densities.—A tube of the shape

shown in the figure is very suitable. There is air between A and B, water between B and F, and the liquid under examination between A and E. The vertical distances A E and B F are measured—let these be  $h$  and  $h'$ ; then  $ph = p'h$ , where  $p$  and  $p'$  are the absolute densities of the two liquids, but  $p = 1$  and  $p' = \frac{h}{h'}$ .

(iv.) *Hydrometers.*—These are of various kinds.

A. The volume immersed is kept constant, and is indicated by a mark on the stem.

The relative density is given by  $S = \frac{G+W}{G+W_1}$ , where  $G$  is the weight of the hydrometer,  $W$  is the weight necessary to make it sink to the mark when immersed in the liquid, and  $W_1$  is the weight required to cause it to sink to the same mark when immersed in water. Nicholson's and Fahrenheit's hydrometers belong to this class.

B. The weight of the hydrometer is kept constant, and the volume immersed varies. A scale is attached to the stem; this is divided differently in different types of instruments.

a. It is divided into equal parts; to find the relative density it is necessary to consult a table in which these arbitrary units are expressed in terms of densities. Beaumé's hydrometer is an instrument belonging to this class.

β. The scale-readings give directly the relative densities sought. In order that this may be done the volumes immersed must decrease in harmonical progression as the densities increase in arithmetical progression. Twaddle's hydrometer belongs to this class. A difference in relative density of 0.005 is taken as one degree, so that there are 200° for a range of relative density between 1 and 2. Hence for a reading of  $n$  Twaddle, the relative density  $S = 1 + \frac{n}{200}$ .

(v.) *Specific gravity balls.*—These are sets of small glass balls with the number indicating a relative density marked on each. The experimental work consists in ascertaining which ball will just float in the liquid. The number on the ball gives directly the relative density of the liquid.

The nature of the liquid, the quantity of it at our disposal, and the degree of accuracy required, must decide to which of the above methods the preference is to be given. For very rapid and only approximate work it is best to use a hydrometer, while the specific gravity bottle, which can be made very small and so as to present a minute surface for evaporation, is best for accurate work as well as for cases in which we have to deal with only a small quantity of liquid or with a very volatile liquid.

**III. RELATIVE DENSITIES OF GASES AND VAPOURS.**—The standard is air at 0° and a pressure of 760 mm. Relative densities are found by determining the absolute density at a known temperature and pressure, and then calculating what that density would be at 0° and 760 mm. pressure, on the assumption of the rigorous truth of Boyle's and Charles's laws. The absolute density of the standard, that is of air, is supposed known; Regnault's value, 0.001293, is generally accepted. It is to be regretted that the word *density* is almost universally used when the *relative density* or the *specific gravity* of a gas or vapour is meant.

A. *Relative densities of gases*, that is, of substances which are gaseous at the ordinary temperature.

1. *Regnault's method.*—The method first used by Biot and Arago<sup>1</sup> was wonderfully improved by Regnault.<sup>2</sup> A large glass balloon is

<sup>1</sup> Biot and Arago, 'Détermination du poids du litre d'air,' *Mémoires de l'Acad. 1806*.

<sup>2</sup> Regnault, 'Détermination de la densité des gaz,' *Mémoires de l'Institut, XXI*.

filled with the gas at pressure  $H$ , and the temperature of melting ice. In order to avoid the very uncertain correction for buoyancy in air, which is of the greatest importance in weighing quantities of gas, which are often lighter than the air displaced, the balloon is weighed when counterbalanced by one of the same volume and made of the same glass. It is then exhausted to pressure  $h$ , the temperature being kept at zero, and weighed again. The difference,  $W$ , between the two weights gives the weight of the gas filling the balloon at pressure  $H-h$ , from which that at normal pressure is deduced to be  $-W_0 = W \cdot \frac{760}{H-h}$ . The volume of the balloon

being known or determined, we possess all the necessary data for calculating the absolute density of the gas. The utmost has been done from the physical side to secure accuracy in these determinations; the great difficulty at present is to obtain the gases used in a state of sufficient chemical purity.

2. *Bunsen's method.*<sup>1</sup>—This is based on the law that the velocity of effusion of gases through fine tubes is inversely proportional to the square roots of their relative densities. This method is applicable when only small quantities of gases are at our disposal, and when only approximate values are required.

B. *Relative densities of vapours*, that is, of substances which must be raised to a temperature above that of the atmosphere, in order to change them into gases.

Here, again, it is the absolute density which is determined directly, and which is referred to that of air. The experimental processes consist either in determining the weight of a known volume of gas (Dumas's method), or in determining the volume occupied by a known weight<sup>2</sup> (Gay-Lussac's, Hofmann's, Moyer's method).

Let  $W$  be the weight of any volume,  $v$ , of any vapour at temperature  $t$  and pressure  $p$ ; let  $W'$  be the weight of an equal volume of air at the same temperature and pressure; then the relative density of the vapour  $d = \frac{W}{W'}$ , but

$$W = v\delta \cdot \frac{1}{1+at} \cdot \frac{p}{760} \cdot d = \frac{W'}{v\delta} \cdot \frac{760}{p} (1+at)$$

where  $\delta$  is the weight of 1 c.c. of air at  $0^\circ$  and 760 mm. According to this formula, in which  $\delta$  and  $a$  are constants, four magnitudes,  $v$ ,  $t$ ,  $p$ , and  $W$ , must be determined in order to give us  $d$ .

*Dumas's method.*—The weight  $w$  of a thin glass balloon ending in a long fine neck, when full of dry air at temperature  $T$  and pressure  $P$ , is determined. Excess of the substance to be vapourised is introduced into the balloon, which is then heated in a bath to a suitable temperature. When vapour ceases to escape from the neck of the balloon, the end of the neck is sealed by melting in the blowpipe; the temperature,  $t$ , of the bath, and the atmospheric pressure,  $p$ , being noted. The weight,  $w_0$ , of the balloon full of vapour is thus determined. By breaking the point of the neck under water or mercury, the balloon is completely filled with one of these liquids, and the difference between

the weight of it when filled and when empty gives the weight of liquid filling it; the absolute density of this liquid being known, we have the data required for calculating the volume of the balloon. We have now obtained  $v$ ,  $t$ , and  $p$  by direct observations. We must find the weight,  $W$ , of vapour filling the balloon at temp.  $t$ , and pressure  $p$ .

$$\begin{aligned} W &= w_0 - \text{weight of glass} \\ &= w_0 - (w - \text{air filling balloon at temp. } T \text{ and pressure } P) \\ &= w_0 - w + w_u \end{aligned}$$

$$\text{where } w_u = v\delta \cdot \frac{1}{1+at} \cdot \frac{P}{760}$$

*Gay-Lussac's method.*<sup>2</sup>—A tube of about half the barometric height, divided into cubic centimetres, and completely filled with mercury, dips into a trough of mercury and is surrounded by a vessel of water. The whole apparatus can be heated to the required temperature. A known weight of the substance contained in a small glass bulb is allowed to rise in the tube filled with mercury. On heating the apparatus the bulb breaks, and the substance is changed to vapour. The four data necessary for substitution in the above formula are obtained in the following way:—

$W$  = the weight of substance, is obtained by direct weighing;

$v$  = the volume, is obtained by reading the volume occupied by the vapour in the tube in terms of scale-divisions;

$t$  = the temperature of the surrounding water;

$p$  is given by the difference (reduced to  $0^\circ$ ) between the height of the barometer and the height of the mercury column in the tube.

*Hofmann's method.*—This method is a modification of that of Gay-Lussac, a tube longer than the barometric height being used. The observations and calculations are the same as in Gay-Lussac's method. This method has the advantage that the substances are volatilised at temperatures lower than their ordinary boiling-points.

*V. Meyer's method.*<sup>3</sup>—A known weight,  $W$ , of substance is dropped into a glass vessel of the form shown in the figure. The bulb of the apparatus is kept at a temperature higher than the boiling-point of the substance. The volume,  $v$ , of the air which escapes through the side tube, and whose place in the tube is taken by an equal volume of vapour, is collected and measured at temp.  $t$  and pressure  $p$ . We have so obtained all the data necessary. This method is very rapid, and it possesses the additional advantage of not requiring a determination of the temperature of the vapour itself, a process which is always attended with great uncertainties.

Corrections to be applied in determinations of relative densities. The relative density being the ratio of two absolute densities, we have to consider the circumstances which produce a change in the absolute density, and how we can introduce suitable corrections. The absolute density being got by dividing the weight by the volume, it is

<sup>1</sup> Bunsen, *Geometrische Methoden*.  
<sup>2</sup> *Q. ANALYSIS*, vol. I. pp. 237-239.

best to consider the corrections to be applied to each of these two quantities separately.

1. *The weight.*—In order to eliminate errors due to the balance we must in all accurate work use the method of double weighing. This gives the true weight in air; the true weight *in vacuo* is given approximately by

$$W = w \left( 1 - \frac{\lambda}{\rho} + \frac{\lambda}{\sigma} \right), \text{ where } w = \text{true weight in air.}$$

$\lambda$  = relative density of air at the moment of weighing. This will depend on, and entail a knowledge of, the temperature, pressure, and hygroscopic condition, of the air.

$\sigma$  = relative density of substance weighed. The approximate value for this obtained by using the uncorrected weight may be used.

$\rho$  = relative density of the weights.

2. *The volume.*—The volume changes with the temperature and with the pressure.

a. *Influence of temperature.*—In nearly all cases the volume increases as the temperature is raised. Hence the absolute density, which varies inversely as the volume, decreases. If the volume  $V_0$  at temperature  $0^\circ$  changes to  $V_t$  at temperature  $t$ , where  $V_t = V_0(1 + \alpha t)$ ,  $\alpha$  being the coefficient of cubical expansion, the density  $D_0$  changes to  $\frac{D_0}{1 + \alpha t}$ .

It is therefore necessary in all accurate density determinations to state the exact temperature at the time of the experiment, and to record the result as relative density at temperature  $t'$ , or if the determination has to be reduced to normal temperature, that is, to the temperature of the standard ( $4^\circ$  when water,  $0^\circ$  when air), it is necessary to calculate what the absolute density at that temperature would be from the above formula, knowing the value for  $\alpha$ .

b. *Influence of pressure.*—The change in volume owing to change in atmospheric pressure is imperceptible in the case of liquids and solids, but it is very large in the case of gases and vapours. Boyle's law gives us the means of calculating what the volume would be at normal pressure, that at any other pressure being known. The volume being inversely proportional to the pressure, the absolute density is directly proportional to the pressure.

Lord Rayleigh has pointed out (*Pr.* 43, 356) that the glass balloon used in Regnault's method for determining the relative densities of gases when exhausted is sensibly compressed by the pressure of the air; hence the *tare* of the balloon is too large because of the lessened buoyancy of the atmosphere, and therefore the weight of the gas when the balloon is filled is too small. A correction must therefore be experimentally made for each balloon used (for method *v.* Lord Rayleigh *l.c.*, also Cooke and Richards, *P. Am. A.* 24, 184).<sup>1</sup>

<sup>1</sup> Dumas' method for determining the relative densities of gases is described in *A. Ch.* [2] 33, 337; Gay-Lussac's in *Blot's Traité de Phys.* 1, 291; Hofmann's in *B.* 1, 198; and Victor Meyer's in *B.* 11, 1868 and 2253. For criticisms on, and modifications of, Meyer's method *v.* *B.* 12, 609, and 1112; 18, 401, 861, 991, 1079, 1135, and 2019; 14, 1797; and 18, 127, 1161, and 2775 (in the last paper by V. Meyer (*B.* 15, 2775) will be found an interesting and valuable criticism of the various methods for finding the rel. densities of gases); *v.* also *B.* 18, 1041; 19, 1461; also *C. J. Trans.* for 1880, 491. Modifications of Dumas's method are described by Bunnen, *v. Chemische Methoden*, 2nd ed. 1877, p. 173; also by Pettersen and Ekstrand, *B.* 13, 1191; and

It remains now to indicate in how far the determination of the density, that is, of one of the physical constants, of various kinds of matter is of importance in those investigations into the constitution and the decompositions of matter with which the chemist is concerned. In these investigations it is often found more convenient to deal with the reciprocal of the density  $\frac{1}{d}$  to which the name of *specific volume* has been given.

Let us first consider those cases in which we are concerned only with the constitution of substances in the state of chemical equilibrium, and not with chemical change.

1. The density being a well-defined physical constant, a determination of its value tells us in many cases whether the substance under examination is or is not approximately pure. It must, however, be borne in mind that in the case of many metallic elements the value of the relative density will depend on the previous treatment the substance has undergone, such as whether it has been hammered or drawn into wire, whether it has been tempered, &c.

2. Many tables have been compiled, in which the percentage of acid or of alkali contained in an aqueous solution of definite relative density is given. By the help of such tables the determination of the relative density enables us at once to estimate quantitatively the acid or alkali present in a known volume of the solution.

3. How the determination of the relative density of a gas or of a vapour gives us the means of calculating its molecular weight will be found described in the article ATOMIC AND MOLECULAR WEIGHTS (vol. i. p. 336).

4. Those elements which exist in allotropic modifications, and those compounds which show polymorphism, differ, though often only slightly, in density. Thus we have

Subphur	Phosphorus
Octahedral . . . . . 2.05	White . . . 1.82
Prismatic . . . . . 1.98	Red . . . 2.2
Amorphous insoluble 1.95	
Carbon	Arsenious oxide
Diamond . . . . . 3.55	Amorphous
Graphite . . . . . 2.3	vitreous 3.7385
Gas carbon . . . . . 1.885	Octahedral 3.695
	Rhombic 3.85
Titanic acid	Calcium carbonate
Rutile . . . . . 4.24	Arragonite 2.94
Brookite . . . . . 4.15	Calcite . 2.72
Anatase . . . . . 3.9	

especially by Pawlowski, *B.* 16, 1293. Thorpe (*C. J. Trans.* for 1880, 147-160) has described a very complete method based on Hofmann's process. V. Meyer (*B.* 9, 1240, and 10, 2008) has described a method based on the displacement of mercury. In *W. A.* 22, 468 and 493, von Klobukow describes two processes for determining vapour densities with great accuracy; one is adapted for bodies with low boiling-points, the other for bodies which boil at high temperatures. La Coste (*B.* 18, 2122) describes a modification of V. Meyer's apparatus whereby the vapour densities of easily decomposable compounds may be determined at low temperatures and under very small pressures. A modification of V. Meyer's apparatus, by which a vapour density and the exact temperature of observation can be simultaneously determined, is described by Nilson and Pettersson in *J. pr.* [2] 83, 1; *v.* also Schall, *B.* 20, 1438. Mühlstedt and Schoop (*Z. F. C.* 1, 169) describe an apparatus for determining vapour densities under small pressures.

*Silica*

Quartz . . . 2.65

Tridymite . . 2.3

(cf. ALLOTROPY, vol. i. p. 128). Little has been done as yet in tracing the connexions between these differences in density and the other physical and chemical properties of these substances, but some interesting facts have been brought to light. Thus we know that long-continued heating changes the relative density of *anatase*, 3.9, and of *brookite*, 4.15, to 4.24, which is the relative density of *rutile*; in the case of silica, and in that of calcium carbonate, the relative density of the heavier variety is changed into that of the lighter variety, by the action of heat. It has also been noticed that in a great many cases the higher relative density belongs to that allotropic modification which contains the less potential energy in so far as there has been production of heat in the change from the less dense to the more dense modification. Thus 80 gram units of heat are produced in the change of 82 grams of prismatic sulphur (rel. dens. 1.98) into octahedral sulphur (rel. dens. 2.05); the change of white phosphorus (rel. dens. 1.82) to red phosphorus (rel. dens. 2.2) is accompanied by the production of about 25,000 thermal units per 31 grams phosphorus changed. However, the case of the change of *aragonite* (rel. dens. 2.94) to *calcite* (rel. dens. 2.72), which is accompanied by the production of 4,000 heat units per 100 grams material changed, as well as other similar cases, prove that this rule is by no means general.<sup>1</sup>

6. It has been observed that on bringing together quantities  $a$  and  $a'$  of two substances of relative density  $d$  and  $d'$ , the resulting density is not given by  $\Delta = \frac{a+a'}{d+d'}$ ; that is the resulting vo-

lume is not the sum of the volumes of the constituents. The following cases have been investigated:—

1. *Solution of a salt in water*.—Contraction generally takes place. From measurements of the amount of contraction, and of the specific heat of the solution, and the coefficient of expansion, Deville has calculated the amount of heat due to the contraction, and has tried to show that in most cases this is sufficient to account for all the thermal phenomena of solution.

It has been observed further that the amount of contraction increases with the quantity of the solvent, approaching a maximum. Also the amount of contraction for the same amount of solvent decreases as the temperature at which solution is effected is raised. The most interesting researches in connexion with this subject are those of Valson,<sup>2</sup> who has endeavoured to show that the contraction produced on dissolving a salt in water is made up of two parts, one of which is a characteristic constant of the basic radicle, and the other is a characteristic constant of the acidic radicle.

II. *Mixture of two liquids*.—A contraction always takes place which varies in magnitude

with the relative quantities of the two liquids used. Here again Deville has tried to explain the thermal effect produced on mixing the two liquids by means of this contraction. The volume-change on mixing alcohol and water is the one which has been most thoroughly studied.

III. *Chemical action between two solutions*.—

The cases studied deal mainly with neutralisation-phenomena. It has been established that the volume-change is expansion if the bases are KOH and NaOH, and contraction if the base is  $\text{NH}_4\text{OH}$ . Here also the volume-change decreases as the temperature is raised. Ostwald, who investigated the density-changes attendant on the neutralisation of dilute aqueous solutions, has arrived at a law the same as that found by Valson for solution. He found the volume-change due to chemical change to be the sum of two constants which belong individually to each of the components, and which do not depend on the substance with which each component combines.

6. A knowledge of the relative density of an element or of a compound is necessary for the determination of the constants;

$$\text{atomic volume} = \left( \frac{\text{atomic weight}}{\text{relative density}} \right)$$

$$\text{and molecular volume} = \left( \frac{\text{molecular weight}}{\text{relative density}} \right).$$

A description of how the atomic volume, regarded as a periodic function of the atomic weight, assists in classifying the elements will be found in the articles CLASSIFICATION, CHEMICAL, and PERIODIC LAW. The generalisations arrived at with regard to molecular volumes of solids, and especially of liquids, will be dealt with in the article, SPECIFIC VOLUMES, in vol. iv.

7. Another physical constant which entails a knowledge of the relative density of a body, and which has led to some valuable generalisations as to the interdependence of chemical constitution and physical properties, is the *refraction equivalent*. This constant is defined as  $\frac{\mu-1}{d}M$ ,

where  $\mu$  is the refractive index,  $M$  the molecular weight, and  $d$  the relative density, of the substance under examination. On this subject v. PHYSICAL METHODS USED IN CHEMISTRY.

The cases in which a knowledge of the relative density has been employed in the solution of problems belonging to chemical kinetics are but few.

1. The change in the relative density of vapours and gases (calculated to normal temperature and pressure) under different temperatures and pressures has been utilised to trace the rate of decomposition relatively to the change of temperature or pressure (v. DISSOCIATION).

2. From a knowledge of the volume-change produced on neutralising a base A by an acid B, and on neutralising A by another acid C, as well as from knowing the specific volume of a solution containing A, B, and C, in equivalent quantities, Ostwald deduced the chemical composition of this solution, that is, he determined the ratio between the quantities present of AB and AC. The knowledge of this ratio enabled him to calculate the coefficients of relative affinity of the acids B and C (v. AFFINITY, vol. i. p. 75).

<sup>1</sup> St. Claire Deville, *Sur la Contraction et la Chaleur de Contraction* (C. R. 60).

<sup>2</sup> Valson, *Propriétés moléculaires des solutions salines au point de vue des densités* (C. R. 62).

8. In his researches on the velocity of chemical changes dependent on the varying conditions of the experiment, van 't Hoff' investigated the velocity of the change of rhombic sulphur into monosymmetric by observing the increase in volume at fixed intervals of time. The increase in volume being due to the change of rhombohedral sulphur of relative density 2.05 into oblique sulphur of relative density 1.98. I. F.

**DEOXIDATION.** This term was originally used to denote any process wherein oxygen was removed, wholly or in part, from a compound. Thus the formation of  $\text{KClO}_3$  by heating  $\text{KClO}_4$ ,

several classes of compounds to produce less oxidised bodies is called a *deoxidising agent* or *reducing agent*; while any element or compound which generally reacts to form bodies more oxidised than the original substances is called an *oxidising agent* or *oxidiser*. Probably every element and compound takes part in some chemical changes in which it acts either as an oxidiser or a deoxidiser; but these terms are generally confined to such elements and compounds as frequently react in the way indicated by the names. The following equations exhibit some common cases of deoxidation:—

Original element or compound	Deoxidiser	Deoxidised product	Oxidised product
$\text{O}_2$	$+ 2\text{H}_2$	$= 2\text{H}_2\text{O}$	$+ (2\text{H}_2\text{O})$
(in this case the water may be regarded as produced either by the oxidation of hydrogen or by the reduction of oxygen)			
$\text{Cl}_2$	$+ \text{H}_2$	$= 2\text{HCl}$	$+ (2\text{HCl})$
$\text{O}_3$	$+ \text{Hg}$	$= \text{O}_2$	$+ \text{HgO}$
(in this case the ozone is reduced to oxygen)			
$2\text{Cl}_2$	$+ 2\text{HgO}$	$= \text{Hg}_2\text{OCl}_2$	$+ \text{Cl}_2\text{O}$
$\text{Cl}_2$	$+ \text{K}_2\text{FeCy}_6$	$= \text{KCl}$	$+ \text{K}_2\text{FeCy}_6$
$2\text{HNO}_3$	$+ \text{Sn}$	$= \text{N}_2\text{O}_3$	$+ \text{SnO}_2 + \text{H}_2\text{O}$
$2\text{KClO}_3$	$+ 3\text{C}$	$= 2\text{KCl}$	$+ 3\text{CO}_2$
$\text{Fe}_2\text{O}_3$	$+ 3\text{H}_2$	$= 2\text{Fe}$	$+ 3\text{H}_2\text{O}$
$\text{CuO}$	$+ \text{CO}$	$= \text{Cu}$	$+ \text{CO}_2$
$\text{BeCl}_2$	$+ \text{Na}$	$= \text{Be}$	$+ 2\text{NaCl}$
$\text{Fe}_2(\text{SO}_4)_3\text{Aq}$	$+ \text{SO}_2$	$= 2\text{FeSO}_4\text{Aq}$	$+ 2\text{SO}_3\text{Aq}$
$2\text{FeCl}_3\text{Aq}$	$+ \text{Zn}$	$= 2\text{FeCl}_2\text{Aq}$	$+ \text{ZnCl}_2\text{Aq}$
$\text{H}_2\text{O}_2\text{Aq}$	$+ \text{HNO}_2\text{Aq}$	$= \text{H}_2\text{O}$	$+ \text{HNO}_3\text{Aq}$
$2\text{HgCl}_2\text{Aq}$	$+ \text{SnCl}_2\text{Aq}$	$= 2\text{HgCl}$	$+ \text{SnCl}_4\text{Aq}$
$\text{HgCl}_2\text{Aq}$	$+ \text{SnCl}_4\text{Aq}$	$= \text{Hg}$	$+ \text{SnCl}_4\text{Aq}$
$2\text{AgNO}_3\text{Aq} + \text{H}_2\text{O}$	$+ \text{C}_2\text{H}_5\text{O}$	$= 2\text{Ag}$	$+ \text{C}_2\text{H}_5\text{O}_2 + 2\text{HNO}_3\text{Aq}$
$\text{K}_2\text{MnO}_4\text{Aq}$	$+ 3\text{H}_2\text{C}_2\text{O}_4\text{Aq}$	$= \text{K}_2\text{O}_4\text{Aq} + 2\text{MnO}_2$	$+ 3\text{H}_2\text{O} + 6\text{CO}_2$
$\text{FeCl}_3\text{Aq}$	$+ \text{KI}\text{Aq}$	$= \text{FeCl}_2\text{Aq} + \text{I}$	$+ \text{KClAq}$

as well as that of  $\text{KCl}$  by heating  $\text{KClO}_4$ , are alike deoxidations; similarly the production of  $\text{Cr}_2\text{O}_3$  from  $\text{CrO}_3$  by the action of alcohol, and the formation of  $\text{Cr}$  by heating  $\text{Cr}_2\text{O}_3$  with carbon, are deoxidations. But as the term *oxidation* (*q. v.*) has been widened to include those chemical reactions wherein the negative or acidic radicle of a compound is increased relatively to the rest of the body, and also those wherein an element combines with a more negative element, or with a radicle more negative than itself, so has the term deoxidation been extended until it is now generally applied to all processes which result in the withdrawal of the whole or a part of the negative radicle of a compound.

The terms *deoxidation* and *reduction* are practically synonymous; the latter is more commonly used than the former.

As thus employed the terms deoxidation and oxidation are correlative; the deoxidation of one body is accompanied by the oxidation of another. Thus, to take a very simple case, when hydrogen is burnt in oxygen with production of water, the hydrogen is oxidised and the oxygen may be said to be deoxidised. If the reaction is represented in molecular formulae the processes of oxidation and deoxidation are made apparent;  $2\text{HH} + \text{OO} = 2\text{H}_2\text{O}$ . Similarly, when hydrogen and chlorine combine,  $\text{HH} + \text{ClCl} = 2\text{HCl}$ , the hydrogen is oxidised while the chlorine is deoxidised or reduced.

Any element or compound which reacts with

*Études de Dynamique Chimique.*

Among the substances commonly used in the laboratory to accomplish deoxidations, hydrogen, carbon, carbon monoxide, sulphur dioxide, nitrous acid or a nitrite, stannous chloride, and aldehyde are prominent. The conditions under which deoxidations occur vary much; thus,  $\text{HgCl}_2\text{Aq}$  is almost instantly reduced by  $\text{SnCl}_2$  at the ordinary temperature; to reduce  $\text{Fe}_2(\text{SO}_4)_3\text{Aq}$  completely to  $\text{FeSO}_4$  by  $\text{SO}_2$ , the gas must be passed into the liquid for a long time, even when the liquid is kept hot;  $\text{K}_2\text{MnO}_4\text{Aq}$  is reduced by  $\text{H}_2\text{C}_2\text{O}_4\text{Aq}$  rapidly if the liquid is warm and contains sufficient  $\text{H}_2\text{SO}_4$  to dissolve the  $\text{MnO}_2$  produced; to effect the complete reduction of  $\text{FeCl}_3\text{Aq}$  by  $\text{KI}$  the liquid must be slightly acid, and the reaction should proceed for some time at a fairly high temperature and under increased pressure;  $\text{Fe}_2\text{O}_3$  is deoxidised by  $\text{H}$  when a stream of the gas is passed over the heated oxide; to reduce  $\text{BeCl}_2$  by  $\text{Na}$  the chloride must be kept molten (*cf.* articles COMBUSTION, OXIDATION, REDUCTION).

DEOXYBENZOIN v. PHENYL BENZYL KETONE.

DEOXY-BENZOIN-ACETIC ACID v. PHENYL-BENZYL-PROPIONIC ACID.

DEOXY-BENZOIN CARBOXYLIC ACID v. PHENYL BENZYL KETONE CARBOXYLIC ACID.

Anhydride v. BENZYLIDENE-PHTHALIDE.

**DESMOTROPY.** A term given to the breaking up of the 'double bonds' in the benzene ring. Thus phloroglucin forms a penta-ethyl derivative in which the five ethyl groups are

directly united to ring carbon atoms. The constitution of this body, according to Herzig a.

**DESOXALIC ACID**  $\text{C}_6\text{H}_8\text{O}_4$ , i.e.  $\text{CO}_2\text{H.CH(OH).C(OH)(CO}_2\text{H)}_2$ . *Carboxy-racemic acid*. Its ether is formed, together with a syrupy isomeride (Brunner, B. 12, 542) and other products, by the action of 8 p.c. sodium-amalgam on cold oxalic ether. After saponification by KOH the free acid is obtained by exactly neutralising the Ba salt by  $\text{H}_2\text{SO}_4$  and evaporating at  $45^\circ$  (Löwig, J. pr. 79, 455; 83, 139; 84, 1; Klein, J. pr. [2] 20, 146).

*Properties*.—Hygroscopic crystalline mass (containing aq.). V. e. sol. water and alcohol. Decomposed by heat. Its solution evolves  $\text{CO}_2$  on evaporating above  $50^\circ$ , leaving racemic acid.

*Salts*.— $\text{Na}_2\text{A}^{'''}$ .— $\text{K}_2\text{HA}^{''}$ . S. 5.2 at  $16^\circ$ : crystalline crusts.  $\text{K}_2\text{A}^{'''}$ , gummy.  $\text{Ba}_2\text{A}^{''}$ , 2aq.  $\text{Ca}_2\text{A}^{''}$ , 8aq.  $\text{Pb}_2\text{A}^{''}$ , 2O.  $\text{Ag}_2\text{A}^{''}$ .

*Ethyl ether Et.A}^{'''}, [85°]. S. 10 at  $16^\circ$ . Triclinic crystals,  $a:b:c=422:1:757$ ;  $\alpha=84^\circ 27'$ ,  $\beta=90^\circ 82'$ ,  $\gamma=90^\circ 6'$ .*

*Acetyl derivatives*  $\text{C}_6\text{H}_7\text{AcO}_4$ , and  $\text{C}_6\text{H}_7\text{Ac}_2\text{O}_4$ , are non-hygroscopic oils, not decomposed at  $120^\circ$ .

*Benzoyl derivatives*  $\text{C}_6\text{H}_7\text{BzO}_4$ , and  $\text{C}_6\text{H}_7\text{Bz}_2\text{O}_4$ , are oils, not decomposed at  $140^\circ$ .

*Amide*. Amorphous (Brunner).

**DESOXY-AMALIC ACID** v. AMALIC ACID.

**DESOXY-BENZOLIN** v. PHENYL BENZYL KETONE.

**DESOXY-CHOLIC ACID** v. CHOLIC ACID.

**DESOXY-CODEINE** v. CODEINE.

**DESOXY-CUMINOIN** v. CUMINOIN.

**DEUTERO-ALBUMOSE** v. PROTEIDS.

**DEXTRENE**  $\text{C}_6\text{H}_{10}\text{O}_5$  (at  $130^\circ$ ).  $[\alpha]_D=223^\circ$ .

A gummy substance occurring in unripe beet-root (Scheibler, J. T. C. 1875, 790). Formed also in the lactic fermentation of sugar (Tiegchem, Jahres. d. Agriculturchemie, 1879, 544). Amorphous; v. sol. water, forming a sticky liquid. Inspid taste. Its conc. aqueous solution is ppd. by lead subacetate, and gives with Fehling's solution a light-blue sticky pp., no reduction taking place. Boiling dilute  $\text{H}_2\text{SO}_4$  converts it into glucose.  $\text{HNO}_3$  gives oxalic acid only. Iodine gives no colouration.

*Animal dextrane*  $\text{C}_6\text{H}_{10}\text{O}_5$ .  $[\alpha]_D=157^\circ$ . Secreted by *Schizoneura lanuginosa*, a louse that forms galls on elm trees. Amorphous. Sl. sol. cold, more sol. boiling, water, insol. alcohol and ether. Fehling's solution gives a gelatinous coagulum, without reduction. Iodine gives no colour. Boiling dilute  $\text{H}_2\text{SO}_4$  gives a substance that reduces Fehling's solution (L. Liebermann, Pf. 40, 454).

**Dextrin**  $\text{nC}_6\text{H}_{10}\text{O}_5$ . Although this term has been in use for a long time, and a correct percentage composition stated for the body it represents, it is only recently that its characters have been more accurately defined, and a place given to it among chemical compounds. Most of the substances to which the term has hitherto been given have many properties in common with dextrin, but it is evident that many of these hold no relation to it, and many more of them are impure conditions of it.

*Occurrence*.—(a) Dextrin is said to be present

in the sap of plants and in most seeds. The evidence of this is, however, altogether unsatisfactory, other bodies possessing some of its properties being in most cases mistaken for it.—

(b) It is a constituent of the juice of horse-flesh (Limpricht, J. 1855, 673), and it is probable, though not proved, that the body therein found is true dextrin.—(c) Reichardt (Ar. Ph. [3] 5, 502) states that the urine of diabetic patients, under certain conditions, contains dextrin; but from his description it is impossible to say whether the body he had under observation was dextrin or not.—(d) Dried starch, heated to  $210^\circ$  and maintained at that temperature for some time, yields a product known as British gum or commercial dextrin.—(e) By moistening the starch with dilute nitric acid, and drying before heating, this conversion is expedited.—(f) Digestion with dilute acids, inorganic and organic, converts starch into dextrin and other bodies. The commercial products from these sources contain dextrin or dextrans, but there are no analyses of them to show what dextrans they contain. For the action of heat and acids on starch see Biot and Persoz, A. Ch. [2] 52, 72; Payen, *ibid.* 55, 225; 61, 372; 65, 225, 334; Guérin-Varray, *ibid.* 60, 68; Jacquelin, *ibid.* [3] 8, 225; Béchamp, C. R. 51, 256; Anthon, D. P. J. 218, 182; 219, 457; O'Sullivan, C. J. 25, 581.—(g) When starch paste is submitted to the action of the unorganised ferment found in germinated grain, and known as diastase, dextrans, among other substances, are produced. It is one of the bodies derived from this source upon which we shall look as a chemical entity, and describe as dextrin; and it is only in as far as the bodies hitherto called dextrin, and obtained from the various sources above mentioned, agree in properties with those we shall find this to possess that we can consider them dextrin.—(h) Dextrin is found in beer, and is probably present in bread, being the product of the action of diastase on starch.—(i) Cellulose is converted into dextrin by the action of sulphuric acid (Branomot, A. Ch. 12, 172), but the identity of the body thus produced is not established.—(j) Dextrose is said to be converted into dextrin (Musculus, Bl. [2] 18, 66) by submitting the sulpho-glucosic acid to the action of spirit containing 95 p.c. alcohol. This, from its optical activity, is not pure dextrin.

*Preparation*.—100 grams of carefully purified potato starch (any other starch would answer, but this is most easily manipulated) are stirred up with 200 c.c. of water at  $55^\circ$ – $60^\circ$ , and as soon as the granules are thoroughly dispersed through the liquid 400 to 500 c.c. of boiling water are added with continual stirring. In this way an almost transparent and perfectly homogeneous paste is obtained. This is cooled to  $63^\circ$ , and a solution containing, in 50 c.c., 1 to 1.5 grams diastase,<sup>1</sup> or its equivalent in cold malt-extract added to it, and the mixture maintained at  $60^\circ$ – $63^\circ$  until the filtrate from a portion cooled no longer gives a colouration with iodine, and it is

<sup>1</sup> It is impossible to state an exact quantity of the preparation of diastase or of cold malt-extract, because the activity of the extract from a definite quantity of malt, and of the preparation of diastase, varies very considerably. A few experiments will, however, be sufficient to determine the quantity of either necessary to transform starch paste into products having an optical activity  $[\alpha]_D=177^\circ$ .

found that the optical activity of the solid matter in solution (v. SACCHARIMETRY) is  $[\alpha]_D = -176.6^\circ$  (O'Sullivan, *J. C.* [2] 17, 125),  $166.7^\circ$  (Brown a. Morris, *ibid.* 47, 527). If the diastase is fairly active, and the proportion above given employed, this point is reached in five minutes' digestion or less; but inasmuch as, if the diastase is not very active, no further conversion to any extent takes place in a moderate time, the digestion may be continued for 15 or 30 minutes without any injurious effect. The solution is then cooled and filtered, to remove a slight turbidity due to a little flocculent matter from the diastase and impurity from the starch or undissolved, because ungelatinised, starch. The filtrate is then quickly boiled and evaporated, best under diminished pressure in a vacuum vessel, to about 200 c.c., and alcohol (S.G. 83) added until a precipitate begins to form; a little more alcohol is added, and the mixture allowed to stand until the syrupy layer collects at the bottom. The clear supernatant liquid is decanted off, and the syrup washed with alcohol. This is dextrin more or less contaminated with maltose and a constituent of the diastase; the former can be completely, but with difficulty, separated by repeatedly dissolving in water, and carefully precipitating with alcohol in the least possible excess, until a portion of the precipitate, dissolved in water, no longer gives a reaction when boiled for three or four minutes with Fehling's solution. The diastase bodies are separated also with difficulty: the precipitate, freed from maltose, is dissolved in a little water and alcohol gradually added, until 5 to 10 p.c. of the whole is precipitated, pure dextrin remains in the supernatant liquid, and is precipitated from it by strong alcohol. To obtain it in the dry state the precipitate is treated with absolute alcohol, which extracts water from it, and renders it capable of being rubbed down to a white hygroscopic powder. The dextrin thus dried retains alcohol with much pertinacity, and if it be required to obtain a preparation absolutely free from that body, the powder must be dissolved in a little water, and boiled in a vacuum vessel until all alcohol is eliminated, and the solution reduced to a thick syrup. It is then transferred, in small quantities at a time, to an evaporating dish, and, while hot, placed under the bell glass of an air-pump over sulphuric acid and the air pumped out. If the syrup was sufficiently thick it swells up and blows out from loss of water. When this cools it becomes a porous, brittle, glassy mass, which can be rubbed down to a white powder if allowed to stand over sulphuric acid for a day or two, or in a few hours if the temperature of the dish be maintained by a steam coil in the air-pump receiver. Brown and Morris, acting on a suggestion of Wiley (*C. N.* 46, 175), propose to remove the last traces of maltose by treating a solution of the impure dextrin with a slight excess of a solution containing equal weights of mercuric cyanide and caustic soda until no further reduction takes place. This product would have to be purified from the materials employed, from the decomposition products, &c. This could probably be accomplished by neutralising with hydrochloric acid, evaporating to a syrup in a vacuum vessel, and submitting to dialysis, precipitating the dextrin in the concentrated

solution with alcohol, and further purifying by partial precipitation with some reagent until the optical activity of the chief product becomes constant.

**Properties.**—Dextrin is uncrystallisable; dried as described above, it is a glassy, colourless body, capable of being rubbed down to a white powder. It is without marked taste, and is colourless. Its solutions are neutral. It is easily soluble in water, and solutions containing as much as 80 p.c. of the body, although syrupy, are thin-fluid. It is slightly soluble in dilute spirit, but insoluble in spirit containing 60 p.c. alcohol. It is not coloured by iodine. Exposed to moist air, and then allowed to stand over sulphuric acid, its weight becomes constant, when it contains from 9.5 to 10 p.c. water. This is almost completely lost in a vacuum over sulphuric acid, and completely in a current of dry air at  $100^\circ$ . The quantity of water corresponds to the formula  $n(C_{12}H_{20}O_{10} \cdot 2OH_2)$ , and the amount of carbon and hydrogen yielded by the dry body agree well with the formula  $C_{12}H_{20}O_{10}$ . It is not precipitated by lime or baryta water, but it forms compounds with those earths which are insoluble in alcohol. It is precipitated by ammoniacal lead acetate, but not by the neutral or basic salt alone. Dilute sulphuric acid converts dextrin into maltose, and thence into dextrose, according to the equations  $C_{12}H_{20}O_{10} + OH_2 = C_{12}H_{22}O_{11}$ , and  $C_{12}H_{22}O_{11} + OH_2 = 2C_6H_{12}O_6$ . The phases of this reaction have as yet not been fully worked out. Diastase converts it slowly into maltose. Nitric acid converts dextrin into saccharic and oxalic acids. With a mixture of nitric and sulphuric acids it yields a nitrate,  $C_{12}H_{17}(NO_3)_2O_9$ , dinitrate according to Béchamp. By dissolving dextrin in acetic anhydride, and heating to  $160^\circ$ , triacetyl dextrin is produced (Schützenberger a. Naudin, *C. R.* 68, 814), but these substitution products require further investigation. A solution of 10 grams dry dextrin in 100 c.c.—a vessel holding exactly 100 grams water at  $15.5^\circ$ —has a S.G. 1.0896, and its apparent optical activity is  $[\alpha]_D = 222$ ,  $[\alpha]_D = 200.4$ . These are good working factors; but a careful and accurate determination of them is yet required. Under the influence of ordinary saccharomyces it is not converted into alcohol (fermented) in a moderate time; in presence of active diastase and this organism it ferments easily. Besides the dextrin here described, there are other dextrans to be found amongst the products of the action of diastase and of acids upon starch (v. STARCH), but experimenters with these bodies are not yet agreed as to their number or properties. Most of the properties just described are common to all the dextrans; but the distinguishing character of the dextrin of which we write is the action of diastase upon it. When a solution containing dextrin and diastase, in the proportion of 1 of the latter to 100 of the former, is digested at  $60^\circ$ – $63^\circ$  no more maltose is formed in the first five minutes than in the second five, in proportion to the amount of dextrin in solution, the conversion being a very slow and gradual process.

It may be fairly said that the opinions of Bondouneau (*C. R.* 81, 972, 1210) and those of Musculus and Gruber (*Bt.* 30, 54) have been shown to be untenable. The former describes three dextrans with different optical activities

and powers of reducing copper oxide; the latter mentions *three* not coloured by iodine, of different optical activity, two having the same reducing power, and the third a higher power. O'Sullivan (C. J. 85, 770) isolated and described *three*, and indicated the existence of a fourth dextrin, all possessing the same optical activity as that given above, and being without reducing action on alkaline copper solution. Brown and Heron (C. J. 85, 596) and Brown and Morris (ib. 47, 527) maintain the evidence of eight dextrins without isolating any of them, but confirm O'Sullivan's observations that all the dextrins have the same optical activity  $\alpha_D = 222$ , and that they are without action on alkaline copper solution. The  $\beta$ -dextrin-iii of O'Sullivan, and the final dextrin of Brown and Morris, agree in properties; it is the dextrin described. All the dextrins are white, glassy, friable bodies, v. sol. water, and insol. strong alcohol. O'Sullivan characterises the dextrins as follows:—*a*-dextrin, coloured by iodine reddish-brown, unacted upon, or but slightly, by diastase at  $64^\circ$ – $70^\circ$ ; at  $66^\circ$ – $67^\circ$ , 17.4 p.c., on transformed products, of maltose is produced in four to ten minutes, there being no increase in the next two hours if the diastase is not in excess and the temperature maintained; at  $65^\circ$ – $66^\circ$ , 34.5 p.c. maltose is formed; at  $63^\circ$ – $64^\circ$ , 51.2 p.c.; and below  $62^\circ$ , 67.8 p.c. This would indicate the molecule of this dextrin to be at least  $C_{17}H_{30}O_{30}$ .  $\beta$ -dextrin, not coloured by iodine.  $\beta$ -dextrin-i is not acted upon, or but slightly, by diastase at  $66^\circ$ ; at  $63^\circ$ – $64^\circ$  it yields in five or ten minutes 34.0 p.c. maltose; at  $61^\circ$ – $62^\circ$  the same quantity is observed, and at  $58^\circ$ – $59^\circ$  there is no increase in the yield; this would indicate the molecule of this dextrin to be at least  $C_{17}H_{30}O_{30}$ . According to Brown and Morris (l.c.) there are eight dextrins, beginning with  $C_{108}H_{180}O_{300}$ , each differing from the one below it by the group  $C_{17}H_{30}O_{30}$ , but they do not appear to have prepared any one of the bodies in a pure state. They determine the position in the series of an unknown one of them by the amount of maltose that it is capable of yielding when acted upon by diastase at  $60^\circ$  (C. J. 47, 543). All the high dextrins are acted upon in a fermenting solution, and yield maltose, and thence alcohol, the lowest dextrin being left. Although the researches referred to herein have thrown much light on the nature and character of the dextrin bodies, much still remains to be done before we can consider our knowledge complete.

*Estimation.*—In substances from which dextrin has not hitherto been isolated, and in which its presence is suspected from the optical activity of their solution, or the nature of their source, before any attempt at estimation is made, it would be necessary to prove its presence by eliminating the bodies with which it may be accompanied by processes indicated above, and comparing the properties of the body isolated with those herein given for dextrin. The estimation may then be effected after the manner indicated below, attention being given to the nature of the bodies with which it may be accompanied. In products in which the presence of dextrin is well established, viz. the various commercial sugars obtained by the action of acids on starch, malt-extract, beer, and such

products, dextrin is estimated as follows:—*I* the commercial starch sugars a known weight of the sugar (15 g. or thereabouts is a suitable quantity) is dissolved in a small quantity of boiling water, the solution cooled and then made up to 100 c.c. This is submitted to fermentation with 0.5 g. yeast, and the fermentation pushed as far as possible. The alcohol is eliminated by distillation, the residue filtered and made up to 100 cc. with the washings; of this an optical activity is taken and  $K$  determined (v. SACCHARIMETRY); if the latter indicates more than 15 p.c. calculated on the solid matter unfermented, the solution must again be submitted to fermentation, and the amount of reducing sugar further diminished; if less, the reducing body may be taken as maltose, and the calculation made accordingly.

*Example.*—15 g. glucose syrup dissolved to 100 c.c., submitted to fermentation with 0.5 g. yeast, yielded 100 c.c. of residue of S.G. 1.0012 = about 3.038 g. solid matter per 100 c.c. 18.57 g. of this solution yielded 0.087 g. CuO; this corresponds to  $0.087 \times 7256 = 0.631$  g. maltose, and to a total amount of maltose in the 100 c.c. of  $100.12 \times 0.631 = 3402$  g., or to  $0.87 \times 4535 = 3934$  g. dextrose, giving a total amount of dextrose in the 100 c.c. of  $\frac{100.12 \times 0.934}{18.57} = 2124$  g.

This is less than 15 p.c. on the solid matter in solution, hence the reduction found above is taken as maltose. The optical activity of the solution was 26.5 divisions of a Soleil-Ventzke-Scheibler saccharimeter; this corresponds to  $26.5 - 34 \times 8.02 = 2.143$  dextrin, and as the solid

matter was found to be 82.0 p.c. of the syrup the dextrin is 17.4 p.c. of the solid matter. In beer the estimation is made in the same way, only, as a rule, in a beer of any age the cupric oxide reduced may be calculated as maltose without further consideration, a correction of .0008 g. being subtracted from the weight of CuO for every gram of beer taken for the reduction. In malt-extract the estimation is effected in the same manner as described for sugar syrup above, the procedure after fermentation being the same as followed in the case of beer. Should active diastase be present in the malt-extract, as is usually the case in the best preparations, the solution should be boiled before fermentation. According to Wiley (C. N. 46, 175) dextrin can be estimated in the starch products by eliminating the reducing bodies by alkaline solution of mercury dicyanide. He proceeds as follows:—The mercury solution is made by dissolving 120 g. HgCy, and 120 g. NaOH in water, and making up to 1 litre. 1 g. of the sugar to be examined is dissolved in 10 c.c.; this is boiled for two or three minutes with an excess of the mercury solution, of which 25 c.c. will as a rule be found sufficient. The solution is cooled, neutralised with HCl, and the bulk made up to 50 c.c. An observation of the optical activity of this solution gives the dextrin. For example, the optical activity of a solution, prepared as described, and observed in a 200 mm. tube, was found to be 2.3 divisions of a S.V.S.

<sup>1</sup> CuO  $\times$  0.7256 = maltose corresponding to CuO.

saccharimeter— $2.3 + 11.56 = 20$  g. dextrin in 100 c.c., i.e. 1 g. in 50 c.c. 1 g. sugar yields 1 g. dextrin or 10 p.p. (Further on this subject v. SACCHARIMETRY.) If any of the higher dextrans should be present the quantity could be approximately estimated by the action of malt-extract at the various temperatures indicated above, and the position and approximate quantity of the dextrin inferred from the amount of maltose formed in five to ten minutes. C. O'S.

**DEXTRO-** Compounds beginning with this prefix, indicating a right-handed rotatory effect on light, are described under the remaining part of the name; e.g. dextro-tartaric acid under TARTARIC ACID.

**DEXTRONIC ACID** v. GLUCONIC ACID.

**DEXTROSE** v. SUGARS.

**DI-** When this prefix is used in a numerical sense it is entirely left out of account in determining the alphabetical position assigned to a compound in this dictionary.

**DIALURIC ACID**  $C_4H_4N_2O_4$ , i.e.

**Formation.**—1. By passing  $H_2S$  through a boiling aqueous solution of alloxan (Liebig a. Wöhler, A. 26, 276).—2. By treating alloxan with zinc and  $HCl$ .—3. By dissolving uric acid in dilute  $HNO_3$  and adding ammonium sulphide. 4. By treating an aqueous solution of alloxan with ammonium or potassium cyanide (Strecker, A. 113, 49).—5. By treating alloxantin with sodium amalgam (Baeyer, A. 127, 12).—6. By treating di-bromo-barbituric acid with  $H_2S$  (Baeyer, A. 130, 133).

**Properties.**—Needles, sl. sol. water, acid to litmus. Oxidised by moist air to alloxantin. Combines with alloxan forming alloxantin. Heated with glycerin at  $100^\circ$  it forms hydurilic acid.

**Salts.**— $NH_4A'$ : silky needles; converted at  $100^\circ$  into blood-red murexide.— $KA'$  (cf. Men-schutkin, A. 182, 70). Urea dialurate  $CON_2H_2C_4H_4N_2O_4$ : stellate crystals (Mulder, B. 6, 1010).

**Iso-tartronyl urea.** Formed by the action of bromine water on isobarbituric acid, amidouracil, or hydroxanthine (Behrend a. Roosen, B. 21, 1000). Prisms (containing 2aq). V. sol. water. Stable towards oxidising agents. Is converted by warming with urea and conc.  $H_2SO_4$  into what is believed to be uric acid.

**DIALYSIS.** The separation of certain substances by liquid diffusion; v. DIFFUSION and PHYSICAL METHODS, vol. iv. p. 172.

**DIAMOND** v. CARBON, vol. i. pp. 685, 686, 687.

**DIASTASE** C 44-33, H 6-93, N 8-92, S 1-07, O 82-91, ash 4-79. The substance that enables malt to convert starch into dextrin and sugar. Green barley malt is digested with dilute alcohol (20 p.c.) for 24 hours; the extract is ppd. with  $2\frac{1}{2}$  vols. absolute alcohol, and the pp. washed with alcohol and ether (O'Sullivan, C. J. 45, 2; Lintner, J. pr. [2] 84, 886; 86, 481).

**Purification.**—Cannot be purified by pp.

with basic lead acetate (L.); purified by repeated solution in water and ppn. with alcohol; the ash can be reduced by dialysis to less than 5 p.p. consisting of calcium phosphate.

**Properties.**—Amorphous; has not been obtained pure. Its action on starch is prevented by strong acids or alkalis, by salts of Cu, Hg, and Ag, by alum, and by  $FeCl_3$ , but not by phenol. Hydroxylamine, formic aldehyde, and nitrous acid at  $40^\circ$  render diastase inactive (Loew, J. pr. [2] 37, 101). Presence of  $CO_2$  accelerates the power of diastase to convert starch into sugar (Baswitz, B. 11, 1443). Above  $63^\circ$  the fermenting power is weakened.

**Reactions.**—1. Does not reduce Fehling's solution even after boiling with  $HCl$ .—2. Does not give a violet colour with  $CuSO_4$  and  $KOH$ .—3. Ppd. by boiling.—4.  $HCl$  gives a pp., sol.  $NaOH$ .—5.  $HOAc$  a pp. sol. excess.—6.  $HgCl_2$  a pp.—7. Basic lead acetate a pp.—8.  $HOAc$  and  $K_2FeCy_6$  a pp.—9. Millon's reagent gives albumen reaction.—10. Warmed with fuming  $HCl$  a violet colour.—11. Guaiacum tincture mixed with a little  $H_2O_2$  gives a blue colour.

V. ALSO FERMENTATION, DEXTRIN, STARCH, and SUGARS.

**Diastase of Kōji.** Kōji is used in Japan to make beer. It is formed by steaming rice-grains and leaving them till a fungus grows on them. An aqueous infusion of this Kōji acts somewhat like malt-extract, for it inverts cane-sugar and hydrates maltose and dextrin, and it liquefies starch paste, forming first maltose and dextrin, then glucose and dextrin (R. W. Atkinson, Pr. 31, 523; 32, 299). The diastase-like ferment is obtained from the albuminous matters in the rice through changes produced by the growth of the fungus.

**DIATERBIC ACID** v. TEREBIC ACID.

**DIATERBILENIC ACID** v. TEREBILENIC ACID.

**DIATERPENYLIC ACID** v. TERPENTLIC ACID.

**DICHRÖINS.** A name given by Brunner and Chuit (B. 21, 249) to the fluorescent colouring matters obtained in Liebermann's reaction by treatment of phenols with conc.  $H_2SO_4$  and nitrous acid. They are obtained by the action of  $H_2SO_4$  saturated with nitrous acid on par-nitrosophenols; but only those polyhydric phenols having the hydroxyl-groups in the meta-positions to one another yield dichroins. The dichroins are divided into (a)-dichroins containing the complex  $C_6N:(O.C_6)_2$  and (β)-dichroins with the group  $C_6N < \begin{array}{c} O \\ \diagup \quad \diagdown \end{array} C_6$ . The colouring matters  $C_{18}H_{11}NO$  from phenol,  $C_{18}H_{11}NO_2$  and  $C_{18}H_{11}N_2O_2$  from resorcin, and  $C_{18}H_{11}NO_2$  from orcin belong to the (a)-group, whilst the (β)-group includes  $C_{18}H_{11}NO_2$  from orcin, azoresorcin, azoresorufin, and azoresorufin ether; the last three are re-

spectively ( $\beta$ )-resorcin-, di-( $\beta$ )-resorcin-, and tetra-( $\beta$ )-resorcin-dichroin (H. Brunner and P. Chuit, B. 21, 2479).

**Chroins.**—Chroins are colouring matters resulting from the action of  $H_2SO_4$  containing nitrous acid on nitroso-phenols, which are analogous to the quinonoximes, and they appear to contain the  $(C_6)_2N-O-N(C_6)_2$ .

**Oxychroins.**—Oxychroins are bodies bearing a similar relation to nitro-phenols as dichroins do to nitroso-phenols. They are obtained in most reactions along with the dichroins during the preparation of the latter. They are richer in oxygen than dichroins and do not fluoresce.

**DICHROISM.** The property exhibited by many doubly refracting crystals of showing different colours when examined in different directions.

**DICHROMATES.** Salts of the hypothetical acid  $H_2Cr_2O_7$ , v. CHROMIUM, ACIDS OF, p. 154, 157.

**DICONIC ACID**  $C_6H_8O_8$ . [200°]. Formed by heating citric acid with conc.  $HClAq$  at 200° (Hergt, J. pr. [2] 8, 372); aconitic acid seems to be an intermediate body. Small crystals, v. sol. water, alcohol, and ether. Reddens litmus.

**Salts.**— $K_2A''$ : deliquescent. —  $(NH_4)_2A''$ : [95°]; deliquescent crystalline mass. —  $BaA''\frac{1}{2}aq$ : more sol. cold than hot water. —  $BaH_2A''_2$ . —  $SrA''\frac{1}{2}aq$ . —  $CaA''\frac{1}{2}aq$ . —  $MgA''\frac{1}{2}aq$ : hard crystalline crusts, v. sol. water. —  $Fe(OH)_2HA''$  (?). —  $MnA''\frac{1}{2}aq$ : plates. —  $CoA''\frac{1}{2}aq$ : rose-coloured monoclinic plates. —  $NiA''\frac{1}{2}aq$ . —  $ZnA''\frac{1}{2}aq$ : monoclinic plates. —  $ZnH_2A''_2\frac{1}{2}aq$ . —  $CuA''\frac{1}{2}aq$ : bluish-green prisms. —  $SnA''\frac{1}{2}aq$ : insoluble pp.

**Diethylether Et.A''**. Oil.

**DIDYMIUM** Di. At. w. 143 (exact value doubtful). Mol. w. unknown. S.G. 6.544. S.H. 04568 (Hillebrand, P. 158, 71). Melts above Ce and La. In 1842 Mosander separated a new metal from the mineral *Cerite* (P. 56, 503); as the metals Ce and La had already been found in this mineral, the name *didymium* was given to the new metal to suggest its close relationship to lanthanum ( $\delta\delta\gamma\mu\sigma$  = two-fold). Recent investigation has succeeded in obtaining from certain Di salts what seem to be two classes of compounds distinguished by their absorption-spectra and colour; these compounds in all probability are salts of two distinct elements (v. *infra*); the name *didymium* is therefore a singularly happy one. In the present state of knowledge of the rarer elements it seems well to describe the body regarded until recently as a single element, and the compounds of this body.

**Occurrence.**—As silicate in various Scandinavian and Siberian minerals, *Cerite*, *Gadolinite*, *Orthite*, &c., accompanying Ce and La.

**Preparation.**—The mixed oxides of Ce, La, and Di are separated from *Cerite* by treatment with  $H_2SO_4$ , &c., as described under *CERURIUM* (vol. i. p. 723); Ce is then separated as basic nitrate by one of the methods described under *CERURIUM*. The solution of Di and La nitrates may then be treated in different ways: Bunsen and Jørgen (P. 155, 377) recommend ppn. of the hydrated oxides of Di and La by  $NH_4Aq$ , solution in  $H_2SO_4Aq$ , evaporation, and crystallisation of the sulphates; the sulphates are then dried and powdered, 1 part is dissolved in small successive portions in 6 parts water at 2°–3°, the solution is heated

to c. 40°, when  $La_2SO_4$  separates, the mother-liquor is slowly evaporated by standing in a warm place, when rose-coloured rhombohedra of  $Di_2SO_4$  separate; thin violet plates generally also form on the sides of the dish, these are a mixture of the two sulphates, they are easily distinguishable from the  $Di_2SO_4$  crystals; the rose-coloured crystals are picked out, and purified by re-crystallisation (Mosander, P. 56, 503, or P. M. 28, 241). The crystals thus obtained usually contain a little  $La_2SO_4$ ; Hermann (J. pr. 82, 385) evaporates the solution of  $Di_2SO_4$  containing some  $La_2SO_4$  to dryness at about 18°–20°, adds a little cold water to the residue which dissolves  $Di_2SO_4$  with very little  $La_2SO_4$ , evaporates to dryness at 18°–20°, treats with cold water, &c., and repeats these operations so long as there is any residue not quickly sol. in a little cold water. To complete the separation, Hermann (*loc.*) dissolves the  $Di_2SO_4$ , which may contain traces of  $La_2SO_4$ , in water, divides the solution into two parts, ppts. one part by  $NH_4Aq$ , washes the pp. thoroughly, mixes it while moist with the other part of the solution, and allows the whole to remain at a moderate temperature for some days; basic La sulphate thus dissolves completely and basic Di sulphate separates; after a few days the crystals which separate are collected, washed, dissolved in  $H_2SO_4Aq$ , and again crystallised (v. also Erk, Z. [2] 7, 104).

Other methods for separating Di salts from La salts are based on the relative solubilities of the oxalates and nitrates of the two metals; v. Marignac, A. Ch. [3] 27, 226; Holzmänn, Zeitschr. für Chem. und Pharm. 1862, 668; Zschiesche, J. pr. 107, 65; Frerichs a. Smith, A. 191, 331. Frerichs (B. 7, 798) describes a method of separation founded on the reaction between  $DiCl_3$  and  $LaOCl$ , whereby  $Di_2O_3$  and  $LaCl_3$  are produced.

According to Cleve (C. J. 43, 362) the  $Di_2SO_4$ , prepared as described may still contain samarium salts; samarium oxide is separated by long continued fractional ppn. with cold dilute  $NH_4Aq$ , the earlier fractions are rich in samaria, the later are chiefly didymia; by solution of the later portions in  $HNO_3Aq$  and repeated fractional ppn. by dilute  $NH_4Aq$ , didymia is at last obtained free from samaria. (Cleve's paper contains a description of a method for the approximate separation of the rare earths, which he says is very convenient.)

The  $Di_2SO_4$ , purified as described is dissolved in water, and  $NH_4Aq$  is added in excess, the ppd. hydrate is washed, and dissolved in  $HClAq$ , the liquid is evaporated after addition of  $NH_4Cl$ , and the residue is heated; nearly pure  $DiCl_3$  containing a little  $DiOCl$  is obtained. The  $DiCl_3$  may be reduced by heating with K in a porcelain tube; on washing with water small particles of Di are obtained (Marignac, A. Ch. [3] 88, 148); the reduction is better effected by mixing with  $NaCl$ , melting, and electrolysis (Hillebrand a. Norton, P. 155, 633).

**Properties and Reactions.**—White metal, malleable and ductile, harder than Ce. Oxidises in air; when finely divided it burns in a flame with production of much light; dissolves readily in dilute  $HClAq$ ,  $HNO_3Aq$ , and  $H_2SO_4Aq$ ; decomposes cold water slowly and hot water rapidly.

The atomic weight of Di has been determined (1) by analysing the sulphate (Marignac, *A. Ch.* [3] 27, 231; Erk, *Z.* [2] 7, 106); (2) by analysing the chloride (Marignac, *A. Ch.* [3] 38, 153); (3) by transforming the oxide into sulphate, or *vice versa* (Hermann, *J. pr.* 82, 387; Erk, *Z.* [2] 7, 106; Zschiesche, *J. pr.* 107, 65; Cleve, *Bl.* [2] 21, 246; 39, 289; *C. J.* 43, 362; Brauner, *C. J.* 41, 68, and (later) *W. A. B.* 3, 141, 499); (4) by determining S.H. of Di, Hillebrand & Norton (*P.* 158, 71). The numbers obtained for the atomic weight of Di vary from c. 145 to c. 142; Cleve thinks that the value  $142.124 \pm .0326$  may be accepted; Brauner thinks that  $Di = 145.2$  to  $145.4$  (*C. J.* 43, 288).

**Separation of didymium into different constituents.**— $La-NH_4$  nitrate is more sol.  $HNO_3$  aq than  $Di-NH_4$  nitrate; when a long process of fractional crystallisation is conducted with a mixture of these salts, the  $La$  salt may be completely removed, and at the same time the  $Di$  salt separated, according to v. Welsbach, into two perfectly distinct compounds (*Sitz. W.* 92 [2nd part], 317). A large quantity of the mixed nitrates of  $La$  and  $Di$  obtained from *cerite* after separating basic  $Ce$  nitrate (v. vol. i. p. 723) is mixed with the necessary quantity of  $NH_4NO_3$ , about  $\frac{1}{2}$ th part conc.  $HNO_3$  aq is added, and the liquid is evaporated until small crystals appear on the surface, a little water is added, and crystallisation is allowed to proceed for about 24 hours; the crystals are drained and washed with a little  $HNO_3$  aq which is added to the mother-liquor; the mother-liquor is evaporated and crystallised; the liquor from this is again evaporated, and so on until 6-8 fractions have been obtained; these fractions are then systematically refractionated by crystallisation from  $HNO_3$  aq several thousand times. Two nitrates are finally obtained, one forming a pale-green solution, the other forming a rose-coloured solution; these solutions give different emission- and absorption-spectra, the sum of the two spectra is the same as the spectrum of didymium nitrate. From each solution salts are obtainable, one series is green, the other is rose-coloured; by decomposing the green nitrate by heat a brownish-black oxide is obtained, and by decomposing the rose-red nitrate a blue-grey oxide is produced; analyses of the oxides and salts are not given in the original paper. For the element which forms green salts v. Welsbach proposes the name *praseodymium*, and for that which gives rose-coloured salts he proposes the name *neodymium*; he assigns the atomic weight 143.6 to praseodymium, and the atomic weight 140.8 to neodymium, the oxides having the composition  $M_2O_3$ . When a salt of praseodymium is mixed in certain proportions with a salt of neodymium, the spectrum of the mixture is the same as that of didymium.

Becquerel (*C. R.* 104, 1691; 777) has examined the absorption-spectra of  $Di$  salts, and concludes that these salts are mixtures of at least two substances. Brauner (*C. J.* 43, 281) got indications of the complex nature of  $Di$  by careful fractional ppg. of  $Di_3NO_3$  solution by  $NH_4$  aq. Crookes (*N.* 34, 266) did not succeed in separating v. Welsbach's praseo- and neodymium from didymium; he thinks that these names may represent two different groups of

molecules into which what is called didymium is separated by one particular method of fractionation.

**Chemical relations of Didymium.**—If the body called didymium is an elementary substance, it must be placed in Group V. with  $N$ ,  $P$ , ... and  $Bi$ .  $Di$  forms the oxide  $Di_2O_3$ , and probably  $Di_2O$ , but only one class of salts  $Di_3X$  where  $X = SO_4, 2NO_3$ , &c.; one class of haloid salts is known,  $DiX_3$ , where  $X = F, Cl, Br$ ; the oxychloride  $DiOCl$  has been prepared.  $Di$  is more closely analogous to  $Bi$  than to any other element of Group V.

Didymium arsenate v. vol. i. p. 308.

Didymium bromide  $DiBr_3 \cdot 6H_2O$ . Violet, deliquescent crystals; S.G. 2.81 (Cleve, *Bl.* [2] 39, 289); obtained by dissolving  $Di_2O_3$  in  $HBr$  aq and evaporating over  $H_2SO_4$ . Forms double salts (Frerichs & Smith, *A.* 191, 342):  $2DiBr_3 \cdot 3NiBr_2 \cdot 18H_2O$ ;  $2DiBr_3 \cdot 3ZnBr_2 \cdot 36H_2O$  ( $24H_2O$  according to Cleve, *Bl.* [2] 39, 289), very deliquescent;  $DiBr_3 \cdot AuBr_3 \cdot 10H_2O$  (Cleve, *l.c.*).

Didymium chloride  $DiCl_3 \cdot 6H_2O$ . Violet, deliquescent, monoclinic crystals; very soluble in water or alcohol; S.G. 2.286 (Cleve, *l.c.*). Obtained by dissolving  $Di_2O_3$  in  $HCl$  aq, evaporating, and crystallising; when the solution is evaporated to dryness after addition of  $NH_4Cl$  and the residue is heated, or when the residue obtained by evaporating  $Di_2O_3$  in  $HCl$  aq to dryness is heated in a stream of  $HCl$ , nearly pure  $DiCl_3$ , containing a little  $DiOCl$ , is obtained.

Double salts.— $2DiCl_3 \cdot 3AuCl_3 \cdot 2H_2O$ ; brilliant yellow deliquescent plates, by evaporating a solution of the mixed chlorides (Frerichs & Smith, *A.* 191, 340);  $2DiCl_3 \cdot 9HgCl_2 \cdot 24H_2O$ ;  $2DiCl_3 \cdot 3PtCl_4 \cdot 24H_2O$  (F. & S.);  $DiCl_3 \cdot PtCl_4 \cdot 10H_2O$ , deliquescent prisms; S.G. 2.689 (Cleve, *Bl.* [2] 39, 289);  $DiCl_3 \cdot SnCl_4 \cdot 10H_2O$  (Cleve, *Bl.* [2] 31, 196).

Didymium fluoride  $2DiF_3 \cdot H_2O$ ; reddish pp. by adding  $HFA$  aq to solution of  $Di$  acetate (Cleve). According to Frerichs & Smith (*A.* 191, 343) the pp. formed by adding  $HFA$  aq to  $Di_3SO_4$  aq is  $2DiF_3 \cdot 3HF$ ; this is denied by Cleve (*B.* 11, 910).

Double salts.—Obtained by treating  $Di_2O_3$  with  $KF \cdot HF$  (Brauner, *C. J.* 41, 68);  $2DiF_3 \cdot 3HF \cdot H_2O$ ;  $3DiF_3 \cdot 3KF \cdot H_2O$ ;  $4DiF_3 \cdot 3KF$ .

**Didymium hydroxides v. DIDYMIUM, OXIDES AND HYDRATED OXIDES OF.**

Didymium iodide. Not isolated. Frerichs & Smith (*A.* 191, 343) obtained the double salt  $2DiI_3 \cdot 3ZnI_2 \cdot 24H_2O$  as deliquescent yellow plates.

**Didymium, oxides and hydrated oxides of.**  $Di$  forms the oxide  $Di_2O_3$ ; another oxide  $Di_2O$ , and another intermediate between these,  $Di_2O_2$ , or  $Di_2O_4$ , probably exists. The hydrated oxide  $Di_2O_3 \cdot 3H_2O$  seems not to have been obtained in a state of purity;  $Di_2O_3 \cdot 3H_2O$  has probably been isolated. The oxides and hydrated oxides of  $Di$  are basic; the higher oxides react with acids as peroxides, forming salts of the series  $Di_2SX$  ( $X = NO_3, SO_4, \&c.$ ).

**DIDYMIUM OXIDE**  $Di_2O_3$ . S.G. 7.18 (Cleve, *Bl.* [2] 39, 289); S.H. .081 (Nilson & Pettersson, *B.* 13, 1459). Obtained by ppg.  $DiCl_3$  aq by  $KOHA$  aq, and strongly heating the hydrated oxide thus formed; also by strongly heating  $Di(NO_3)_3$ ,  $Di_2(C_2O_4)_3$ , or  $Di_2(CO_3)_3$ ; it is advantageous to

complete the decomposition in a stream of  $H_2O$  to deoxidise any higher oxide formed. Greyish-blue solid (Cleve, *Bl.* [2] 30, 289); white without any blue tinge according to Hermann (*J. pr.* 82, 585). Unchanged by heating in  $H_2$ ; probably combines with  $O$  when heated in that gas (*v. infra*). Emits white light when very strongly heated, the lines in the spectrum of the light emitted are the same as the dark lines in the absorption-spectrum of dilute  $Di$  salt solutions. Dissolves in acids to form salts  $Di_3X$  where  $X = NO_3, SO_4, \&c.$  Insoluble in water, but in hot water forms a hydrate probably  $Di_3O_8 \cdot 3H_2O$ . In ordinary air forms  $Di_3CO_3$ ; decomposes hot solutions of  $NH_4$  salts, evolving  $NH_3$ .

HYDRATED DIDYMIUM OXIDE?  $Di_3O_8 \cdot 3H_2O$  ( $= Di(OH)_3$ ). The pp. obtained by adding  $KOH$  or  $NaOH$  to solutions of  $Di$  salts is gelatinous, pale rose-red, insoluble in excess of the ppt.; it always contains a little carbonate.  $NH_4$  ppts. basic salts from solutions of  $Di$  salts. Thomsen gives the heat of neutralisation of didymium hydrate  $[Di_3O_8 \cdot 3H_2O \cdot 3H^+SO_4^-] = 77,160$  (*Th.* 1, 375).

OXIDES OF DIDYMIUM OTHER THAN  $Di_3O_8$ . According to Frerichs a. Smith (*A.* 191, 314),  $Di_3O_8$  prepared by gently heating  $Di(NO_3)_3$  absorbs  $O$  when heated in that gas, forming a chestnut-coloured powder approximating to the composition  $Di_3O_8$ . The same chemists also obtained  $Di_2O_3$  by heating  $Di_2(C_2O_4)_3$  in a stream of  $O$ . Hermann (*J. pr.* 82, 385), by heating  $Di_3O_8$  in  $O$ , obtained a product with only c. .8 p.c. more  $O$  than  $Di_3O_8$ ; Cleve (*B.* 11, 910) states positively that  $Di_2O_3$  cannot be obtained as described by Frerichs a. Smith. Brauner (*C. J.* 41, 68) says that the oxide obtained by carefully heating basic  $Di$  nitrate to dull redness in a stream of  $O$  has the composition  $Di_3O_8$ ; he describes this oxide as an amorphous chocolate-brown powder, soluble in dilute  $HNO_3$  or dilute  $H_2SO_4$  without evolution of gas, but soluble in more conc. acids with evolution of  $O$ , insoluble in  $HFAc$ , decomposed when strongly heated with production of  $O$ ; reduced in  $H$  at low red heat; S.G. at  $15^\circ = 5.368$ ; reacts with acids to form salts  $Di_3X$ , and must therefore be classed as a basic peroxide. Brauner (*l.c.*) ppd. a solution of  $Di_3NO_3$ , containing  $H_2O_2$ , by dilute  $KOH$  and dried *in vacuo*, he thus obtained a light red powder to which he assigns the formula  $Di_3O_8 \cdot 3H_2O$ . It is still uncertain whether Brauner's peroxide can be obtained from a specimen of  $Di_3NO_3$  perfectly free from samarium.

**Didymium oxyhaloid compounds of.** The only one of these compounds definitely known is the *oxychloride*,  $DiOCl$ ; it is a greyish powder, S.G. 5.761 (Cleve, *Bl.* [2] 39, 151), obtained by heating  $DiCl_6 \cdot 6H_2O$  and treating the residue with water (Marignac, *A. Ch.* [3] 38, 148), or, according to Frerichs a. Smith (*A.* 191, 341), by heating  $Di_3O_8$  in  $Cl$  at  $200^\circ$ .

**Didymium oxysulphide.** Marignac (*A. Ch.* [3] 88, 148) describes a greyish powder, insoluble in water, obtained by heating  $Di_3O_8$  with  $S$  and  $NaOH$ ; he gives it the formula  $Di_3O_8S$ .

**Didymium salts of.**  $Di$  forms one class of salts,  $Di_3X$ , where  $X = NO_3, SO_4, \&c.$ ;

many of them are soluble in water, forming rose-red liquids; several double salts, but very few basic salts, are known. The chief salts are borate, bromate, carbonate, chlorate, iodate, molybdate, nitrate, oxalate, phosphates, selenate and selenite, sulphate and sulphite, tungstate, vanadate; *v.* CARBONATES, NITRATES, SULPHATES, &c.

**Didymium sulphide**  $Di_3S_8$ . A brownish-green powder; obtained by heating  $Di_3O_8$  in  $H$  charged with  $CS_2$  vapour. Decomposed easily by acids with evolution of  $H_2S$ ; decomposed by heat to  $Di_3O_8$  and basic  $Di$  sulphates (Marignac, *A. Ch.* [3] 38, 148; Frerichs a. Smith, *A.* 191, 345).

**Didymium sulphocyanide** *v.* SULPHOCYANIDES under CYANIDES, p. 350. M. M. P. M.

**DIFFUSION.** The mixing or mutual interpenetration, by reason of the movements of the minute particles of the fluids, of gases or liquids which do not chemically interact, is called *diffusion*, whether the fluids are in immediate contact or are separated by porous partitions. When a liquid passes through a membrane into another liquid the process is generally called *osmotic diffusion* or simply *osmose*; when the diffusion of a liquid is accompanied by a separation, partial or complete, into two or more chemically different bodies, the process is generally known as *dialysis*. Substances which when in solution pass freely through a porous membrane, or readily diffuse into another liquid in contact with them, are generally called *crystalloids*, while those substances, solutions of which do not diffuse, or diffuse very slowly, are usually called *colloids*. For an account of *diffusion* and the applications of this process to chemical questions *v.* PHYSICAL METHODS, vol. IV, p. 172.

M. M. P. M.

**DIGITALIN** C 58.2 p.c.; H 8.7 p.c. S (cold 90 p.c. alcohol) 84; (boiling 90 p.c. alcohol) 17. Occurs in the leaves of the common foxglove (*Digitalis purpurea*). It may be extracted from the leaves by dilute (50 p.c.) alcohol; the solution treated with basic lead acetate, and the filtrate, freed from excess of lead by  $Na_2CO_3$  ppd. by tannin. The digitalin tannate is then decomposed by lead oxide and the liberated digitalin crystallised from alcohol (Lefert, *J. Ph.* [5] 6, 424; cf. Nativelle, *J. Ph.* [4] 9, 255; 20, 81; *Ph.* [3] 2, 865; Le Royer, *Bibl. Univ.* 26, 102; Lancelot, *A.* 12, 251; Trommsdorff, *A.* 24, 210; *Ar. Ph.* 10, 113; Homolle, *J. Ph.* [3] 7, 57; O. Henry, *J. Ph.* [3] 7, 460; Hoinolle a. Quavenne, *Mémoires sur la Digitaline*, Paris, 1951; *Repert. Pharm.* [3] 9, 2; *Walz. Jahrb. pr. Pharm.* 14, 20; 21, 29; 24, 86; 26, 296; *Gerh.* 4, 236; *N. Jahrb. Pharm.* 8, 333; 9, 302; 10, 319; *J.* 1817, 645; 1851, 567; 1852, 679; 1853, 563; 1857, 520; 1858, 523; Delfts, *N. Jahrb. Pharm.* 9, 26; *J.* 1858, 523; Kossmann, *J. Ph.* [3] 33, 5; [4] 20, 427; *C. J.* 28, 650; Flückiger, *N. Jahrb. Pharm.* 39, 129; *C. C.* 1873, 371; Goerz, *J.* 1873, 815; Schneideberg, *Ph.* [3] 5, 741; Morin, *J. Ph.* [3] 7, 294).

**Properties.**—Slender needles grouped around a common axis (Nativelle) or small minute plates (Flückiger). Insol. water and dilute alkali, *v.* sol. ether, *v.* sol. chloroform, chloroform-alcohol, and acetic acid. Hydrochloric acid dissolves it, forming a yellowish solution, slowly becoming

emerald-green. Conco.  $\text{H}_2\text{SO}_4$  and  $\text{H}_3\text{PO}_4$  also give green colours. Digitalin has no smell but a bitter taste. It is poisonous, acting on the heart. Split up by boiling dilute acids into glucose, digitaliretin (C. 66 p.c.; H. 4.6 p.c.), and other bodies (Kossmann). Treatment with  $\text{H}_2\text{SO}_4$  (1 pt.) and alcohol (1 pt.) containing a few drops of aqueous  $\text{FeCl}_3$  gives a greenish-blue solution (Lafon, *Bl.* [2] 44, 18). Digitalin, being a glucoside, colours a hot mixture of bile and  $\text{H}_2\text{SO}_4$  red (Pettenkofer's reaction; cf. Brunner, *B.* 6, 96).

**Digitalein** C 53.2; H 8.1 p.c. An amorphous substance occurring in the leaves of *Digitalis purpurea* and *D. lutea*. V. sol. water and cold alcohol, sl. sol. chloroform, insol. ether. Ppd. from its aqueous solution by tannin or lead subacetate. Split up by dilute acids into glucose and digitaliretin. Narcotic poison.

**Digitin** ( $\text{C}_{12}\text{H}_{22}\text{O}_{10}$ )? Occurs in foxglove leaves. Stellate groups of needles, insol. water, chloroform, and benzene, v. sol. ether and alkalis (Goerz, *J.* 1873, 814).

**Digitonin** C 53.4 p.c.; H 7.5 p.c. A white amorphous substance occurring in foxgloves. Resembles saponin and melanthin. V. sol. water, forming a solution that froths on shaking. Ppd. from its aqueous solution by alcohol, baryta-water, or lead subacetate. Gives a red colour when boiling with dilute acids (Greenish, *Ph.* [3] 10, 909; 1013).

**Digitoxin** C 63.6 p.c.; H 8.1 p.c. Occurs in the leaves of the foxglove. Needles or tables, insol. water and benzene, sl. sol. ether, v. sol. alcohol and chloroform. Boiling dilute acids convert it into amorphous soluble toxiresin. Both digitoxin and toxiresin are very poisonous. According to Kopp digitoxin is eight times as poisonous as digitalin.

**DILUTIC ACID** v. NITRO-BARBITURIC ACID.

**DILL OIL.** S.G. .9. (c. 190°). The volatile oil of *Apium* (or *Anethum graveolens*). It contains carvene and carvol (Wallach, *A.* 227, 292; cf. Nietzki, *Ar. Ph.* [3] 4, 317; Gladstone, *C. J.* 17, 1; 25, 1).

**DIMORPHISM** and **TRIMORPHISM.** These terms are used to denote the existence of the same chemical substance, elementary or compound, in different crystalline forms. The two kinds of crystals of a dimorphous body, or the three kinds of crystals of a trimorphous body, may belong to different systems, e.g. carbon crystallises in the regular system as diamond and in hexagonal forms as graphite; nickel sulphate crystallises in trimetric prisms, in dimetric octahedra, and in monoclinic prisms; or the different crystals of the same body may belong to the same system, and yet so differ in their corresponding angles that they cannot be reduced to the same form; mono-sodium phosphate, for instance,  $\text{NaH}_2\text{PO}_4 \cdot x\text{H}_2\text{O}$ , crystallises in two different trimetric forms. Di- and tri-morphism is usually accompanied by differences of S.G., colour, hardness, or other properties (v. CRYSTALLISATION and ISOMORPHISM). M. M. P. M.

**DIOSMIN** C 53 p.c.; H 6.1 p.c. [243°].

**Occurrence.**—In the leaves of *Barosma crenata* and *betulina* (Cape of Good Hope).

**Preparation.**—The leaves are first extracted with petroleum to remove the essential oils together with chlorophyll, a wax and a resin; then they are extracted with cold, and finally with

hot, alcohol (80–85 p.c.). The diosmin is obtained by heating with ammonium carbonate, and finally washing with alcohol and ether (P. Spica, *G.* 18, 1).

**Properties.**—White or yellowish-white crystals, insol. most solvents, but sol. hot alcohol (80–85 p.c.). In composition it is practically identical with hesperidin (Paternò a. Briosi, *G.* 6, 169). Reduces Fehling's solution. Dissolves in concentrated acids and alkalis, but is reppd. on neutralisation. Heated with concentrated mineral acid it is decomposed into a glucose and an orange-yellow crystalline substance [145°]. Shimoyama (*Archiv der Pharm.* 1887) considers the similar glucoside hesperidin to be present in the leaves of various species of the *Barosma*.

**DIOSPHENOL**  $\text{C}_{10}\text{H}_{16}\text{O}_2$ . [82°]. (c. 230°). The stearoptene in oil from buchu leaves (Spica, *G.* 15, 195; Shimoyama, *Ar. Ph.* [3] 26, 403). Monoclinic crystals (by sublimation); v. sol. alcohol, sl. sol. ether, insol. water. Smells like camphor.  $\text{FeCl}_3$  gives a green colour.

**Reactions.**—1. Alcoholic KOH partly converts it into diolic acid  $\text{C}_{10}\text{H}_{16}\text{O}_4$ , which forms the following salts:  $\text{BaA}'_2 \cdot 5\text{aq}$ . B. 1. f at 17.5°; 5 at 100°.— $\text{AgA}'$ .—2. Reduction in alcoholic solution by sodium amalgam forms  $\text{C}_{10}\text{H}_{18}\text{O}$ , [159°].—3. Bromine gives  $\text{C}_{10}\text{H}_{16}\text{Br}_2\text{O}_2$ , [43°].

**Methyl derivative**  $\text{C}_{10}\text{H}_{16}\text{MeO}_2$ . (234°). S.G. 1.2985. From diosphenol, KOH, and Mel.

**Ethyl derivative**  $\text{C}_{10}\text{H}_{16}\text{EtO}_2$ . (271°). S.G. 1.2967.

**Acetyl derivative**  $\text{C}_{10}\text{H}_{16}\text{AcO}_2$ . (270°). S.G. 1.291032.

**DIPPEL'S OIL.** An oil obtained by rectifying the oily product of the destructive distillation of bones or other animal matter. Recommended as a medicine by Dippel, an apothecary of the seventeenth century; v. BONE-OIL, vol. i. p. 522.

**DISACRYL** v. ACROLEIN.

**DISPOLINE**  $\text{C}_{10}\text{H}_{14}\text{N}$ . (282°–304°). An alkaloid homologous with quinoline found among the products obtained by distilling cinchonine with potash (Greville-Williams, *Laboratory*, p. 109; *Z.* 1867, 428). Oil.— $\text{B}^+\text{H}_2\text{PtCl}_4$ . Not decomposed by boiling water (De Coninck, *Bl.* [2] 40, 271).

**DISSOCIATION.** A term proposed by Deville for the purpose of particularising a certain class of reactions chiefly studied by himself and by those whom he inspired.

Many facts now studied by the method of the theory of dissociation have been known from early days. The observations of Gay-Lussac on the decomposition of chalk by heat, and of Avogadro in 1811, and Ampère in 1814, on the abnormal vapour densities of gases may be mentioned. The starting-point of the modern doctrine is Grove's Bakerian Lecture (*T.* 1847), in which the decomposition of gases by heat, and especially the decomposition of water by fused platinum, is announced and explained. The following extracts will show that the theory of the decomposition of water was correctly stated by Grove, though the terms in which he expresses it are now obsolete. After describing the action of a hot platinum wire on dry and wet carbonic oxide respectively, he continues:—

'I thought much upon this experiment; it appeared to me ultimately that the ignited platinum had no specific effect in producing either composition or decomposition of

Q C

water, but that it simply rendered the chemical equilibrium unstable, and that the gases then restored themselves to a stable equilibrium according to the circumstances in which they were placed with regard to surrounding affinities; that if the state of mixed oxygen and hydrogen gas were, at a certain temperature, more stable than that of water, ignited platinum wire would decompose water as it does ammonia.' 'It now appeared to me that it was possible to effect the decomposition of water by ignited platinum; that, supposing the atmosphere of steam in the immediate vicinity of ignited platinum were decomposed, or the affinities of its constituents loosened, if there were any means of suddenly removing this atmosphere I might get the mixed gases; or secondly, if, as appeared by the last two experiments, quantity had any influence, that it might be possible so to divide the mixed gases by a quantity of neutral ingredient as to obtain them by subsequent separation (or as it were filtration) from the neutral substance. Both these were realised.'

He then relates how on heating platinum in steam he got a small bubble of gas, which detonated when all was cold; and then says:—

'The experiment was then repeated, continuing the ignition for a longer time, but the gas could not be increased beyond a very limited quantity; indeed, it was not to be expected, as, supposing it to be a mixed gas, recombination of the excess would have taken place.'

The matter was taken up by Deville in 1857, who repeated Grove's experiments on a large scale. Advantage was taken of an old observation of Regnault concerning the action of molten silver on steam, and an equivalent method, in which silver is replaced by fused litharge, was described.

This is the first of the many ingenious methods invented by Deville for the study of dissociation-phenomena, and to him and his pupils we owe much of our knowledge on the subject. The appended bibliography (p. end of this article) will indicate the further history of the matter, as well as the more important memoirs which have appeared on the subject.

Before defining the meaning of the term *dissociation* it will be well to become in some measure acquainted with the simpler facts and arguments of the subject. Let  $AB$  be a tube

made of some material capable of resisting a high temperature, such as glazed porcelain. Let  $c$  be a porous septum, e.g. a plate of porous earthenware, fitted into the tube  $AB$ , so as to be air-tight in the ordinary signification of the term. Let there be means of placing the end  $n$  of the tube in connexion with an air-pump and gas-analysis apparatus. The end  $a$  can be closed by a non-porous stopper, and the tube is to be so placed that it can be raised to any desired temperature. The space  $ca$  can be filled with any gas or vapour, and the stopper at  $A$  furnished with such arrangements as to allow the pressure of the vapour in  $ca$  to be kept constant, whatever the temperature may be. Though such a combination of apparatus

as this has never been put together, and though it would be exceedingly inconvenient in practice, it is easy to understand, and will serve to establish the main principles of dissociation.

The part of the tube  $ca$  is supposed to be filled with saturated water-vapour, and is placed on the heating apparatus.  $nc$  is kept vacuum, or as nearly so as possible, by means of the air-pump. In now studying the changes produced in the water-vapour by the action of heat, let us direct our attention solely to the part of the tube  $ca$ . Then we know that, as the temperature increases from  $100^\circ$ , the dry steam in  $ca$  will expand at almost exactly the same rate as a permanent gas. In fact, if we made two air-thermometers at constant pressure, and filled one with dry air and one with unsaturated steam, they would keep together approximately till a very high temperature is attained—say, up to a red heat. After that we should observe that the expansion of the steam becomes greater than the expansion of air, and continues to increase, at all events up to the highest temperature we can reach experimentally. If we replaced the steam by the vapour of acetic acid the same phenomena would be observed, except that we should finally be able to reach a point where the coefficient of expansion of the acetic acid vapour attained a maximum; and it would decrease from that point till it again became the same as for air. The apparatus with the porous plate will enable us to give an explanation of the change in the coefficient of expansion of dry steam. We know that when we mix two volumes of hydrogen and one volume of oxygen and keep the mixture at a temperature a little over  $100^\circ$ , and then explode the gases by means of an electric spark, so that they may form water-vapour, and finally allow the temperature to become the same after explosion as it was before explosion, then the three volumes will become reduced to two volumes. In other words, oxygen and hydrogen when combined together only occupy two-thirds of the space they occupy before combination.

Now, suppose that we heat the water-vapour, and let us assume that the heating in some way undoes the combination of the hydrogen and oxygen, so that we no longer have pure water-vapour, but a mixture of water-vapour, oxygen, and hydrogen. If we further assume that the ratio of the weight of the uncombined gases to the weight of the steam increases as the temperature rises, we shall have a hypothetical explanation of the change in the coefficient of expansion. This hypothetical explanation may be converted into a real explanation by experiments performed with the apparatus described. The rate of diffusion of different gases through porous septa is very nearly inversely proportional to the square roots of the densities of the gases. Hydrogen, therefore, passes through porous septa four times as fast as oxygen and three times as fast as steam. If, therefore, the steam in the part of the tube  $ac$  be really decomposed, we shall be able to detect the decomposition by means of an analysis of the gases diffused into the part  $bc$ . In order to make the proof complete we must still show that no other change takes place in the steam in  $ac$ ; this would be very difficult to do directly, especially

for steam which only decomposes at very high temperatures, and therefore we must adopt a rather different method. If we can show that the change in the coefficient of expansion is proportional to the amount of steam decomposed at all temperatures, then we can deduce that the most important part of the change at all events is to be traced to the decomposition, or, as we shall say for the future, to the *dissociation*, of the steam. This may be done by means of our apparatus. Since the pressure in A C is kept constant, the 'partial pressure' produced by the hydrogen and oxygen will be proportional to the ratio of the weights of the uncombined gases to the weight of steam per unit volume. We know from experiment that the weights of gases diffused per unit time, under otherwise constant conditions, are proportional to the pressures, within the limit that the pressure is above some very small value depending on the kind of gas and the size of the pores in the septum. In all ordinary experiments the pressure is well above the limit. In order to simplify matters we will arrange our furnace so as to keep B C at the same temperature as A C, and let the air-pump work so fast that, however much gas comes through the plate, the vacuum is not perceptibly impaired. For a reason to be given further on, we will also allow the gas coming from B C to cool slowly, so that the hydrogen and oxygen may recombine. This will leave us with a mixture of water-vapour and hydrogen in our analysis apparatus. We have therefore to keep our diffusion-tube at different constant temperatures, allow the diffusion to go on slowly, and measure the amounts of hydrogen coming through per unit time. From what has been said, these quantities will be proportional to the dissociation at the temperature considered; and we have only to compare them with the coefficients of expansion at those temperatures to test our theory.

In no particular case does the evidence in favour of the hypothesis stated above amount to a complete demonstration. Thus in the case of bodies like sal-ammoniac, which decompose into substances chemically different from themselves, and therefore recognisable by chemical methods, no experiments have been made to show that the abnormal vapour density is *entirely* accounted for by the dissociation. Again, in the case of substances like nitrogen tetroxide and acetic acid, where the vapour-density is a function of the temperature, experiments have indeed shown that the quantities of heat absorbed at different temperatures, less the quantities of heat required to raise similar supposed less decomposable gases through the same range, are proportional to the rate at which the coefficient of expansion deviates from the normal. Unfortunately, in both these cases (the only ones specially studied as to this point) we have no chemical means of testing whether the supposed molecular decomposition takes place or not. In fact, some chemists consider it does not, but that we have in these cases merely a change comparable with that from the liquid to the gaseous state, and which does not take place at a definite temperature, but goes on gradually even though the liquid as such may have disappeared (v. Berthelot & Ogier, *A. Ch.* [5] 86, 882). In

other words, these chemists are inclined to attribute the change which takes place in the coefficient of expansion merely to the molecules of the gas increasing their mean distance from each other faster in these cases than in the standard cases. This view, however, would lead to a very serious modification of all our views as to the physical significance of the gaseous state. Avogadro's law would have to be abandoned amongst other things. On the other hand, if we consider that nitrogen tetroxide and acetic acid vapour suffer molecular decomposition, then we must allow that all other gases which are formed from their elements with condensation—like nitrous oxide, for instance—may also undergo a molecular decomposition, since their specific heats have small positive temperature-coefficients (Regnault). There is nothing surprising in this, in fact it is in complete accordance with the views of Clausius and Williamson and physicists generally on the meaning of the *definite composition of gases*. Ramsay and Young (*C. J.* 49, 790) have shown that the specific gravity of acetic acid vapour decreases as temperature rises, whether the pressure be large or small, and that the specific gravity also decreases as pressure falls, whether the temperature be high or low, but that the specific gravity of a normal vapour, such as that of alcohol or ether, increases as temperature falls until a limit is reached, after which the specific gravity remains unchanged.

The hypothesis of dissociation sketched above will therefore be adopted in what follows, for not only is it in complete harmony with every experimental fact observed, but it serves to co-ordinate and bring into the same field of view a very great number of experimental results, at first sight very unlike each other and inexplicable separately. It will be noticed that we have as yet said nothing as to the mechanism by which dissociation takes place; this is a very obscure subject, and indeed very often seems to depend, amongst other things, on the form and material of the containing vessel (Menschutkin & Kanonow).

The effect of porous surfaces, however, presents little difficulty to the kinetic, and still less to the vortex-ring, theory of gases. Practically it may be taken to mean that an experimenter attempting to reproduce any of the experiments described below will most probably fail to reproduce the numerical results unless he carefully copies the original experimenter's apparatus. Particular instances will be found in their proper places.

There is no reason to suppose that dissociation is limited to gases, or that a rise of temperature is the only physical condition capable of bringing it about. It is a matter of common experience that chalk, when heated, decomposes into quicklime and carbonic acid; and if the operation be conducted in a closed chamber so that the carbonic acid cannot escape, it is found that the decomposition of the chalk is never complete, and that recombination occurs, to a certain extent, when the temperature falls. There are many other substances which behave like chalk as far as their decomposition by heat is concerned; that is, their degree of decomposition in closed vessels is almost entirely a function of

the temperature, and is reversible. The constitution of solutions of many salts in water or in other solvents also appears to be dependent on the temperature. All these phenomena are collected together as cases of *thermolysis*, or decomposition by heat alone, and their study forms the larger part of the subject of *dissociation*, which also embraces cases of decomposition by other physical processes, such as exposure to light or electrical discharges.

There are many substances which undergo a complete and non-reversible chemical change under the action of heat; these decompositions may be regarded as cases of unlimited dissociation, and are generally called decompositions simply. Such unlimited changes are, however, best studied by themselves, and will not be dwelt upon in this article. For convenience of treatment we may define dissociation as follows:—

Let there be a chemical system consisting of atoms of kinds, A, B, C, &c., capable of combining together in any way; and let their actual state of combination at any instant depend partially on the physical conditions to which the system is exposed at the instant considered; and let the state of combination be called the state *y* when the physical conditions are denoted by *x*. Then if *y* changes when *x* changes, in such a way that *y* always returns to its original value when *x* returns to its original value, the system is called a *dissociable system*. In fact the value of *x* must be independent of the 'previous history' of the system; this necessarily implies that in dissociable systems the change of state of combination must be reversible. Dissociation, therefore, is the doctrine of reversible chemical reactions. Dissociation-processes are but special cases coming under the general laws of chemical equilibrium; as such they will be considered in the article **EQUILIBRIUM, CHEMICAL**.

The changes which take place in the energy of the system as its chemical constitution varies must necessarily exert a very great influence on the readiness with which such variation can occur. It is obvious, for instance, that the state of combination cannot change by itself from a condition of less to a condition of greater energy unless that energy be supplied from without. A supply of energy has therefore to be provided in order that many dissociation reactions may take place. In consequence of this, the thermal changes taking place during some cases of dissociation have been carefully studied (Berthelot); and much valuable information has been drawn, in other cases, from a consideration of the available energy of the electric field (J. J. Thomson).

Before treating special cases in detail it will be well to form a simple working hypothesis of dissociation, in order to shorten, as much as possible, the treatment of the experimental results. Such an hypothesis is ready to hand if we translate the results of, say, our experiments on steam, into the language of the kinetic theory of gases, and the ordinary molecular and atomic theory of chemistry. Taking the case of steam, we may sum up the results arrived at by saying that as the temperature rises the kinetic energy of the molecules increases, and in consequence the number of molecular collisions per second,

as well as the violence of these collisions, must also increase. When the atoms of oxygen and hydrogen are uncombined they will be called free atoms; when combined they will be called 'paired' atoms. The 'mean time' during which the atoms are free is called the 'mean free time,' and the time during which they are paired is called the 'mean paired time.' If in the case of a system of oxygen and hydrogen where we may have molecules of oxygen, hydrogen, and steam, as well as atoms of the two former, the actual state of combination at any instant will depend on the ratio of the paired to the free time. If the time during which the atoms of oxygen and hydrogen are paired together is long compared with the time during which they are free, or paired with atoms of the same kind as themselves, then we are considering what is equivalent to a volume of steam. If, however, the paired time is comparatively short, then the state of the system approximates more to that of a mixture of oxygen and hydrogen. If we assume that the ratio is altered by a variation of the frequency of collisions, or of their violence, or by any other variation produced by a rise of temperature, then we shall have increased decomposition if the ratio of paired time to free time decreases as the temperature increases. When the temperature falls, on the other hand, we shall get recombination.

We can, therefore, form a mental image of a purely mechanical character as to the way in which dissociation may take place. We should expect that the effects would be modified at the boundaries of the gaseous system; and that some of the phenomena observed might be traced to the influence of the state of the walls of the containing vessel; and so, in fact, it is. The presence of porous bodies in particular seems to exercise a profound influence on the chemical state of gaseous systems exposed to their action. The above hypothesis of the mechanics of dissociation is at present to be regarded as a mere hypothesis of the most arbitrary character: if we can justify it afterwards by cumulative evidence that is another matter.

It will also be convenient to take advantage of a very simple method of regarding the phenomena of dissociation first put forward by Pfaunder in 1867. We are to regard a system in which dissociation is taking place as a field in which two tendencies are at work; on the one hand a source of energy from without the system is tending to produce decomposition; and on the other the 'chemical nature' of the component parts of the system is tending to produce recombination. Without committing ourselves to explain in any way the *modus operandi* of these tendencies, we can see that it is possible for the system to attain a state such that the amount of decomposition and recombination per unit time is the same. When this state is reached the 'limit of the reaction' is said to be attained. If by raising the temperature of the system, or by any other means, we alter the potency of one of the tendencies, we shall have a new equilibrium or limit. The idea is that for every given set of conditions we shall have a definite equilibrium, which will alter when the conditions alter, and which is therefore called a 'mobile equilibrium.'

The ratio of the weight of the uncombined part of the system to the weight of the whole system which is capable of combination is called the 'fraction of dissociation,' and is a very convenient quantity in discussing dissociation phenomena. Thus in a system of hydriodic acid, weighing say 10 grams before dissociation takes place, we might arrive at a temperature such that 1 gram became decomposed; then the fraction of dissociation would be denoted by  $\frac{1}{10}$ , and would be expressed by the same number whether we added iodine or hydrogen in excess, or, indeed, any inert gas.

If the external conditions change, then a period of time, short or long, is required for a new equilibrium to be established. Different writers have adopted different methods of expression for the rate at which the new equilibrium tends to become established, and various arbitrary rules have been given for finding the velocity of the reaction, depending of course on special definitions of the expression 'velocity of reaction.' In some cases the velocity of the reaction has been defined as the weight of substances combined or decomposed per unit time in a system of arbitrarily chosen weight. The most exact method would be to define 'velocity' as the rate at which the fraction of dissociation changes. The particular definition which we may happen to adopt is not of any very great importance, since it is from a comparison of velocities, and not from their absolute value, that useful information is most readily obtained.

The object of experiment is to determine the relation existing between the fraction of dissociation, when the limit is attained, and the other quantities involved. The most important of these are temperature, pressure, and proportion of reacting substances. The velocities of the reactions must also be studied experimentally.

We follow Lemoine in his distinction between the reactions which take place in homogeneous systems, and those which occur in non-homogeneous systems. If we start with a homogeneous system and by dissociation convert it into a system which is not homogeneous, we should expect a corresponding modification in the reaction, and such is the case. The most valuable results will be obtained when the experimental conditions are as simple as possible; and therefore more attention ought to have been devoted to the dissociation of systems which remain homogeneous than to those which are non-homogeneous to start with, or which become so by dissociation. Unfortunately, however, it is difficult to experiment on homogeneous systems.

Qualitative experiments whereby the existence of the dissociation of compounds was established.—Regnault describes some experiments under the article 'Chaux' (*Cours élémentaire de Chimie* [1854], 2, 2,3,5) which show that some solid bodies, decomposable by heat into one or more solids and a gas, give off the gas more freely when in presence of a foreign gas than when exposed to the products of their own decomposition. Chalk loses its carbonic acid more freely in ordinary air than in an atmosphere of carbonic acid. Hydrated salts lose their water of hydration more readily in an

atmosphere of dry air than in one of water vapour. Grove, as we have seen, demonstrated the decomposition of steam by heat, and pointed out that the condition that the decomposition shall be sensible is that the products of decomposition must be rapidly cooled, or in some other suitable way removed from the sphere of action before recombination can take place. From a theoretical point of view it is immaterial whether we hinder recombination by preventing the atoms from getting to one another through admixture with an inert gas, or whether we lower the temperature so rapidly that it falls below the combination point before all the atoms are recombined.

Deville first laid down these principles with great clearness, and practically invented all the apparatus requisite for the realisation in practice and on a large scale of the necessary conditions. His apparatus is of three kinds.

I. For raising gases to a high temperature, and removing, at that temperature, the products of dissociation, by taking advantage of the laws of gaseous diffusion.

II. For raising gases to a high temperature and preventing recombination by admixture with an inert gas.

III. For raising gases to a high temperature and preventing recombination by sudden cooling. This apparatus took two forms:—

*a* The hot and cold tube.

*β* Apparatus for sucking the hot gases into a tube through which water is circulating.

Exact information may be obtained from Deville's papers (v. Bibliography); and especially from his *Leçons sur la Dissociation professée en 1864 devant la Société Chimique*.

I. A glazed porcelain tube is fitted with good corks at each end; through these corks, and concentric with the axis of the porcelain tube, another tube of unglazed earthenware is passed. The porcelain tube can be heated, by means of a suitable furnace, to a very high temperature. The gas to be decomposed is made to circulate through the annular space between the two tubes. A current of an inert gas continually passes through the tube of unglazed earthenware and sweeps away with it the products of diffusion (v. fig. 1).

Deville decomposed steam by means of this apparatus, using carbon dioxide as the inert gas; the carbon dioxide was subsequently absorbed by potash, leaving a mixture of oxygen and hydrogen.

II. A porcelain tube is filled with pieces of porcelain in order to expose a large surface. The gas to be decomposed is mixed with a much larger volume of some inert gas and passed through the tube which is heated as before. This apparatus is not so powerful as the one last described. In an experiment in which a mixture of steam and carbon dioxide was passed through the apparatus, the yield of explosive mixture of oxygen and hydrogen was much smaller than when the porous tube was used; though of course in that case the mixture was chiefly hydrogen. This method is less applicable to quantitative experiments because of the complication introduced by the action of the large extent of porcelain surface exposed.

IIIa. *The hot and cold tube*: this was used first for demonstrating the decomposition of carbonic oxide into carbon and carbon dioxide. It resembles form I. with the modification that the porous central tube is replaced by a tube of silver through which a stream of cold water is kept constantly flowing. The decomposition of the carbonic oxide gas was proved by the deposition of carbon on the silvered tube, and by the presence of carbon dioxide in the stream of gas which passed through the tube.

IIIb. An apparatus of the same kind as the last, but with the important modification that a small hole of 2 mm. diameter is bored in the side of the metal tube. The result is that when a stream of water is allowed to flow through the tube, air is sucked in at the small hole after the manner of a velocity pump. This apparatus was employed by Deville to examine the constitution of the gases in the middle of a candle flame; and was afterwards employed by Cailletet for extracting the gases from a blast furnace (*C.R.* 62, 891).

By means of these various forms of apparatus the dissociation of the following gases was demonstrated:—

an accidental phenomenon connected with the rapid heating and cooling of portions of the gas. J. J. Thomson (*P. M.*, June 1883) has, however, given good reason for believing that decomposition is a necessary condition for the passage of electrical discharges; that in fact a spark can no more pass through an atmosphere of water-vapour without resolving it partially into oxygen and hydrogen than an electric current can pass through copper sulphate solution without decomposing it into copper and sulphuric acid. Whether Faraday's law of electrolysis extends to gases is still an open question; the probability is that it does not. However the decomposition is produced, there will probably be a certain amount of recombination as soon as the gases cool sufficiently. Since the products of decomposition are in general diluted with a large proportion of undecomposed gas, the temperature of the decomposed portions will often fall below the minimum temperature of combination before complete recombination has had time to take place. This will leave a balance of decomposition at each spark. As soon, however, as the products of decomposition have accumulated to a small extent, they, as well as

FIG. 1.

Water vapour by I. and II.—Carbon dioxide by II.—Carbonic oxide by III.; carbon deposited on the tube.—Sulphur dioxide by III.; tube blackened, and deposit of sulphur trioxide on it.—Hydrochloric acid by III.; surface of tube being previously amalgamated, and chloride of mercury and silver formed by the dissociation.

It will also be convenient to notice here the dissociation of gases produced by electrical discharge. There is no real difference between the spark discharge and the so-called silent discharge. The silent discharge is merely a spark discharge in which the sparks are very numerous and very small. In the cases where a limit has not been observed, the explanation is to be found in the fact that one or more of the products of decomposition is either liquid or solid, and is so removed from the sphere of action. This is notoriously the case with acetylene and hydrocarbons generally. Where a limit is attained, the reaction may generally be made complete by introducing a substance capable of absorbing at least one of the products of decomposition. It was formerly believed that the decomposition of gases by electric sparks was, so to speak, merely

the undecomposed gas, will be acted on by the spark, and a certain amount of recombination will take place. It must be noted, however, that the decomposition produced by each spark is very small, since the energy of the electric field is in general small compared with the amount of energy required to produce even a small decomposition. After a certain length of time the decompositions and recombinations will become equal, and the limit of the reaction will be attained. The production of a limit in the experiment of ozonising oxygen is well known, and the production of ozone at all shows that oxygen molecules must be previously electrolysed into oxygen atoms. This is also proved by an experiment of De la Rue and Müller, repeated and modified by Thomson and Threlfall, whereby a large increase of volume is observed to take place in a tube through which a spark passes, and which is much greater than can be accounted for by the expansion due to heating. In oxygen, if the sparks are very small so that the heating is insignificant, a diminution of volume is observed to take place owing to the production of ozone. The action of the spark on gases seems

to be dependent on the nature of the spark, and this in turn depends to a great extent on the pressure of the gas. Much work still requires to be done in this direction. At present the following list of gases which have been decomposed will suffice: Oxygen, nitrogen (?), carbon dioxide, methane, ether, acetylene, ammonia, acetic acid, phosphoretted hydrogen, carbonic oxide, hydrocarbons generally, sulphuretted hydrogen, seleniuretted hydrogen, cyanogen, &c. Decomposition of the fluorides of boron and silicon and chlorine has not yet been observed, but there is little doubt that the decomposition of these bodies will ultimately be demonstrated. Most of the above observations have been made by P. and A. Thénard (*C. R.*) and by Berthelot. An account of the extremely valuable researches of Berthelot and Vieille on dissociation during explosion, as well as of the observations of Dixon, will be found in the article *Explosion*.

tures have to be made, and these are subject to the almost unavoidable experimental uncertainty attendant on that very difficult operation. A judgment as to the trustworthiness of the results obtained can in general be formed only from a study of the observer's own account of his experiments.

The methods of thermal chemistry have been applied by Berthelot to the solution of many interesting questions.

**Dissociation in non-homogeneous systems.**—We shall consider first the allotropic change produced by heat in ordinary phosphorus. When yellow phosphorus is heated in a closed space it is partially changed into red phosphorus; and when red phosphorus is heated it is partially converted into yellow phosphorus. It is found that neither reaction is complete, but that the same limit is attained whether we start from red or from yellow phos-

*Curve representing the pressures of ordinary phosphorus which limit the allotropic transformation of the phosphorus at different temperatures.*

Scales: 1 mm. for 1 mm. of vapour-pressure, and 0.2 mm. for 1 degree of temperature.

FIG. 2.

#### Quantitative Experiments on Dissociation.—

It is now our business to discuss the quantitative experiments which have been made on particular cases of dissociation. From a theoretical point of view these experiments fall into two classes:

(a) *Those made on the determination of the limit, and its dependence on pressure, temperature, &c.*

(b) *Those referring to the velocity of the reaction.*

From an experimental point of view very different methods have to be adopted in different cases. In one class of experiments the observations take the form of determinations of vapour density at different temperatures and pressures. Experiments on velocity usually depend on the ordinary methods of analysis; and of course involve observations by the chronometer. In many cases observations of high tempera-

phorus. If we start with yellow phosphorus, and heat it to a definite temperature in a closed vessel in connexion with a manometer, a transformation into red phosphorus will take place. Yellow phosphorus has a considerable vapour-pressure; the transformation will go on till the pressure inside the vessel reaches a certain value; this value will be less than the maximum vapour-pressure of red phosphorus corresponding to the temperature, and is called the 'limiting pressure.' If, on the other hand, we start with red phosphorus, the vapour-pressure will diminish from the maximum to the limiting pressure. This pressure is found to be the same in both cases, provided the temperature is the same. Analysis of the residue gives the proportions of red and yellow phosphorus. Each temperature has its definite limiting pressure. If we start with a small

quantity of yellow phosphorus, and heat it in a vessel so large that it is not able to produce the limiting pressure corresponding to the temperature, no red phosphorus will be formed. The phenomenon is, therefore, quite analogous to the vapourisation of a liquid according to the two cases when the conditions are such that the vapour is (a) saturated, or (b) unsaturated.

The accompanying curves (figs. 2, 3, 4) and numbers will give the results obtained. (The results are chiefly taken from Lemoine's *Études sur les Équilibres Chimiques*.)

Ordinary phosphorus introduced into a space of one litre.

Quantities of ordinary phosphorus persisting at 440° at the end of:

Grams.	5m.	1h.	2h.	8h.	17h.	24h.	32h.	41h.
gr.	gr.	gr.	gr.	gr.	gr.	gr.	gr.	gr.
2.9 (Lemoine)	—	—	—	2.9	—	—	—	—
5.2 id.	—	—	—	5.3	—	—	4.9	4.7
16.0 id.	—	—	—	5.0	—	—	—	—
24.0 (Hittorf)	15.8	11.1	7.0	4.4	—	—	—	—
30.5 (Lemoine)	—	5.4	4.0	3.7	3.6	—	—	—

The common limit is 3.6 gram.

Curves representing the weights of ordinary phosphorus remaining at the end of different times, for a similar weight *P* of ordinary phosphorus introduced (Lemoine).

FIG. 3.

FIG. 4.

We may account for these same differences by calculating, according to the preceding data, the mean quantity of red phosphorus produced in one hour:—

Ordinary phosphorus introduced per litre.      Red phosphorus formed in grams in one hour at 440°.

grms. 5.9 30.0	Time.			
	from 0 to 2h. from 2 to 8h.		from 8 to 32h.	
	←	0.075	→	0.015
	12.30	0.233	0.015	

Temperature 440°.

Red phosphorus employed per litre.	Quantities of ordinary phosphorus in grams produced at the end of:							
	1h.	2h.	8h.	23h.	32h.	39h.	47h.	83h.
1.8 . . . .	—	0.80	1.33	—	—	1.7	—	—
4.9 . . . .	—	1.62	2.9	—	—	3.3	—	3.32
16 . . . .	—	3.67	4.8	—	4.0	—	—	—
30 . . . .	4.54	4.75	4.4	3.9	3.74	—	3.72	—
100 . . . .	—	—	4.3	—	—	—	—	—
1000 . . . .	—	—	3.97	—	—	—	—	—

It will be noticed that in some of the velocity experiments, starting from red phosphorus, the vapour-pressure at first produced is higher than the pressure of the limit; this is explained by the previous history of the red phosphorus, of which it appears there are several allotropic modifications depending on the temperature at which they have been produced. This has been studied by Troost and Hautefeuille and completely explained.

Cyanogen is slowly transformed into paracyanogen on heating. The velocity is very small, but appears to be greatest at about 500°. The inverse reaction has a comparatively great velocity. There is a limiting pressure of transformation just as in the case of phosphorus. Observations are complicated by a continual slow decomposition of the cyanogen into nitrogen and carbon. An analysis has, therefore, to be made of the residue before the correct limiting pressure can be obtained. The following are the numbers of Troost and Hautefeuille:

Temperatures	Pressures of the cyanogen in mm.
502°	54
506	56
559	123*
575	123*
587	157
599	275*
601	318
620	868*
640	1310

The numbers with asterisks have been obtained with paracyanogen prepared from cyanide of silver. The others have been furnished by paracyanogen prepared from cyanide of mercury, and perfectly freed from the metal.

Cyanic acid is converted into cyanamide and vice versa. The velocity depends on the temperature; and it is by no means the same for the two reactions. A complication is introduced, because above 150° gaseous cyanic acid is transformed into solid cyanic acid; and below 150° cyanamide is produced. The production of a maximum vapour-pressure limiting the decompositions is perfectly clear and definite. The numbers are—

Temperatures	
160°	170 180 195 215 227 251 330 350
Transformation-pressures	
56mm.	68 94 125 157 180 285 740 1200

Allotropic transformations of homogeneous systems. *Acetic acid.* The vapour of acetic acid has long been known to possess a vapour density greater than the theoretical density. This diminishes, however, as the temperature rises, or, in other words, the coefficient of expansion of acetic acid vapour between certain temperatures is greater than it is for most gases. A discussion of the explanations advanced to account for this has been already given. The data for the dissociation of acetic acid are given on p. 394 (Ramsay & Young, *C. J.* 49, 790).

*Nitrogen tetroxide* (Deville and Troost, *C. R.* 64, 237). The relation between the vapour-density and temperature of nitrogen tetroxide under ordinary pressures shows that at about 150° the change of tetroxide into a gas of the molecular formula  $\text{NO}_2$  is complete. The numbers are as follows:—

Dissociation of nitrogen tetroxide  $\text{N}_2\text{O}_4$ . Sp. gr. of  $\text{N}_2\text{O}_4 = 3.18$ ; of  $\text{NO}_2 + \text{NO}_2 = 1.59$ ; (air = 1).

Temp.	Sp. gr. of gas	Percentage dissociation	Mean increase in percentage dissociation for 10° rise of temperature
26.7°	2.65	19.96	6.5
35.4°	2.53	25.65	8.1
39.8°	2.46	29.23	11.0
49.6°	2.27	40.04	12.1
60.2°	2.08	52.84	13
70°	1.92	65.57	10.4
80.6°	1.80	76.61	8.8
90°	1.72	84.83	4.4
100.1°	1.68	89.23	3.1
111.3°	1.65	92.67	3.5
121.5°	1.62	96.23	1.8
135°	1.60	98.69	
154°	1.58	100	

Troost, continuing the experiments in 1878 at very low pressures, finds that at temperatures as low as 27° complete dissociation may take place.

Naumann gives a large series of numbers, as in the case of acetic acid vapour, between temperatures of -6° and +22.5° and pressures of 84 to 301 mm. Another determination of the density of nitrogen tetroxide vapour has been made with extreme care by E. and L. Natanson (*W. A.* 1886. 164).

As has been already stated, Berthelot and Ogier have measured the specific heat of acetic acid and nitrogen tetroxide vapours. The method adopted was Regnault's; care was taken in the case of nitrogen tetroxide to have all the apparatus made of glass. The specific heats were of course measured under constant pressure. Through the range of temperature over which it undergoes change, the specific heat is enormously greater than the mean specific heat of permanent gases formed from their elements with condensation. For the latter Regnault gives, for nitrous oxide, for instance;

Molecular specific heat  $8.76 + .0055t$   
And for carbon dioxide  $8.23 + .01177t$ ,

while for gases formed without condensation we have practically the same value without a temperature-coefficient, at least up to 200°. For some organic substances the specific heats are much greater. Wiedemann gives as follows:—

formulas I, and I respectively. Considering the rate of dissociation and its relation to pressure we may say that the rate of dissociation per degree of temperature becomes greater as the pressure diminishes. These changes are accompanied by a change of the absorption-spectrum (Salet, *Bl.* 1873. 674).

#### Dissociation of compounds.

##### I. Systems that are not homogeneous.

##### Carbonate of calcium.

*Bibliography.*—Debray (*C. R.* 64, 603); Weinhold (*P.* 149; *J.* 1874. 119); Raoult (*C. R.* 1881. 189); Birnbaum and Maher (*Bl.* 1880. 88); Wiedemann (*P. Jubelb.* 1874. 474; *J. pr.* [2] 9, 338).

Debray made the first research on this subject. His method consisted in heating Iceland

Debray found it, and that the variations of pressure are never regular. Raoult finds that, starting with quicklime and  $\text{CO}_2$ , combination takes place with incandescence at about  $550^\circ$ . The compound formed has, however, the formula  $(\text{CaO})_x\text{CO}_2$ . This compound is capable of absorbing more carbon dioxide, though the velocity of the reaction is very small; in twelve hours after a continual passage of a stream of  $\text{CO}_2$ , over the compound, analysis shows that a body of the composition  $4\text{CaO} \cdot 3\text{CO}_2$  is produced, and an extremely slow absorption still goes on. Raoult also finds that the amount of carbon dioxide absorbed depends on the previous history of the quicklime and that it is much less absorbent if it has been previously heated to a high temperature. Wiedemann finds that much

For the acetic acid curves the temperature scale is supposed to be increased by  $100^\circ$ . The heat absorbed between  $120^\circ$  and  $260^\circ$  is divided into 100 parts, as is the change of vapour-density.

For the nitrogen tetroxide the amount of heat absorbed between  $127^\circ$  to  $193^\circ$  is divided into 100 parts, as is the dissociation as given by Naumann and Salet.

FIG. 5.

spar in a vessel connected with a manometer and air-pump; an arrangement providing for the introduction of carbon dioxide was also attached to the apparatus. Decomposition of the calcium carbonate begins at  $440^\circ$ , the crystals becoming opaque owing to changes at the surface. Above this point the phenomenon of limiting pressure depending on the temperature is observed. According to Debray the limit is the same whether we start from calcium carbonate in a vacuum, or from quicklime in an atmosphere of carbon dioxide. If in any case the pressure is kept below the limiting pressure corresponding to the temperature, the Iceland spar will be completely decomposed.

Vapour-pressure at  $860^\circ = 85$  mm. of mercury.  
 $1040^\circ = 520$  mm. "

Weinhold, repeating these experiments, finds that the pressure of  $\text{CO}_2$  is always greater than

depends on the crystals of Iceland spar selected being previously carefully dried. Debray is probably substantially correct in his general deductions, but not in his experiments.

*Hydrated salts.*—Efflorescence (Debray, *C. R.* 1868. 194). In general, the same phenomena are observed in heating hydrated salts as in heating calcium carbonate. There is a definite limiting pressure for every temperature; this is the same whether the water-vapour exists by itself or in presence of air. In fact the hydrated salts act very much like liquids in their appreciation of 'partial pressures.' The phenomena are modified in accordance with the fact that each salt is generally capable of forming more than one definite hydrate.

The numbers observed by Debray for crystallised sodium hydrogen phosphate will serve as examples. ( $\text{Na}_2\text{HPO}_4 + 24\text{H}_2\text{O}$ ) and

( $\text{Na}_2\text{HPO}_4 + 14\text{H}_2\text{O}$ ).  $f$  is maximum vapour-pressure of the salt,  $F$  is pressure of water-vapour at same temperature:—

Temperatures °	Phosphate of sodium containing from 14 to $\frac{3}{4}$ $\text{H}_2\text{O}$		Phosphate of sodium containing a little less than $14\text{H}_2\text{O}$	
	$f$ millimetres	$\frac{f}{F}$	$f$ millimetres	$\frac{f}{F}$
12.3	7.4	0.694	4.8	0.452
16.3	9.9	0.717	6.9	0.500
20.7	14.1	0.776	9.4	0.517
24.9	18.2	0.777	12.9	0.551
31.5	30.2	0.819	21.3	0.618
36.4 (the salt melted)	39.5	0.877	30.5	0.678
40.0	50.0	0.901	41.2	0.750

Wiedemann has observed the relation between limiting pressure and temperature for the following salts:—

$\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$			
Temp. °	Pressures mm.	Temp. °	Pressures mm.
24.3	17.8	50	75.7

55.2	103.5	93.5	548.9
60	131.3		

Naumann has studied the efflorescence of sulphate of copper very carefully, and it is chiefly through his researches that the influence of previous history and the precautions necessary in observing the equilibrium of slow velocity changes have been brought to light. These experiments show very clearly how the velocity depends on the state of the salt with respect to the size of its particles. In the case of crystals a slow progressive change goes on as the inner portions become dehydrated, and it is only when

Curve representing the density of iodine vapour at different temperatures and at different pressures according to the experiments of Crafts and Meier (Lemoine).

Scales: 8 mm. to 100 degrees, 12.35 mm. to 1.0 of variation of density.

FIG. 6.

the composition of the crystals is uniform throughout that the equilibrium is obtained.

*Carbonates of manganese and silver* (Joulin, *A. Ch.* 1873. 276).—The velocity of the reaction is very slow; and the influence of the previous history is even more marked than in the case of carbonate of lime, so much so that the author considers that allotropic modifications of the salts exist, and that these have different vapour pressures. Carbonate of silver appears to be even more irregular in its behaviour than carbonate of manganese. Lemoine has summed up these experiments as follows. After laying down the simple principles as deduced from experiments on carbonate of lime he says: 'Mais

*Oxide of iridium* (H. St. C. Deville and Debray, *C. R.* 1878. 441).—A clear example of dissociation. Limit at  $823^{\circ}$  is 5 mm., and at  $1189^{\circ}$ , 745 mm. At  $1000^{\circ}$  the limiting pressure is greater than the partial pressure of oxygen in the air at atmospheric pressure; it follows from this that at temperatures below  $1000^{\circ}$  the iridium oxide can decompose in air, and at temperatures above this iridium is non-oxidisable.

*Compounds of metallic chlorides with ammonia*, studied by Isambert (*C. R.* 1878).—The curves (taken from Lemoine) will suffice to explain the matter sufficiently (fig. 7).

*Chloride of sulphur*, and the compound formed by the combination of cuprous chloride

Curves representing the pressures of ammonia-gas which limit the dissociations of ammoniacal chlorides at different temperatures.

FIG. 7.

Il peut se présenter des cas où la combinaison, tout en se faisant en même temps que la décomposition, soit si lente que toutes sortes de circonstances accidentelles influent sur elle: il peut se faire que les éléments mis en liberté éprouvent des modifications allotropiques, au moins commençantes, qui gênent leur combinaison nouvelle. Dans tous ces cas, l'établissement d'une tension limite, tout en étant l'expression générale du phénomène, se manifestera moins nettement, parce que la loi est compliquée par différentes circonstances accessoires.

*Mercuric oxide* (Myers, *Bt.* 1871).—The experiments are so complicated by the vapour of mercury set free that no useful information has yet been drawn from them.

and carbonic oxide, appear to dissociate, and have given rise to some discussion (Berthelot, *A. Ch.* [3] 46, 48; Michaelis, *A.* 170; Isambert, *C. R.* 1878).

*Metallic hydrides* (Troost a. Hautefeuille, *C. R.* 1874 a. 1875).—These researches have shown that hydrogen may be associated with metals in three different ways:—1. By simple condensation as in the well-known case of platinum black. 2. By solution. 3. By chemical combination. Heating the substance in a closed space in connexion with a manometer and air-pump will at once show which of the three forms of combination is exhibited in any special instance. If the gas is simply condensed there will be no definite relation between the

pressure and the temperature. It generally happens that the second and third order of phenomena are exhibited together. In this case the gas that is dissolved will be simply evolved on heating, and will leave a more or less definite compound having a definite limiting dissociation pressure.

For instance, *potassium hydride*  $KH$  'dissolves' forty times its volume of hydrogen, so that on heating and exhausting this gas is evolved. It would probably, however, be more accurate to say that two or more hydrides may be formed of different degrees of stability. On raising the temperature we get a definite dissociation of the potassium hydride which remains. The numbers are:—

Temperatures °	Pressures of dissociation mm.	Temperatures °	Pressures of dissociation mm.
330	45	390	363
340	58	400	548
350	72	410	736
360	98	420	916
370	122	430	1,100
380	200		

*Palladium hydride* gives:

Temperatures °	Pressures of dissociation mm.	Temperatures °	Pressures of dissociation mm.
20	10	120	467
40	25	140	812
60	50	160	1,475
80	106	170	1,840
100	232		

The compound formed by chlorine and water dissociates very readily, giving the curve shown in fig. 8.

*Hydrogen selenide*.—The dissociation of this gas has been studied by Ditte (*C. R.* 1872. 980). It apparently presents the extraordinary anomaly of the dissociation-pressure not increasing continuously with the temperature. It must be noted, however, that below the temperature of  $270^{\circ}$  the velocity of the reaction is so small that the composition of the gaseous mixture has to be determined by a sudden cooling of the sealed tubes containing the gas, and a subsequent analysis of their contents. It may be very fairly asked how, in the first place, this

*Dissociation of chlorine hydrate.*

Scales: 5 mm. for one degree of temperature, 5 mm. for 100 mm. of pressure.

FIG. 8.

And for *sodium hydride*, in which hydrogen is much less soluble, the numbers are:—

Temperatures °	Pressures of dissociation mm.	Temperatures °	Pressures of dissociation mm.
330	28	390	284
340	40	400	447
350	57	410	598
360	75	420	752
370	100	430	910
380	150		

procedure gets over the velocity difficulty, and, in the second place, whether it is likely to give any information at all seeing that no cooling can take place in an infinitely short time. The following numbers will give an idea of the velocity of the reaction when selenium is heated with hydrogen:—

Temperature of $350^{\circ}$ .			
Number of hours	Proportion per 100 of $H_2Se$ formed	Number of hours	Proportion per 100 of $H_2Se$ formed
10	31.4	63	87.8
24	33.1	74	87
25	34.2	96	87.8
44	36.6		

## Temperature of 440°.

Number of hours	Proportion per 100 of H <sub>2</sub> Se formed	Number of hours	Proportion per 100 of H <sub>2</sub> Se formed
15	45.8	69	50.6
21	48.8	165	51.5

The effect on the velocity of changing the pressure of the hydrogen is small, and acts so as to diminish the velocity when the pressure increases; but the limit of the reaction was probably never attained in these experiments. The effect of porous bodies has also been studied by Ditte, and the result is that a small but definite increase of velocity is due to their action, which is less marked, however, at high than at low temperatures.

*Ammonia and carbon dioxide* (Naumann, A. 84; Horstmann, A. 1887).—The limiting pressures of dissociation of ammonium carbamate are given by Naumann as follows:—

Temperatures °	Pressures of dissociation mm.	Temperatures °	Pressures of dissociation mm.
-15	2.6	26	97.5
-10	4.8	30	124
-5	7.5	36	191
0	12.4	40	248
6	22	46	354
10	29.8	50	470
16	46.5	55	600
20	62.4	60	700

The velocity is small and increases with the temperature; it also largely depends on the extent of surface exposed by the carbamate.

Naumann and Horstmann have studied the effect of the presence of an excess of ammonia or carbon dioxide. They find that the effect of an excess of either gas is to hinder the dissociation. In other words, the limiting pressure is diminished by the presence of an excess of either gas. This does not appear to be the same for the same excess of either gas. With a given excess the limiting pressure is greater in carbon dioxide than in ammonia.

## Case in which carbon dioxide is in excess:—

Temperature °	Total pressure observed after mixture	Partial pressure of the gas added in excess	Difference $P - \pi = p_1$	Vapour-pressure of the carbamate in a vacuum at temperature considered	Ratio $\frac{P}{p}$	Ratio $\frac{p_1}{p}$
20.4	78.9	33.5	45.4	66.2	0.52	0.71

II. *Dissociation in homogeneous systems.*—Theoretically by far the simplest cases; numerical results are, however, obtained with greater difficulty than in the cases last considered.

*Amylene bromide* (Wurtz, C. R. 60, 729).  $C_6H_5Br$  dissociates when heated into amylene and hydrobromic acid; the dissociation is complete at 360°. Wurtz measured the thermal changes produced by mixing amylene vapour and hydrobromic acid, and found that at 360° the change was zero, and became increasingly positive as the temperature fell (C. R. 72). Here then we have for the second time a proof of dissociation; the heat of combination of amylene and hydrobromic acid bears a simple relation to the amount of dissociation as deduced from the vapour density observations. Want of agreement, however, was noticed in some experiments, and attributed by Wurtz to the limit not being obtained in all cases since the velocity is small.

*Phosphorus pentachloride*  $PCl_5$ . Owing to the researches of Wurtz on the vapour density of this body we may consider that, subject to the application of Avogadro's law, dissociation has in this case been demonstrated. The primary object of Wurtz's experiments was to find whether the vapour of phosphorus pentachloride conformed to the law of Avogadro; assuming this to be the case, it follows that dissociation must take place in the observed cases of anomalous vapour density. Applying the principle

of the action of mass, Wurtz hit on the notion of measuring the vapour density of the pentachloride when it was vapourised into an atmosphere of phosphorus trichloride vapour. From the analogy of other experiments the effect of the trichloride should be to prevent dissociation, supposing it to take place under ordinary circumstances. This was found to be the case, and thus it was proved that phosphorus pentachloride does obey Avogadro's law; or if we assume that Avogadro's law expresses the very nature of the gaseous state under all circumstances whatever, then the dissociation of the pentachloride under ordinary circumstances may be considered to be demonstrated.

The experiments of Cahours were made at ordinary pressures; of Wurtz and of Troost and Hautefeuille at low pressures; the low pressures were produced by Wurtz by the method of mixing air with the vapour, and by Troost and Hautefeuille directly by means of a 7 air-pump. The numbers are:—

*Experiments of Cahours at atmospheric pressure.*

Temperatures	Vapour Density	Ratio $\frac{x}{1-x}$ of $\text{PCl}_5$ combined to $\text{PCl}_3$ possible	Ratio $\frac{1-x}{x}$ of $\text{PCl}_5$ dissociated to $\text{PCl}_3$ possible

*Experiments of Troost and Hautefeuille.  
Low pressures obtained directly by a partial vacuum.*

Temperatures	Pressure of the vapour	Density of the vapour of the per-chloride	Ratio $\frac{x}{1-x}$ of $\text{PCl}_5$ combined to $\text{PCl}_3$ possible	Ratio $\frac{1-x}{x}$ of $\text{PCl}_5$ dissociated to $\text{PCl}_3$ possible
°	mm.			
144.7	247	6.14	0.82	0.18
148.6	244	5.964	0.79	0.21
150.1	225	5.886	0.77	0.23
154.7	221	5.619	0.72	0.29
167.6	221.8	5.415	0.67	0.33
175.8	253.7	5.235	0.62	0.38
178.5	227.2	5.150	0.60	0.40

The results of Troost and Hautefeuille are probably the best, because there is reason to suppose that the limit was not always reached by Wurtz, and he had no right to treat the vapour as accurately fulfilling the law of Boyle.

Lemoine has calculated the influence of an excess of trichloride vapour from the experiments of Wurtz and Cahours.

*Hydriodic acid* (Lemoine, C. R. 1875 and 1877; A. Ch. 1877).—Hydriodic acid was chosen by Lemoine as the subject of an exhaustive series of experiments for the following reasons. The chemical constitution of hydriodic acid is the simplest possible for a compound; the products of its dissociation are gaseous at manageable temperatures, and the thermal changes undergone during dissociation are very small; the velocity of the changes is large enough to be manageable.

*Velocity of formation or decomposition of hydriodic acid* varies enormously with the temperature. At 440° equilibrium is restored almost in an hour; at 350° days are required; while at 260° the period is one of months. The decomposition of hydriodic acid at 260° appears to be much slower than the combination of hydrogen and iodine vapours.

*Relation of free to total hydrogen at the end of 8 hours, beginning with (a) hydriodic acid, (b) mixture of hydrogen and iodine.*

Temperatures	Hydriodic acid	Mixture of hydrogen and iodine
350°	0.03	0.69
440°	0.22	0.25

Again, the velocity depends on the pressure, being greater the greater the pressure. Thus, at the end of 8 hours—

At a pressure of 4 atmospheres 0.44 free, leaving 0.56 combined.

At a pressure of 2 atmospheres 0.69 free, leaving 0.31 combined.

At a pressure of 1 atmosphere 0.97 free, leaving 0.03 combined.

At the end of 34 hours we shall have—

At a pressure of 4 atmospheres 0.29 free, leaving 0.71 combined.

At a pressure of 2 atmospheres 0.48 free, leaving 0.52 combined.

At a pressure of 1 atmosphere, 0.61 free, leaving 0.39 combined.

The relation of velocity to pressure is rendered clearer by the curves shown in figs. 9, 10, and 11.

The horizontal lines represent the time in days. The vertical lines represent the relation of the free hydrogen to the hydrogen introduced (free hydrogen persisting if we begin with iodine and hydrogen; set at liberty if we start with hydriodic acid).

The value of the limit varies with the temperature and pressure, but varies much less than the velocity. The variation appears to be regular. The effect of pressure is very small but real, and more marked at high temperatures than at low ones. Compression appears to make combination more complete. \* Special care was taken to insure the attainment of the limit. A small correction has to be made for the action on the glass, this has been determined experimentally and found to make the corrected value of the limit greater than the uncorrected value: a very curious result. The ratio of free to total hydrogen at 4.5 atmospheres is increased about 4 p.c., and at 9 atmospheres about 14 p.c., but these actual values can hardly be considered quite satisfactory. The curve shown in fig. 12 indicates the relation between the limit and the pressure.

*Hydrogen and iodine vapour heated to 440° in variable proportions, the pressure remaining constant (Lemoine).*

Duration of the experiment in hours	Pressure at 440° of the hydrogen alone atm.	Ratio of the equivalents of iodine and hydrogen	Ratio of free to total hydrogen.

Hydriodic acid (ascending curve).

FIG. 10.

The ordinates marked by points represent the relation of the free hydrogen to the total hydrogen calculated when the action of the glass is neglected; the ordinates marked by crosses represent the same relation, taking this action into account, for eight hours' heating.

Excess of one of the elements has the same effect as diminishing the pressure as far as velocity goes, that is, velocity diminishes with an excess of either element.

The influence on the value of the limit is much more marked. 'An excess of either element gives stability to the compound.' This is shown by the curve (fig. 13) and the following table:—

Vol. II.

hydrogen combined, and consequently also the volume of iodine vapour combined; the volume of iodine vapour introduced =  $Ar + rq$  (since  $AB$  is inclined at 45 degrees);  $mq$  is therefore the volume of iodine uncombined. The ratio of the hydriodic acid dissociated to the hydriodic acid possible is therefore that of the lines  $mq$  and  $rq$ . If all the iodine combined, the curve would be reduced to the straight line  $AB$ . If with an infinitely small quantity of iodine there was no dissociation, the curve would be tangential to  $AB$ ; this, however, does not occur.

We may take from the curve the ratio of the hydriodic acid dissociated to the 'possible' hy-

D D

driodic acid, that is to say, the amount of hydriodic acid which would be formed were all the iodine taken up by the hydrogen. In the case where the temperature is  $440^{\circ}$ , and the partial pressure of the hydrogen is 2.3 atmospheres, we get the following:—

Ratio of the number of equivalents of iodine and hydrogen	Ratio of HI dissociated to HI possible	Ratio of HI persistent to HI possible
1.000H + I	0.24	0.76
1.000H + 0.784I	0.17	0.83
1.000H + 0.527I	0.14	0.86
1.000H + 0.258I	0.12	0.88

Again, if we cause 1 equivalent of iodine to act respectively on 1, 2, 3, &c., equivalents of

alter the velocity enormously, but have only a small influence on the limit. The action of sunlight appears in some cases to destroy the limit entirely, and to cause perfect combination.

*Methyl ether and hydrochloric acid* (Friedel, C. R. 81).—When a mixture of methyl ether and hydrochloric acid is passed through well-cooled tubes a liquid is formed whose composition is variable, and may be considered to be represented by the formula  $x(\text{CH}_3)_2\text{O} + y\text{HCl}$ . If the gases are merely mixed a dissociable system is obtained, behaving in many ways like the one last considered, but differing from it in that a contraction of volume takes place during the combination of the ether with the hydro-

Pressure = 1 atmosphere.  
Hydrogen and iodine.

FIG. 11.

Curve representing the relation of the free hydrogen to the total hydrogen, that is to say the limit of decomposition of hydriodic acid, at  $440^{\circ}$  for different pressures.

FIG. 12.

hydrogen, we get the following relations, which may be put in a curve (fig. 14):—

Composition of the system introduced.	Ratio of HI dissociated to HI possible	Ratio of HI persistent to HI possible
H + I	0.26	0.74
2H + I	0.16	0.84
3H + I	0.13?	0.87
4H + I	0.12	0.88

Lemoine considers it probable that an indefinite increase of one of the reacting bodies would never tend to produce total combination of the other. Berthelot doubts this.

Porous bodies, and especially platinum black,

chloric acid. This facilitates observation, but makes the application of theory more difficult. The velocity of the reaction is so great as to be unobservable.

The condensation amounts to one-half the volume of the mixed gases.

Vapour density of	oxide of methyl is	1.592
" "	hydrochloric acid is	1.263
" "	compound if completely formed is	2.851
" "	mixture of equal volumes of methyl oxide and HCl is	1.43

I. *Rise of temperature* increases dissociation. Numbers are:—

	Vapour density
If the combination be total . . . 5° . . .	2.884
At the temperature of . . . 15° . . .	1.645
" " . . . 25° . . .	1.570
" " . . . 35° . . .	1.537
" " . . . 45° . . .	1.516
" " . . . 55° . . .	1.506
" " . . . 65° . . .	1.498
" " . . . 75° . . .	1.488
" " . . . 85° . . .	1.474
" " . . . 95° . . .	1.467
If the decomposition be total . . .	1.430, or 1.442

with the gaseous mixture employed by Friedel.

II. *Influence of pressure.*—Dissociation diminishes with increasing pressure, thus:—

	Vapour density
If the decomposition were total . . .	1.430
At the pressure of 670mm. of mercury . . .	1.537
" " 750 " . . .	1.548
" " 850 " . . .	1.565
" " 950 " . . .	1.583
" " 1050 " . . .	1.602
" " 1100 " . . .	1.611
If the combination were total . . .	2.854

III. *Influence of an inert gas*, such as air, is the same as that of a reduced pressure.

Curve representing the ratio of free hydrogen to total hydrogen in a mixture of hydrogen and iodine vapour heated to 440° in variable proportions.

FIG. 13.

Curve representing the ratio of the hydriodic acid dissociated to the hydriodic acid possible in a gaseous system, in which one equivalent of iodine vapour is heated to 440° in presence of variable quantities of hydrogen.

FIG. 14.

## DISSOCIATION.

IV. *Effect of excess* is the same as for hydriodic acid. When the temperature is about  $20^\circ$  and the pressure 1 atmosphere, the numbers are the following:—

Excess of oxide of methyl (with respect to the total volume of the mixture)	Contraction (with respect to double the volume of the less abundant gas)
= 0	= 5.8
0.10	7.7
0.20	8.9
0.40	10.8
0.60	11.8

Excess of hydrochloric acid  
(with respect to the total  
volume of the mixture)

= 0	5.8
0.10	7.7
0.20	8.6
0.40	10.4
0.60	11.2

These may be put in a curve thus:—

By a simple calculation the fraction of dissociation may be obtained from the vapour-density observed. If  $y$  is the weight of compound dissociated, and  $p$  is the total weight per litre,

we find that the fraction  $\frac{y}{p}$  may be calculated from the equation  $\frac{y}{p} = \frac{2.88}{d} - 1$ , where  $d$  is the observed vapour-density. Thus the influence of temperature is given by the numbers:—

Temperature	ratio $\frac{y}{p}$ dissociated at different temperatures
$5^\circ$	0.75
15	0.84
25	0.88
35	0.90
45	0.92
55	0.93
65	0.94
75	0.95
85	0.96
95	0.97

*Curve representing the contraction of a mixture of hydrochloric acid and oxide of methyl, in which one of the two gases is in excess.*

Scales: 17 mm. for a contraction of 10 per cent. with respect to double the volume of the less abundant gas;  
7.5 mm. for 0.1 of one of the gases in excess in a volume of the mixture equal to 1.

FIG. 15.

*Curve representing the fraction of dissociation  $\frac{y}{p}$  in a mixture of hydrochloric acid and oxide of methyl, when one of the bodies is in excess.*

Scales: 5 mm. for 0.1 of the possible combination dissociated; 7.5 mm. for 0.1 of one of the gases in excess in a total volume of the mixture equal to 1.

FIG. 16.

The influence of pressure is given by the numbers:—

Pressure mm.	Ratio $\frac{V}{P}$ dissociated at the same temperature and at different pressures
670	0.88
750	0.86
850	0.84
950	0.82
1,050	0.80
1,100	0.79

When the combination takes place between two gases, of which one is in excess, the reduction is more complicated. However, it is not difficult, and is given by Lemoine, page 89 of his book. The effect of an excess expressed in this way is given by the following numbers, and in the curve, fig. 16:—

*Oxide of methyl in excess.*

Excess with respect to the total volume of the mixture	Contraction with respect to double the volume of the less abundant gas	Excess $\mu$ expressed in gas equivalents	Fraction of dissociation $\frac{V}{P}$
0	0.058	0	0.884
0.10	0.077	0.222	0.846
0.20	0.089	0.500	0.822
0.40	0.108	1.333	0.784
0.60	0.118	3.000	0.764

*Hydrochloric acid in excess.*

0	0.058	0	0.884
0.10	0.077	0.222	0.846
0.20	0.086	0.500	0.828
0.40	0.104	1.333	0.792
0.60	0.112	3.000	0.776

The calculations involve an assumption of the applicability of Boyle's law, which is, however, only justifiable in a limited degree, especially with respect to the ether vapour.

Amongst other dissociable systems which have been more or less studied we may notice

*Calomel*, by Debray (*C. R.* 83, 30).

*Ammonium chloride*, by Deville (*Leçons*); Pebal (*A. Ch.* [3] 77, 93); Marignac (*Bil.* 1867. vol. 2).

Pebal's researches have been already commented on.

*Ammonium sulphide*.—Among others, by Bineau (*A. Ch.* 70, 26); Deville and Troost (*C. R.* 56, 891; 88, 1239); Horstmann (*A. Suppl.* 1863); Salet (*C. R.* 86, 1080); Mortessier a. Engel (*C. R.* 1879).

*Chloral hydrate*.—The subject of much discussion by Troost, Wurtz, Deville, Berthelot, Naumann, &c. Remarkable for an ingenious test introduced by Troost to determine the presence or absence of water-vapour, as well as its pressure, in the vapour of chloral hydrate. The method consists in exposing hydrated salts of known vapour-pressure to the action of the vapour and observing whether they become more or less hydrated. This method, however, appears troublesome in practice, and has hitherto led to contradictory results (v. Lemoine, *Études*, 93).

*Dissociation of salts in solution v. SOLUTION.*

*Dissociation produced by electrical agency*  
A rough and provisional theory has already been given of the action of the electrical discharge in producing dissociation.

*Methods employed.*

I. A series of sparks may be caused to pass between the terminals of a eudiometer-tube containing the gas to be experimented on. In this case care must be taken to prevent the heating of the terminals, otherwise the rise of temperature produced in their neighbourhood will influence the effects to be observed in an unknown manner.

II. The most powerful arrangement yet devised is the apparatus of Siemens. This consists essentially of two concentric glass tubes; the outer surface of the larger tube and the inner surface of the smaller tube are both coated with some conducting material. The gas to be experimented on passes through the annular space between the two glass tubes. Let the two conducting surfaces be kept at different potentials; then it can be shown that there will be an electrical distribution over the surfaces of discontinuity of the dielectric. That is, there will be a distribution over the inner surface of the outer tube, and over the outer surface of the inner tube. The difference of potential between these two surfaces will increase as the difference of potential between the conducting surfaces increases. A point will finally be reached when the difference of potential of the distribution between the glass surfaces becomes sufficient to produce a breaking down of the insulation of the dielectric, and an ordinary discharge will be the result. The electric field in the instruments generally sold is fairly uniform, and the apparent electric strength of the insulating layer of gas is proportionately large. The discharge, when it does take place, consists of an enormous number of small sparks. It is to this fact that the efficiency of the apparatus is doubtless to be traced.

*Ozone*.—The subject of many experiments. Hautefeuille and Chappuis (*C. R.* 1880) give the following numbers, for the proportion of ozone formed, as representing the limits at different temperatures and pressures:—

*Proportion of ozone by weight.*

Pressure	−23°	0°	20°	100°
760 mm.	0.214	0.149	0.106	
380 "	0.204	0.152	0.125	0.0117
300 "	0.201	0.153	0.112	
225 "	0.191	0.153	0.104	0.0118
180 "	0.181	0.137	0.089	

The slow resolution of the mixture of ozone and oxygen produced in any of these experiments into pure oxygen would form a convenient field for experiments on velocity. A certain number of such experiments has been made by Berthelot (*C. R.* 1880):—

	Proportion of ozone
At the commencement	5.3
After 1 day	2.9
2 days	2.1
6 "	1.2
14 "	0.4
51 "	traces
60 "	zero

**Nitrogen and Oxygen.**—May be caused to combine under the influence of the electric spark. This experiment is chiefly interesting historically.

**Nitrogen.**—It has already been pointed out that the efficiency of the spark in producing dissociation of an observable character will depend greatly on the form of the discharge. This is a very obscure subject and cannot be treated here. The reader is recommended to consult a paper by J. J. Thomson on the electric discharge in gases (*P. M.* 1883). It is there shown that the pressure must exercise a very important influence on the phenomena to be observed.

At pressures of about 0.8 mm. a discharge of a peculiar kind obtained from an induction coil by inserting a large resistance in the circuit was observed by Thomson and Threlfall (*Pr.* 1886) to produce a contraction in an atmosphere of pure nitrogen. On heating the resulting gas the original volume was recovered. This effect probably points to the production of an allotropic form of nitrogen.

**Ammonia** forms a dissociable system: the limit is here very high: that is the ammonia may be almost completely decomposed. On the other hand, of course only a very slight combination is produced if we start from nitrogen and hydrogen, though this may be made indefinitely great by removing the ammonia formed. Some peculiar views have been put forward in this connexion by Johnson (*P. B.* 1886, No. 2; v. also Pamphlet, *Elementary Nitrogen, and on the Synthesis of Ammonia*, by Johnson [Churchill, 1885]).

**Carbon dioxide** is decomposable with a very low limit. If a bit of phosphorus be placed in the tube to absorb the oxygen as fast as it is formed the reaction becomes unlimited. The inverse case of carbonic oxide and oxygen is curious. Theoretically, from the experiments on carbon dioxide, combination should take place easily, or rather the limit should be high. However, in an experiment continued for six hours very little carbon dioxide was produced, if any. This may be accounted for if we assume the velocity of the reaction to be extremely slow, though there is no other reason for such an assumption.

**Water-vapour**, decomposed with difficulty.

**Acetylene.**—As the products of decomposition are liquid the reaction is unlimited. If the sparks are large, carbon is deposited and the reaction goes on till the gas consists of about seven volumes of hydrogen to one of acetylene. In this case there is an approximate limit. Berthelot has examined its relation to the pressure, and gives the following numbers:—

Pressure in metres of mercury	Limiting proportion of acetylene per 100 volumes
8.46	11.9
0.76	12.0 to 12.5
0.42	11.9
0.41	12.0
0.81	6.5
0.23	3.5
0.18	3.1
0.10	3.1

It will be noticed that the relation is not continuous, this is probably to be traced to the fact that the products of decomposition depend on the kind of spark employed, and this is itself conditioned by the pressure of the gas.

**Hydrocyanic acid.**—This is formed from acetylene and hydrogen by the action of the spark. The reaction is complicated by the production of other and more complex substances.

#### Theories of Dissociation.

A. Theories which endeavour to account for the phenomena of dissociation and give results, numerically comparable with experiment, based on the principle of the *action of mass*; Lemoine, Guldberg a. Waage, Van 't Hoff.

B. Theories based on the *kinetic theory of gases*; Clausius and Lemoine.

C. Theories based on the generalisation of the *principles of thermodynamics*; Willard Gibbs, Horstmann, Peslin, Van der Waals.

D. Theory based on the *vortex-atoms hypothesis*; J. J. Thomson.

E. Theory deduced from general equations of dynamics; J. J. Thomson.

**THEORY OF THE ACTION OF MASS SIMPLY** (Pfaundler and Lemoine).—Let two gases A and B in a system be in circumstances permitting combination. Let there be N molecules of A, and N' molecules of B, in a certain closed space. Other things being equal, the chance of a molecule of A combining with a molecule of B will be greater the greater the number of molecules of B in its immediate neighbourhood. Similarly the chance of combination of a molecule of B will depend on the number of molecules of A in its immediate neighbourhood. If  $dy$  is the amount of combination in time  $dt$  we shall have

$$\frac{dy}{dt} = b f(N) \phi(N').$$

If we assume that the functions are identical, which amounts to supposing that an excess of either gas would have the same influence on the result, this becomes

$$\frac{dy}{dt} = b f(N) f(N').$$

If the gases do not combine in equal volumes the violent supposition is made that a combination takes place first of all by equal volumes, and that then a further combination goes on with the other volumes step by step. Taking the case of a combination of one volume of A with two of B first of all in time  $dt$  we have an amount of compound formed given by the last equation, viz.:—

$$dy = b f(N) f(N') dt.$$

This then combines with another volume of B or

$$\frac{dy}{dt} = b' f(N') f[b f(N) f(N')].$$

A further assumption, that the amount of chemical change is simply proportional to the masses in presence, reduces our first case to

$$\frac{dy}{dt} = b NN'$$

and our second to

$$\frac{dy}{dt} = bNN^2,$$

where  $b$  is a constant.

This, however, except in a few cases, is found to be insufficient to account for experimental results, and Lemoine, therefore, introduces a new constant, thereby abandoning the theory of the action being strictly proportional to the masses in presence, and writes

$$\frac{dy}{dt} = b.N^p.N'^p$$

and

$$\frac{dy}{dt} = b.N^p.N'^p$$

for the two cases respectively.

The same result may be arrived at from a study of the kinetic theory of gases. Although owing to the assumptions necessary no real knowledge can be gained from the theory in question, still it may be useful to give a summary of it here. The reader will notice the confusion between atoms and molecules.

Let  $A$  and  $A'$  be two gases tending to combine in equal volumes,  $N$  and  $N'$  the number of 'free molecules' or atoms (?) per unit volume. Let  $\lambda$  and  $\lambda'$  be the mean distances of the two kinds of molecules: then we have

$$N\lambda^3 = N'\lambda'^3 = 1.$$

We have to find the chance of combination between the molecules of  $A$  and  $A'$ . To do this Clausius assumes that two 'molecules' will combine when their centres approach to a distance smaller than  $2l$  where  $l$  is called the 'radius of chemical activity' of each molecule. The molecules of both gases are supposed to be in motion in accordance with the well-known laws of the kinetic theory, the whole of which as far as principles go is here assumed. Instead of explicitly considering the velocities of both systems, Clausius shows that matters are simplified if we consider the molecules of  $A$  at rest, and the molecules of  $A'$  endowed with a velocity of

$$u = v + \frac{1}{3} \frac{v^2}{v^2} \text{ if } v < v, \text{ and } u = v' + \frac{1}{3} \frac{v^2}{v^2} \text{ if } v' > v;$$

$v$  and  $v'$  being the velocities of mean square of the two systems. The probability of a molecule of  $A'$  'penetrating the sphere of action' of a molecule of  $A$  during its passage between two planes perpendicular to one another, and at a small distance  $S$  apart, is found by Clausius to be  $\frac{\pi l^2}{\lambda^3} S$ . During a time  $dt$ , however, a molecule of  $A'$  will go over a space  $u dt$  with respect to the molecules of  $A$  supposed to be at rest. The chance of combination during this time is therefore  $\frac{\pi l^2}{\lambda^3} u dt$ ; or substituting for  $\lambda^3$ ,  $\pi l^2 u dt NN'$ .

Therefore, the number of molecules  $-dN = -dN'$  combined in time  $dt$  is  $-NN'\pi l^2 u dt$ .

Let  $dy$  be the number of molecules of the compound formed in time  $dt$ , then we have

$$\frac{dy}{dt} = \pi l^2 u NN'$$

or collecting constants, remembering that ' $u$ ' is a function of the temperature only,

$$\frac{dy}{dt} = kNN'$$

which we got before. But we know that this formula is only approximate, and therefore we may as well admit at once that the theory is insufficient. At best, however, the idea of a 'radius of chemical affinity' is only a diagrammatic way of regarding the process of combination. If we consider the action of temperature and pressure the case is still worse, for in default of any information at all we are obliged to regard the radius of chemical activity as remaining constant when the temperature changes. This, of course, again leads to incorrect results, and, therefore,  $l$  is supposed to vary in a manner to satisfy the experiments, leaving us exactly where we were before. Again, taking Lemoine's form of expression involving the constant  $\beta$ , we find that to account for the behaviour of hydriodic acid the 'constant' has to be made to vary; thus, at a temperature of  $350^\circ$  it has a value assigned to it of  $\cdot 8$ , and at  $440^\circ$  it is reduced to  $\cdot 553$  or  $\cdot 6$  as seems most convenient. Other people (Guldberg and Waage for instance) avoid the difficulty by putting several constants in to begin with. We may also note the following hints which are given us by the kinetic theory of gases, and which do not involve any special theory of the mechanism of chemical combination. Change of combination phenomena with change of pressure ought to be slow, since the mean distances of the molecules vary inversely as the cube root of the pressure. Since the kinetic theory gives a tolerably reasonable account of the mechanical meaning of rise of temperature, any information as to what chemical combination really is will most likely be drawn from a study of the dependence of chemical action on the temperature.

The action of pressure and temperature has been investigated by Clausius, but here again special assumptions are made.

GULDBERG AND WAAGE'S THEORY OF DISSOCIATION is sufficiently indicated in the articles AFFINITY and CHEMICAL CHANGE (vol. i.; v. especially pp. 70, 73, 737, 746; v. also EQUILIBRIUM, CHEMICAL).

THEORIES BASED ON THERMODYNAMIC CONSIDERATIONS.—Certain very important ideas appear to have been put forward by Clausius in his discussion of the term 'Disgregation.' We shall have to consider them when we come to the formal theory of Horstmann. At present it will be more convenient to take a very simple case, which seems first to have been deduced at some length from Clausius' results by Peslin (*A. Ch.* 1871).

Peslin considers the case of carbonate of lime and its decomposition by heat. According to Debray the changes which take place are perfectly reversible, and Peslin applies the general equation of Clausius for reversible systems to this particular case. For information of this general kind v. Clausius' *Mechanical Theory of Heat* (translated by W. R. Brown), and Maxwell's *Theory of Heat*.

Assuming the reversibility of the reaction in question (on which point v. *supra*), we may consider a reversible engine driven by the passage of heat from a mixture of carbonic acid, carbonate of lime, and lime, in a hot vessel, to the same mixture contained in a vessel at a lower temperature.

Let  $T$  be the absolute temperature of the hot vessel.

Let  $T - \epsilon$  be the absolute temperature of the cold vessel.

Let  $u$  be the volume occupied by unit weight of calcium carbonate before dissociation;  $u'$  the volume occupied by the same weight after dissociation.

Let  $L$  be the 'latent heat' of dissociation, which in this case is positive;  $p$  is the maximum pressure of dissociation at the high temperature;  $J$  is the mechanical equivalent of heat.

Then  $u' - u$  is the volume developed by the motion of the piston of the machine during the dissociation of unit weight of substance, and  $\frac{dp}{dt}\epsilon$  is the difference of pressure on opposite sides of the piston.

The work done, therefore, during this passage is

$$(u' - u) \frac{dp}{dt} \epsilon.$$

By Carnot's principle the heat transformed into work is

$$L \left\{ \frac{T - (T - \epsilon)}{T} \right\} = \frac{\epsilon}{T} L;$$

therefore the equation of heat transformation is

$$(u' - u) \frac{dp}{dt} \epsilon = J L \frac{\epsilon}{T}$$

$$\text{whence } L = \frac{T}{J} (u' - u) \frac{dp}{dt}.$$

Now

$$u' - u = \left(1 - \frac{u}{u'}\right) u' = \left(1 - \frac{u}{u'}\right) \frac{1 + \alpha t}{\delta_0} p_0 \text{ approx.}$$

where  $\alpha$  is the coefficient of expansion, and this will be nearly that of a perfect gas, and  $\delta_0$  is the density of the carbonic acid of dissociation reduced to  $0^\circ$  and pressure  $p_0$ . Substituting this value for  $u' - u$  and rearranging, we have

$$\frac{dp}{p} = \frac{J}{p_0} \left[ \left( \frac{L \delta_0}{1 - \frac{u}{u'}} \right) \left\{ \frac{\alpha dt}{(1 + \alpha t)^2} \right\} \right].$$

Now  $\frac{J}{p_0}$  is constant:  $\frac{L \delta_0}{1 - \frac{u}{u'}}$  is nearly so,

sufficiently nearly for our present purpose where we do not intend to deal with any very great range of temperature. In fact between  $1040^\circ$  and  $860^\circ$  the expression does not change in value more than 2 per cent.

If the engine works from a pressure  $P_2$  to a pressure  $P_1$ , we have

$$\int_{P_1}^{P_2} \frac{dp}{p} = \frac{J}{p_0} \left\{ \frac{L \delta_0}{\left(1 - \frac{u}{u'}\right)} \right\} \int_{T_1}^{T_2} \frac{\alpha dt}{(1 + \alpha t)^2}$$

where  $T_2$  and  $T_1$  correspond to  $P_2$  and  $P_1$  respectively.

Solving this equation

$$\log \frac{P_2}{P_1} = \frac{J}{p_0} \left[ \frac{L \delta_0}{\left(1 - \frac{u}{u'}\right)} \right]^2 \left( \frac{1}{1 + \alpha T_1} - \frac{1}{1 + \alpha T_2} \right).$$

Now we may get all these values from experiment, and therefore choose one to calculate, say  $L$ ; and then compare with experiment. Peslin, however, uses a rougher method by considering the engine worked with steam, and taking the expression  $1 - \frac{u}{u'}$  as the same for both

water and steam on the one hand, and carbonate of lime and the products of its decomposition on the other. Regnault's value for  $L$  for water at  $69.1^\circ$  is 558.2 cal., and the comparison will be made at such temperatures that  $69.1$  is the mean of  $T_1 = 48.4$ , and  $T_2 = 89.8$ , corresponding to the vapour pressures  $P_1 = 85$  mm. and  $P_2 = 520$  mm. This gives for the latent heat of dissociation of carbonic acid, if  $\Delta_0$  is the density of steam corresponding to  $\delta_0$ ,

$$L = 558.2 \frac{\Delta_0}{\delta_0} \left\{ \frac{\frac{1}{1 + \alpha T_1} - \frac{1}{1 + \alpha T_2}}{\frac{1}{1 + \alpha T_1} - \frac{1}{1 + \alpha T_2}} \right\}.$$

Putting in values,  $L = 666.7$ ; finally comparing this with the value deduced from Favre and Silbermann's results, we find that it is 5 p.c. smaller than it ought to be. Considering the assumptions made as to the applicability of Boyle's law, &c., this is at least as good as one can expect, and may be taken as some evidence that the dissociation process in question is really a reversible operation. This example has been dwelt on at more length than it intrinsically deserves, because it affords a very instructive example of the methods pursued in theories based on thermodynamic considerations. We pass on to

HORSTMANN'S THEORY (A. 170).—Clausius has thrown Thomson's views on the degradation of energy into the following form: 'The entropy of a system will always tend towards a maximum defined by the other conditions to which the system is exposed.'

There is no reason why this should not apply to systems undergoing dissociation. During dissociation some of the changes tend to increase, and some to diminish, the entropy of the system; according to the theory, equilibrium will be attained when the entropy has arrived at its maximum value, i.e. when its variation vanishes. Clausius has introduced the term 'disgregation of a system,' and defined it as a quantity depending on the arrangement of the parts of a system, in so far as it is the value of the entropy for the state of the system which it thus defines.

'Let  $x$  be the proportion of a body expressed in molecular weights which decomposes or combines with another.' This quantity  $x$  may then be regarded as a measure of the degree of dissociation. All the other quantities which vary during dissociation may then be regarded as functions of  $x$ . Horstmann's condition of equilibrium is thus  $\frac{ds}{dx} = 0$  where  $s$  is the entropy.

Let  $Q$  be the quantity of heat which is concerned in the dissociation of an amount of the body equal to the formula weight expressed in grams; then  $Q$ , for instance in the case of hydrochloric acid, would be the heat required to dissociate 36.5 grams. To produce the reaction in ques-

tion we should require  $Qx$  units of heat. If  $T$  is the absolute temperature, and  $Z$  the disgregation of the system, we have

$$s = \frac{Qx}{T} + Z$$

and the condition of equilibrium is found by differentiation of

$$\frac{ds}{dx} = \frac{1}{T} \left( Q + x \frac{dQ}{dx} \right) + \frac{dZ}{dx} = 0.$$

As an example, we may apply this equation to the special case of a body decomposing into two others. Let there be one equivalent at the beginning of the process, and suppose there remains undecomposed at the instant considered a quantity  $x$ , then the result is to give  $r$  molecules of one and  $s$  of the other, and let  $m$  be the weight of one of the substances in excess; then the three bodies in presence are:—

$$\begin{array}{l} x \\ r(1-x) + m \\ s(1-x). \end{array}$$

If  $Z_1, Z_2, Z_3$  are the disgregations corresponding to one equivalent of each of the three states, we have

$$Z = xZ_1 + [r(1-x) + m]Z_2 + s(1-x)Z_3.$$

Suppose further that the system is one like carbonate of lime where one of the products is solid and one gaseous; then  $Z_1$  and  $Z_2$  are independent of  $x$ , and  $Z_3$  depends only on the volume available. If  $u$  is the volume of one equivalent of the gas generated, Clausius gives

$$Z_3 = Z'_3 + AR \log \frac{u}{u_0},$$

where  $Z'_3$  is the disgregation corresponding to the same mass of gas reduced to standard conditions, i.e. to a volume  $u_0$ .  $R$  is the well-known constant used by Clausius to express the gaseous laws, i.e.  $\frac{25\alpha}{a}$  where  $\alpha = 273$ ; and  $A$  is Joule's equivalent. If  $p$  is the pressure of the gas we have  $up = RT$ .

$Q$  in this case consists of two parts, of the heat taken up in producing the chemical change, and  $Q - q$  required to do external work, in this case to the extent  $Apu$  or  $ART$ .

The equation of equilibrium therefore reduces to

$$\frac{q}{T} - AR \log \frac{u}{u_0} + C = 0,$$

where  $C = Z_1 - rZ_2 - sZ_3$ , the change of disgregation which would take place if the gas had the volume  $u_0$ ; this therefore is independent of  $x$ ;  $u$  only varies as the action proceeds, and the equation therefore expresses the fact that the pressure must be determinate for the condition of equilibrium.

The method has been applied by Horstmann to calculate the pressures produced by the dissociation of amylene bromide and phosphorus pentachloride.

*Phosphorus pentachloride.*—The agreement is fairly satisfactory, as may be seen by the following curves (fig. 17) which are given by the theory; the points correspond to observations, two of which are used to calculate each curve.

Lemoine has calculated the values of  $x$  by an appropriate modification of the above equation for hydriodic acid, and finds that the agreement is within 5 p.c.

It may be noticed about this theory that if the quantity of heat absorbed or given out during

the reaction was zero, the limit would be independent of the temperature; this actually occurs very nearly in cases of etherification, and the conclusion coincides with experimental results.

A difficulty is that dissociation, according to the theory, would go on to absolute zero, while as a matter of fact it is generally supposed only to begin at a certain point. As to this it may be said that below a certain point the dissociation has hitherto avoided detection.

The influence of an excess of one constituent is extremely well and concordantly brought out by the theory. The influence of the pressure will be zero as far as the limit is concerned if no condensation or expansion occurs; as for instance in the dissociation of hydriodic acid.

FIG. 17.

No information is given by the theory as to the progress of the reaction, i.e. we get no information from it as to velocity.

THEORY OF GIBBS (*Am. S. 18*).—This theory has many points of resemblance with that of Horstmann, as will be seen by the following statement of the principles:—

1. For the equilibrium of an isolated system it is necessary and sufficient that in all the possible variations of the state of the system, the energy being maintained constant, the variation of the entropy shall be zero or negative.

2. Similarly, if the entropy be constant the variation of energy must be zero or positive if equilibrium is to be preserved.

Applying these principles to a mixture of gases obeying Boyle's law, &c., we have for the energy of the mixture

$$M_1(C_1t + E_1) + M_2(C_2t + E_2) + \dots$$

$M_1$  and  $M_2$  are the masses of the different gases.  $C_1$  and  $C_2$  are the sp. heats at constant volume.  $E_1$  and  $E_2$  are other constants, and  $t$  is the absolute temperature.

Similarly the entropy is given by

$$M_1(H_1 + C_1 \log t - a_1 \log \frac{M_1}{V})$$

$$+ M_2(H_2 + C_2 \log t - a_2 \log \frac{M_2}{V}) + \dots \dots \dots \&c.$$

Where  $V$  is the volume,  $H_1, A_1, H_2, A_2$  are constants depending on the nature of the gas such that  $a_1$  and  $a_2$  are inversely proportional to the densities.

Gibbs assumes that these equations will also apply to a system of gases in which chemical change takes place. If we consider a system in which the energy does not vary, and in which the entropy has its maximum value, then we have one case where equilibrium is established according to the principles laid down. The condition for maximum entropy comes to be the condition that no variation of entropy shall occur when the energy and volume are constants; these two conditions together will give the following:—

$$(H_1 - a_1 - C_1 - \frac{E_1}{t} + C_1 \log t - a_1 \log \frac{M_1}{V}) dm_1 \\ + (H_2 - a_2 - C_2 - \frac{E_2}{t} + C_2 \log t - a_2 \log \frac{M_2}{V}) dm_2 \\ + \dots \dots \dots \&c. = 0.$$

This equation leads to the result that when the gaseous compound is capable of being formed without condensation, the limit of dissociation will be independent of the pressure. In other cases the dissociation will be a function both of temperature and pressure. Comparisons with experiment in the two cases (hydriodic acid and methyl ether and hydrochloric acid) show that the experimental and calculated results agree very well. A comparison with nitrogen tetroxide, formic acid, acetic acid, and phosphorus chloride vapour, has been made by Gibbs; as an example of the agreement of theory and experiment, we give the following table referring to phosphorus pentachloride:—

Temperature	Pressure	Density		Authors of the experiments
		Calculated	Observed	
°	mm.			
236	760	3.610	3.656	Calours

129	170	6.56	6.63	"
129	165	6.55	6.81	"

E. and L. Natanson have discussed the theory in their paper on nitrogen tetroxide (*W. A.* April 1886).

If the thermal changes accompanying dissociation are small, then the theory indicates that the change of dissociation with temperature will be slow. No account is taken either in this theory or in the theory of Horstmann of the supposed thermal change requisite before dissociation begins; both theories would point to the occurrence of dissociation down to absolute zero.

Again these theories are not in any sense molecular. Entropy is a quantity referring to the changes of heat into work and *vice versa*, and a molecular theory to be satisfactory must obliterate the distinction between heat and kinetic or potential energy.

THEORY OF J. J. THOMSON (*P. M.* [5] 15, 427; 17, 233).—In this theory the views of Clausius & Williamson as to chemical combination are expressed in terms of the vortex-ring theory of matter. The principles and methods adopted, however, are applicable to any theory of matter, provided only that it involves the principle of discontinuity. The advantages of this theory are that, while it is as general in its application as the theories of Horstmann and Gibbs, it affords a definitely mechanical view of the mechanism by which an equilibrium may be brought about. As has been pointed out several times, any theory based on the kinetic theory of gases is open to the same objection as that theory itself, viz. that even supposing it were brought into harmony with every conceivable experiment, we should really be no further advanced in real knowledge than we are at present, since the assumptions on which it is based themselves require explanation. The vortex-ring theory, however, does not involve such assumption; its premises are merely those of dynamics, and anything we get from it is a real gain since it cannot be twisted about to save appearances.

The account of the theory as given by Thomson is so exceedingly terse that it cannot well be abstracted, and we therefore refer the student to the original papers.

In the article *EQUILIBRIUM, CHEMICAL*, will be found a treatment of dissociation-processes as special-cases of chemical equilibrium.

**DISTILLATION.** The conversion of a substance into vapour, and the condensation of the vapour into a liquid by cooling in another part of the apparatus, is called *distillation*. If the vapour is condensed to a solid the process is called *sublimation*. The object of conducting a distillation is usually to separate one body from another which vapourises at a higher temperature than the first. The name *fractional distillation* is often given to the process of separating two or more liquids by taking advantage of differences in their boiling points. When a solid body is decomposed by heat, and the products, or some of them, are condensed to the liquid form and collected, the process is called *dry*, or *destructive distillation*; for instance, when coal is strongly heated in a closed vessel, ammonia, various gaseous hydrocarbons, many liquid and solid hydrocarbons, phenol, and many other compounds, are produced.

The essential parts of all apparatus for distillation are (1) a vessel in which the substance is heated, (2) a means for cooling the products formed by heat, and (3) a receiver to retain the condensed product or products. The ordinary form of distillation-apparatus is a flask connected with a tube, which passes inside a wider tube through which a stream of cold water circulates; a small flask or other suitable vessel is used as a receiver. Various devices are employed in fractional distillation to insure as complete a separation as possible of the more volatile from the less volatile portion of the liquid distilled.

**References.**—The history of distillation is

fully treated in Kopp's *Beiträge der Geschichte der Chemie*, Stück i. 217 *et seq.*; v. also E. Wiedemann, *Zeitschr. der deutschen Morgenländischen Gesellschaft*, 32, 575. Various forms of apparatus for fractional distillation are described by Konowalow, B. 17, 1531; Wurtz, A. 93, 108; Glinsky, A. 175, 381; Linnemann, A. Ch. [8] 42, 131; Le Bel a. Henninger, B. 7, 1084; Hempel, *Fr.* 20, 502; Kreis, A. 224, 259. Papers on the theory of fractional distillation, with experimental results, will be found in C. J. 35, 544 (Thorpe), and 547 (Brown).

**DITA BARK.** Dita, the bark of *Echites scholaris*, a tree growing in the Philippine Islands, contains ditaine, accompanied by two other alkaloids, ditamine and echitenine, and by several indifferent substances echinonachin, echicerin, echitin, echitem, and echiretin (Gorup-Besanez, A. 176, 88; Jobst a. Hesse, A. 176, 326; 178, 49; 203, 144; 11, 1546; B. 13, 1841; Harnack a. Merck, B. 11, 2004; 13, 1648). It is used as a febrifuge.

Ditaine  $C_{16}H_{25}NO_2$ . *Echitamine*. [206°].

$[\alpha]_D = -28.8^\circ$  in a 2 p.c. solution in 97 p.c. alcohol.

**Preparation.**—Dita bark is boiled with hot alcohol, the extract evaporated, and the residue treated with dilute  $NH_3$  and shaken out with ether. The ether dissolves ditamine; the residue is treated with solid KOH and extracted with  $CHCl_3$ . The extract is evaporated and treated with conc.  $HCl$  aq; ditaine hydrochloride separates while echitenine remains in solution.

**Properties.**—Vitreous prisms (containing 4 aq). M. sol. water,  $CHCl_3$ , and ether, v. sol. alcohol, v. sl. sol. benzene, insol. ligroin. Strongly alkaline, except after removal of all water of crystallisation. Conc.  $H_2SO_4$  dissolves it with purple-red colour;  $HNO_3$  gives a purple-red becoming green. Decomposes NaCl, setting NaOH free. Not ppd. from its salts by  $NH_3$ . After boiling with dilute HCl its solution reduces Fehling's solution. On evaporating an aqueous solution of ditaine atmospheric oxidation takes place with formation of 'oxyditaine.'

**Salts.**— $BHCl$ : crystalline, sol. water, sl. sol.  $HCl$  aq and solutions of metallic chlorides.  $[\alpha]_D = -57^\circ$ .— $B'H_2PtCl_6$  3aq: yellow flocculent pp.— $B'HB$ : prisms.— $B'HI$ .— $B'H_2CO_3$  1½ aq: prisms or crystalline powder.—Sulphate: needles.—Picrate: golden flocculent pp.—Tannate: white flocculent pp.— $B'H_2C_2O_4$ : powder, sl. sol. alcohol, v. e. sol. water.

Ditamine  $C_{16}H_{25}NO_2$ . [75°]. Occurs in dita bark to the extent of .04 p.c. Obtained as above. Ammonia pptd. it from its solution in dilute acids as amorphous floccula. V. sol. alcohol, ether, benzene, and  $CHCl_3$ .— $B'H_2PtCl_6$ : pale golden flocculent pp.

Echitenine  $C_{16}H_{25}NO_2$ . [above 120°]. Extracted from dita bark as above; the solution of its hydrochloride is ppd. by  $HgCl_2$ , the pp. decomposed by  $H_2S$ , KOH added, and the base extracted with chloroform. Brownish, very bitter powder. V. sol. alcohol, sl. sol. water chloroform, and ether, v. sl. sol. ligroin. Alkaline to litmus. Its solutions in conc.  $H_2SO_4$  and  $HNO_3$  are violet. Its salts are amorphous.— $B'H_2PtCl_6$ : golden flocculent pp.—

**DODECYLENE GLYCOL** *c.* **DODECENE**.  
**DODECYLDENE** *c.* **DODECENE**.

**DODEGLIC ACID**  $C_{12}H_{24}O_4$ . The chief acid produced by the saponification of the train oil obtained from the bottle-nosed whale found near the Faroe Isles (Scharling, *J. pr.* 43, 257). Solidifies a little above  $0^\circ$ .—BaA<sub>2</sub>.—EtA<sub>2</sub>.

**n-DO-ICOSANE**  $C_{22}H_{44}$ . [45°]. (225°) at 15 mm. S.G.  $d_4^{20}$  .755;  $d_4^{25}$  .742. Formed by reduction of the dichloride of the ketone obtained by distilling a mixture of barium palmitate and heptoate (Krafft, *B.* 15, 1718; 21, 2256). Present also in paraffin derived from bituminous shale by distillation.

**DOTRIACONTANE** *c.* **DICETYL**.

**DOUBLE SALTS.** By a salt was meant in the early days of chemistry a solid substance *e. sol.* water and re-obtainable by evaporating its aqueous solution. When the composition and modes of formation of bodies with these properties came to be examined, it was found that many of them were formed by the interaction of an acid with an alkali, and were composed of the elements of the acid and the alkali. Hence the study of salts carried with it the study of acids and alkalis. Acids and alkalis were at first described as compounds with certain characteristic properties, rather physical than chemical (*v.* **ACIDS** and **ALKALIS**); the more accurate study of these bodies showed that all acids are composed of hydrogen combined with a strongly negative element or elements, and that all alkalis are compounds of markedly positive metals with hydrogen and oxygen. By

**Composition of salt when regarded as**

Salt.	(1) derivative of an acid.	(2) compound of two radicles.
KNO <sub>3</sub>	K.NO <sub>3</sub> (acid = HNO <sub>3</sub> )	K.O.N.O <sub>3</sub> (= 2KNO <sub>3</sub> )
K <sub>2</sub> SO <sub>4</sub>	K <sub>2</sub> .SO <sub>4</sub> (acid = H <sub>2</sub> SO <sub>4</sub> )	K <sub>2</sub> O.SO <sub>4</sub>
KHSO <sub>4</sub>	K.HSO <sub>4</sub> (acid = H <sub>2</sub> SO <sub>4</sub> )	K <sub>2</sub> O.2SO <sub>4</sub> .H <sub>2</sub> O (= 2KHSO <sub>4</sub> )
AlPO <sub>4</sub>	Al.PO <sub>4</sub> (acid = H <sub>3</sub> PO <sub>4</sub> )	Al <sub>2</sub> O <sub>3</sub> .P <sub>2</sub> O <sub>5</sub> (= 2AlPO <sub>4</sub> )

There are many salts which cannot well be formulated as derived from acids by replacing hydrogen by a metal, but rather as compounds of such salts with the oxide, or hydroxide, of the replacing metal: As instances of these *basic salts* may be mentioned Bi(NO<sub>3</sub>)<sub>3</sub>.Bi<sub>2</sub>O<sub>3</sub> and PbC<sub>2</sub>H<sub>3</sub>O<sub>7</sub>.Pb(OH)<sub>2</sub>. Such salts may, however, be formulated as compounds of two radicles, one negative and the other positive; thus  $3Bi_2O_3.3N_2O_5 = 2[Bi(NO_3)_3.Bi_2O_3]$ ,  $2PbO.C_2H_3O_7.H_2O = PbC_2H_3O_7.Pb(OH)_2$ .

Some salts are composed of two metals combined with an acidic radicle or radicles; so far as composition is concerned these *double salts* may be regarded either as derived from an acid or from two acids, by exchanging hydrogen for two metals, or as composed of two positive radicles combined with a negative, or with two negative, radicles. They may also be formulated as compounds of two salts. The following examples will illustrate these conceptions of *double salts* :—

**Composition of salt when regarded as**

Double salt.	I. Derivative of acid or acids.	II. Composed of radicles.	III. Composed of two salts.
Al <sub>2</sub> K <sub>2</sub> SO <sub>4</sub>	Al <sub>2</sub> K <sub>2</sub> .4SO <sub>4</sub> (acid = H <sub>2</sub> SO <sub>4</sub> )	Al <sub>2</sub> O <sub>3</sub> .K <sub>2</sub> O.4SO <sub>4</sub>	Al <sub>2</sub> (SO <sub>4</sub> ) <sub>3</sub> .K <sub>2</sub> SO <sub>4</sub> .
MgNa <sub>2</sub> C <sub>2</sub> O <sub>4</sub>	MgNa <sub>2</sub> .2CO <sub>3</sub> (acid = H <sub>2</sub> CO <sub>3</sub> )	MgO.Na <sub>2</sub> O.2CO <sub>3</sub>	MgCO <sub>3</sub> .Na <sub>2</sub> CO <sub>3</sub> .
Cd(NH <sub>4</sub> ) <sub>2</sub> Cl <sub>2</sub>	Cd(NH <sub>4</sub> ) <sub>2</sub> .6Cl (acid = HCl)	Cd.4NH <sub>3</sub> .6Cl	CdCl <sub>2</sub> .4NH <sub>4</sub> Cl.
Hg <sub>2</sub> CaCy <sub>2</sub> Cl <sub>2</sub>	Hg <sub>2</sub> Ca.Cy <sub>2</sub> Cl <sub>2</sub> (acids = HCY and HCl)	Hg <sub>2</sub> .Ca.Cl <sub>2</sub> Cy <sub>2</sub>	HgCy <sub>2</sub> .CaCl <sub>2</sub> .
HgAgCy <sub>2</sub> NO <sub>3</sub>	HgAg.Cy <sub>2</sub> NO <sub>3</sub> (acids = HCY and HNO <sub>3</sub> )	Hg.Ag.Cy <sub>2</sub> NO <sub>3</sub>	HgCy <sub>2</sub> .AgNO <sub>3</sub> .

To this class of *double salts* also belong compounds composed of a single metal combined with two acidic or negative radicles, thus :—

Hg <sub>2</sub> I <sub>2</sub> SO <sub>4</sub>	Hg <sub>2</sub> I <sub>2</sub> SO <sub>4</sub> (acids = H <sub>2</sub> SO <sub>4</sub> and HI)	Hg <sub>2</sub> I <sub>2</sub> SO <sub>4</sub>	HgI <sub>2</sub> .HgSO <sub>4</sub> .
--	--	--	---------------------------------------

the interaction of an acid and an alkali a salt is formed; the salt is not characterised by the properties either of the acid or the alkali; the salt is composed of the metal of the alkali combined with the more negative part of the acid. Then it was found that salts could be formed in other ways than by the interaction of acid and alkali; but, however formed, the salt is a compound of a positive element (a metal) with a negative element or group of elements.

A salt may, then, be described either as a derivative of an acid obtained by exchanging the whole or a portion of the hydrogen of the acid for metal, or as a compound of two radicles, one positive and the other negative. If the latter form of description is adopted, the positive radicle of the salt may generally be regarded either as a metal or as a group composed of a metal and non-metal, the non-metal being usually oxygen, and the negative radicle may be regarded as either a non-metal or a group composed of negative elements. The following formulae represent the composition of some salts :—

The most generally applicable way of looking at double salts, when attention is paid solely to composition, is evidently to regard them as composed of two salts. All double salts will thus be brought within the general formula  $xM.yN$ , where M is one salt and N another. But if the constitution of the double salts is to be understood, and the salts are to be classified, attention must be paid not only to their composition but also to their properties. Some double salts interact with various reagents as chemical wholes; thus the body FeCy<sub>2</sub>.4KCy reacts with acids to give the acid H<sub>2</sub>FeCy<sub>4</sub> and a salt of K; so also it reacts with many metallic salts in solution to give pps. of the composition M<sup>1</sup>FeCy<sub>2</sub> or M<sup>11</sup>FeCy<sub>2</sub>, where M<sup>1</sup> is a monovalent, and M<sup>11</sup> a divalent, metal. The double salt in question is therefore regarded as the K salt of the acid H<sub>2</sub>FeCy<sub>4</sub>, and its formula is written K<sub>2</sub>FeCy<sub>4</sub>, a formula which is strictly conformable with FeCl<sub>2</sub>, Fe(NO<sub>3</sub>)<sub>2</sub>, Fe<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>, and other formulæ of simple salts. Other double salts interact with various reagents as if they were composed of two

simple salts; thus,  $\text{AgCy.KCy}$  reacts with acids to produce  $\text{HCy}$ , a salt of  $\text{Ag}$ , and a salt of  $\text{K}$ . Other double salts react with some reagents in one way, and with others in another way; for instance,  $\text{HgCy}_2.2\text{KC}_y$  is decomposed by acids with evolution of  $\text{HCy}$ , but an aqueous solution of this double salt reacts with lead or zinc salts to form a pp. of  $\text{HgCy}_2.\text{PbCy}_2$ , or  $\text{HgCy}_2.\text{ZnCy}_2$ , respectively. In the latter changes the double salt  $\text{HgCy}_2.2\text{KC}_y$  reacts as if it were  $\text{K}_2\text{HgCy}_4$ .

A slight extension of the application of the conception of compound radicles is probably sufficient to bring the double salts within the generally accepted notions of chemical constitution. If we examine a few reactions of a specified compound, we may arrive at a conception of its constitution which finds expression in a structural formula representing the compound as built up of certain radicles. But a more exhaustive study of the same compound may lead to another structural formula. Thus, the formulæ  $\text{H.C}_2\text{H}_3\text{O}_2$ ,  $\text{C}_2\text{H}_3\text{O.OH}$ , and  $\text{CH}_3.\text{COOH}$  mark successive advances in the chemical study of acetic acid. The third formula is the best, because it suggests more reactions than either of the others. In the case of such a compound as acetic acid we cannot actually build up the compound from the radicles which we represent in the formula. But we are generally able to build up a double salt by bringing together two simple salts; hence we are apt to think that the atomic complex which forms the reacting unit of the salt must be composed of these two radicles which have actually been caused to combine. This may not, however, be the proper view to take of the constitution of the salt; whether it is or is not the proper view can be determined only when an exhaustive study has been made of the reactions of formation and decomposition of the compound. But as most double salts have only been superficially examined, our present conceptions of the constitution of these bodies cannot be regarded as final. In connexion with the subject of double salts v. article SALTS. M. M. P. M.

**DRAGON'S BLOOD.** A red resin. American dragon's blood flows from incisions in *Pterocarpus draco* growing in the West Indies. A similar resin is obtained from *Croton draco*. Indian dragon's blood is found on the ripe fruits and leaves of various species of *Calamus*. Canary dragon's blood comes from *Dracana draco*. It dissolves in alcohol, ether, and oils, forming a red solution. It is partially soluble in alkalis (Johnstone, *Tr.* 1839, 134; Herberger, *Buchn. Rept.* 37, 17; 40, 138). According to Dobbie a. Henderson (*Ph.* [3] 14, 361) these resins may be arranged in four groups:—

- (a) Sol.  $\text{CHCl}_3$ ,  $\text{CS}_2$ , and benzene.
- (b) Sol.  $\text{CHCl}_3$ , insol.  $\text{CS}_2$ , and benzene.
- (c) Sol.  $\text{CHCl}_3$ , partly sol.  $\text{CS}_2$ , sol. benzene.
- (d) Insol.  $\text{CHCl}_3$ ,  $\text{CS}_2$ , and benzene.

The other properties of these resins are somewhat dissimilar:—

- (a)  $\text{C}_{10}\text{H}_{16}\text{O}_4$ . [80°]. From *Calamus draco*.
- (b)  $\text{C}_{10}\text{H}_{16}\text{O}_4$ . [c. 100°].
- (c)  $\text{C}_{10}\text{H}_{16}\text{O}_4$ . [c. 80°]. From *dracæna*.

The following properties probably relate chiefly to the resin from *Pterocarpus draco*:—

On dry distillation it gives toluene and styrene (Glénard a. Boudault, *C. R.* 17, 503; 19, 505; Blyth a. Hofmann, *A.* 53, 326). Potash-fusion

forms benzoic acid, *p*-oxy-benzoic acid, and phloroglucin (Hlasiwetz a. Barth, *A.* 134, 283). Distillation with zinc-dust gives a large quantity of styrene, together with toluene, ethyl-benzene, and three oils,  $\text{C}_{11}\text{H}_{18}\text{O}$  (215°) V.D. 5.6,  $\text{C}_{11}\text{H}_{18}\text{O}$  (258°) V.D. 6.96, and  $\text{C}_{12}\text{H}_{20}\text{O}$ , (238°) (Bötsch, *M.* 1, 609).

#### DRUPOSE v. SUGAR.

**DUALISM.** As the study of chemical composition was developed by Lavoisier, Dalton, Davy, Berzelius, and others, chemists gradually drew a marked line of distinction between two classes of compounds, those namely which when dissolved in water had a sour taste, dissolved metals, corroded animal matter, and changed the colour of some vegetable substances from blue to red, and those whose aqueous solution had a soap-like action on the skin, did not dissolve metals, and restored the colour of the vegetable substances which were altered by the first class of compounds. But these two groups of compounds comprised a minority of the bodies which it was the business of chemistry to investigate. There were very many substances which did not possess the characteristics of either class; as investigation proceeded it was discovered that the greater number of the members of the intermediate class could be produced by the interaction of bodies belonging to one of the extreme classes with bodies belonging to the other. Compounds belonging to the first class were called acids, the second class was named bases or alkalis, and a compound formed by the mutual action of an acid and a base was called a salt.

The mode of production of salts suggested the view that these compounds are built up of two parts, one of which has the characters of an acid, and the other the characters of a base. This view was confirmed by the results of the electro-chemical researches of Davy and Berzelius. The passage of an electric current through a salt very frequently produced one body having the characters of an acid, and another having the properties of a base. Berzelius supposed that every salt is essentially composed of two parts, one of which is electrically positive to the other; in some cases each part or radicle of a salt is itself an element, in other cases each part is itself a group of elements.

Having expounded his view of chemical action as an electrical phenomenon essentially consisting in the attraction of one body, either elementary or compound, by another with an electrical polarity stronger than that of the first, Berzelius proceeds thus:—

'If these electro-chemical conceptions are just, it follows that every chemical compound is dependent on two opposing forces, positive and negative electricity, and on these alone; and that every compound must be composed of two parts held together by their mutual electro-chemical reactions. Therefore it follows that every compound body, whatever be the number of its constituents, can be separated into two parts, whereof one is positively and the other negatively electrified. Thus, for example, sodium sulphate is put together, not from sulphur, oxygen, and sodium, but from sulphuric acid and soda, which again can themselves be separated into positive and negative constituents. So also alum cannot be regarded as immediately built up from its elements, but must rather be looked on as the product of a reaction between sulphate of alumina and sulphate of potash, the former acting as a negative, the latter as a positive element.'—*ibid.*, 3, pt. 1. 77.

This is the doctrine of *dualism*, a doctrine which prevailed in chemistry for something like half a century. As soon as a new salt was prepared, the dualistic chemist set himself to construct a formula which should represent the salt as composed of two parts, or radicles, one positive and the other negative. The formula given to the same salt was not always the same; but in whatever way the formula was modified, in accordance with the known reactions of the salt, the fundamental conception of binary structure remained. The following formulæ, among others, were given at different times to sodium acetate—(C = 6, O = 8):—

The conception on which dualism was based, the conception, namely, of binary structure, was extended to acids and bases; every acid and every base was regarded as composed of two radicles, one of which was frequently, but not always, an element. A complete system of chemical classification was thus developed: one element combines with another; the compound is evidently a binary one; the compound interacts with another binary compound; the product is still binary although each part is itself a compound; the new compound enters into chemical union with a compound as complex as itself; the product is still essentially built up of two parts. Each elementary atom was regarded by Berzelius as endowed with both positive and negative electricity, but one of these predominated over the other, so that the atom, considered as a whole, was either negatively or positively electrified. When a positively electrified atom combined with one which was negatively electrified, Berzelius said that opposite electricities neutralised each other, but, he added, the electricities formerly masked in the separate atoms now come into play, so that the new group of atoms, considered as a whole, is either positively or negatively electrified, and in virtue of this the new group of atoms is ready to combine with other atoms or groups of atoms, provided the predominating electricity on these is of opposite sign to that on the first group. As compounds become more complex the less readiness do they exhibit to enter into fresh combinations; this was accounted for by Berzelius as a consequence of the neutralisation of the predominating or stronger electricities by the first combination of the elementary atoms. Suppose an atom to have a large charge of positive and a small charge of negative electricity, and suppose this atom to come within the sphere of action of another having a large charge of negative and a small charge of positive electricity; these atoms will have a great affinity for each other—according to the Berzelian doctrine of dualism—they will combine, and the compound will be either positively or negatively electrified, but the total charge will be considerably smaller than that on the original atoms.

Chemical affinity was regarded by the Berzelian school as conditioned by, if not as synonymous with, greater or smaller electrical charges. Suppose that a series of binary compounds has

been produced, one of these being very stable, another less stable, another unstable, and so on, the electrical charges on the atoms of the most stable compound must have been greater than the charges on the atoms of the less stable compounds; therefore a greater quantity of electricity will be required to tear asunder the atoms which form the most stable compound than is required to decompose an equivalent quantity of one of the less stable compounds. But Faraday's researches on electrolysis showed that the passage of the same quantity of electricity through a series of electrolytic compounds of varying chemical stability resulted in the decomposition of chemically equivalent masses of these compounds. This result was opposed to the dualistic conception of affinity, and hence to the whole system of dualism.

The researches of Liebig and Graham on the constitution of acids gradually led chemists to regard these bodies as essentially compounds of hydrogen with negative elements or groups of elements; they came to look on the reaction between an acid and a metal as consisting in the replacement of part, or the whole, of the hydrogen of the acid by the metal, and they recognised that the hydrogen of some acids could be replaced by metal in two, three, or more, successive stages. An acid thus came to be regarded as a whole, the functions of the parts of which depend on the nature of these parts, and probably on their arrangement relatively to each other. But the dualistic chemist asserted that hydrogen belongs to the class of metals, because both are distinctly positive elements, and he maintained that the replacement of one positively electrified atom by another positively electrified atom might be expected to result in the production of a compound resembling the original; the acid type is preserved, he asserted, when a salt is formed by putting a metal in the place of the hydrogen of an acid; both acid and salt are dualistic structures of the same kind. It is impossible, asserted the follower of Berzelius, to replace the strongly positive hydrogen in a compound by a distinctly negative element without producing a compound of an entirely different type from the acid; a negative element, such as chlorine, cannot, he said, be put in the place of the positive element hydrogen; if hydrogen is removed and a compound containing chlorine is formed, this process must consist in the breaking down of one dualistic structure and the formation of another totally unlike the first. But in 1839 Dumas prepared trichloroacetic acid and proved this compound to be very similar to acetic acid, although it was produced by replacing three atoms of hydrogen in acetic acid by three atoms of the markedly negative element chlorine (C. R. 8, 609). Dumas retained the notion of types or families; but he said that compounds were to be placed in this or that family, because of their actual reactions of formation and decomposition, and not because a certain hypothesis required them to be classified in a certain way.

Dualism had paid too exclusive attention to composition; Dumas, and the founders of the *unitary hypothesis*, maintained that no chemical classification can be approximately final which does not endeavour to study the properties as well as the compositions of the bodies to be

classified (v. CLASSIFICATION; also SALTS, and TYPES). M. M. P. M.

**DUBOISINE.** Identical with HYOSCYAMINE (q. v.).

**DULCAMARIN**  $C_{22}H_{21}O_9$ . Occurs in the stalks of the common nightshade, *Solanum dulcamara* (Wittstein, *Vierteljahrh. f. pr. Pharm.* 1, 864, 495; E. Geissler, *Ar. Ph.* [3] 7, 289). Amorphous, with bitter taste followed by a persistent sweet taste. Sol. alcohol. and acetic ether. Basic lead acetate ppts.  $C_{22}H_{21}PbO_9$ , 3aq and  $C_{22}H_{21}PbO_9$ , 5aq. Dilute acids resolve it into glucose and resinous dulcamaretin  $C_{16}H_{15}O_6$ .

**DULCITE**  $C_8H_{12}O_4$ , i. e.  $CH_2(OH)(CH.OH).CH_2OH$ . *Melampyrite*. Mol. w. 182. [189°]. S.G. 1.466. S. 3 at 15°. S. (alcohol) .07 at 15°. H.F. 294,000 (v. Rechenberg); 317,600 (Berthelot a. Vieille, *A. Ch.* [6] 10, 456; *Bl.* [2] 47, 868). H.C.v. 729,100; H.C.p. 729,400 (B. a. V.).

**Occurrence.**—In Madagascar manna (Laurent, *Compt. Chim.* 1850, 364; 1851, 29; *A.* 76, 358; 80, 345; Jacquelin, *Compt. Chim.* 1851, 21; *A.* 80, 345). In *Melampyrum nemorosum* (Hünefeld, *J. pr.* 7, 233; 9, 47; *A.* 24, 241; Gilmer, *A.* 123, 372); in *Scrophularia nodosa* and *Rhinanthus Crista-galli* (Eichler, *Rep. Chim. pure*, 2, 103); and in the cambial cells of *Euonymus europaeus* (Kubel, *J. pr.* 85, 372).

**Formation.**—By reducing galactose or milk sugar with sodium amalgam (Bouchardat, *A. Ch.* [4] 27, 68; *C. R.* 83, 199; 84, 665, 866, 1406; *Bl.* [2] 18, 115).

**Preparation.**—1. From Madagascar manna by recrystallisation. —2. The decoction from *Melampyrum nemorosum* is boiled with addition of milk of lime, and the solution concentrated; the hot solution is acidified with HCl, and on cooling dulcitol crystallises out (Eichler).

**Properties.**—Glittering monoclinic prisms, usually aggregated in crusts. Slightly sweet in taste. Inactive. Sl. sol. acetone, chloroform, and acetic ether, insol. ether. It does not reduce Fehling's solution. Does not undergo alcoholic fermentation. At 200° it loses water, becoming dulcitan  $C_8H_{12}O_3$ , a thick syrup. Dulcitol is neutral to litmus, but according to Klein (*C. R.* 99, 144) a solution of dulcitol (1 mol.) mixed with borax ( $\frac{1}{2}$  mol.) is acid. Sodium paratungstate acts like borax.

**Reactions.**—1. Boiling dilute nitric acid forms mucic, racemic, and oxalic acids (Laurent; Carlet, *C. R.* 51, 137; 53, 343). Fuming  $HNO_3$  forms the hexanitrate. —2.  $H_2SO_4$  forms a penta-sulphuric acid. —3. HI forms secondary hexyl iodide (Erlenmeyer a. Wanklyn, *C. J.* 15, 455). —4. Conc. HClAq at 0° forms unstable crystals of  $C_8H_{12}O_4.HCl$  3aq (Bouchardat, *A. Ch.* [4] 27, 168). —5. HClAq at 100° slowly forms the dichlorhydrin  $C_8H_{12}Cl_2O_4$ . This forms tables, insol. water and alcohol; it is split up at 180°, or by boiling water, into HCl and dulcitolan chlorhydrin  $C_8H_{11}ClO_4$ , which crystallises from ether in needles [90°], and is partially converted by boiling water into dulcitan. The dichlorhydrin is converted by alcoholic  $NH_3$  into dulcitamine  $C_8H_{11}NO_4$ , a strongly alkaline syrup which absorbs  $CO_2$  from the air and forms a crystalline hydrochloride  $B.HCl$  and platinohloride  $B'.H_2PtCl_6$ . Sodium amalgam converts dulcitolan dichlorhydrin into gummy dulcitolan  $C_8H_{12}O_4$ .

Vol. II.

Fuming  $HNO_3$  gives  $C_8H_{11}Cl(NO_3)$ , [108°]. 6. HBr gives  $C_8H_{11}O_4.HBr$  3aq,  $C_8H_{11}BrO_4$ , and  $C_8H_{11}BrO_4$ , [143°] under conditions similar to those under which the corresponding chlorine derivatives are formed. The prolonged action of a large excess of HBrAq at 100° forms syrup  $C_8H_{11}BrO_4$ . Dulcitolan chlorhydrin is converted by HBrAq at 100° into crystalline  $C_8H_{11}ClBrO_4$ . Dulcitolan dibromhydrin is converted by fuming  $HNO_3$  into  $C_8H_9Br_2(NO_3)$ , [100°]; while  $C_8H_{11}ClBrO_4$  gives  $C_8H_9ClBr(NO_3)$ , [115°]. —7. HIAq (S.G. 2.0) at 15° forms  $C_8H_{11}O_4.HI$  3aq, which is completely resolved into its components by water. —8. Boiling  $AcCl$  forms  $C_8H_{11}Cl(OAc)$ , which forms minute crystals. —9.  $Ac_2O$  forms several acetyl derivatives (v. *infra*). Butyric acid at 200° gives oily di-butyryl dulcitolan  $C_8H_{10}(C_4H_7O_2)_2$ . —10. If bromine (5 g.) be added to a solution of dulcitol (5 g.) in water (40 g.) containing  $Na_2CO_3$  (12 g.), and the product subsequently tested with phenyl hydrazine, the phenyl hydrazone  $C_8H_{12}N_2O_4$  [206°] of an aldehyde or ketone ('phenyl dulcitosazone') separates as yellow flakes (Fischer a. Tafel, *B.* 20, 3384). —11. By heating dulcitol with phenyl cyanate there is formed  $C_8H_9(OH)(O.CO.NHPh)$ , [c. 252°], very sparingly soluble in all solvents (Tessmer, *B.* 18, 971).

**Metallic compounds.**— $C_8H_{12}BaO_4$  8aq; prisms, v. sol. warm water. — $C_8H_{12}PbO_4$  8aq (at 100°). — $C_8H_{12}Cu_2O_4$  8aq (at 100°).

**Hexanitrate**  $C_8H_9(NO_3)_6$ . *Nitrodulcitol*. [c. 70°]. From dulcitol (1 pt.), fuming  $HNO_3$  (5 pts.), and  $H_2SO_4$  (10 pts.), the mixture being immediately thrown into water (Béchamp, *C. R.* 51, 257; Champion, *Bl.* [2] 22, 179). Colourless flexible needles (from alcohol). When kept for a month at 30° to 45° it evolves red fumes, and apparently changes to the tetranitrate  $C_8H_9(OH)_2(NO_3)_4$ , [130°–140°], which crystallises from alcohol in prisms.

**Tri-sulphuric acid**  $C_8H_9(SO_3H)_3(OH)$ . From dulcitol and  $H_2SO_4$  (Eichler). — $Ba_3A''$ : gummy.

**Penta-sulphuric acid**  $C_8H_9(SO_3H)_5(OH)$ . When dulcitol is added in small portions to chlorosulphuric acid ( $ClSO_3H$ ), and the product is dissolved in water, a solution is obtained whence a barium salt may be got in the form of a hygroscopic powder. Writing bar for  $\frac{1}{2}Ba$ , it is either  $(BaSO_3)_2C_8H_9(OH)_2$  2aq or  $(BaSO_3)_3C_8H_9$  3aq. The latter formula represents it as derived from dulcitolan, and, in fact, if the free acid is heated on the water-bath dulcitolan is produced (Claesson, *J. pr.* 128, 15).

**Di-acetyl derivative**  $C_8H_9(OH)_2(OAc)_2$ , [176°]. From boiling  $Ac_2O$  (12 pts.),  $HOAc$  (120 pts.), and dulcitol (10 pts.) (Bouchardat). Scales. Sl. sol. cold water, insol. ether. A by-product is diacetyl dulcitolan  $C_8H_9Ac_2O_3$ , a bitter substance, sol. water and ether.

**Penta-acetyl derivative**  $C_8H_9(OH)(OAc)_5$ , [163° cor.]. From  $C_8H_9Cl(OAc)$ , by boiling with alcohol. Needles.

**Hexa-acetyl derivative**  $C_8H_9(OAc)_6$ , [171° cor.]. From dulcitol (1 pt.),  $Ac_2O$  (5 pts.), and  $HOAc$  at 185°. Hard crystalline plates; sublimes at 210°. A by-product in its preparation is tetra-acetyl-dulcitolan  $C_8H_9O(OAc)_4$ , an insupportably bitter resin.

E E

**Hexa-benzoyl derivative**  $C_6H_5(Obz)_6$  [147]. From dulcitol (1 mol.) and  $BzCl$  (8 mols.) at  $150^{\circ}$ - $200^{\circ}$ . Crystals (from alcohol), insol. water and ether.  $HNO_3$  mixed with  $H_2SO_4$  convert it into  $C_6H_5(O.CO.C_6H_5)_6$ . Tetra-benzoyl-dulcitolan  $C_6H_5O(Obz)_4$  is a resin formed as a by-product in preparing hexa-acetyl-dulcitol.

Isodulcitol  $C_6H_{11}O_6$  or  $C_6H_{12}O_6$  aq. *Rhamnose*. [92°]. S.G.  $d_4^{20}$  1.471. S.  $56.7$  at  $18^{\circ}$ ;  $109$  at  $40^{\circ}$ .  $[\alpha]_D^{20} = -8.07^{\circ}$  in a 21 p.c. aqueous solution at  $17^{\circ}$ ;  $[\alpha]_D^{20} = -13^{\circ}$  in fresh solutions (Rayman a. Kruis, *C. O.* 1888, 6). Prepared by the action of dilute  $H_2SO_4$  upon quercitrin (the yield being 10 p.c., Hlasiwetz a. Pfaundler, *A.* 127, 362), upon the glucoside of buckthorn berries (*Rhamnus infectoria*) Liebermann a. Hörmann, *B.* 11, 952; Berend, *B.* 11, 1353), and upon sophorin (Förster, *B.* 15, 215). Monoclinic crystals, sol. water and alcohol. In very dilute alcoholic solutions it is levorotatory, in concentrated alcoholic and in aqueous solution it is dextrorotatory. 10 c.c. of Fehling's solution, equivalent to .05 g. glucose, are reduced by .055 g. isodulcitol (Will, *B.* 18, 1316). Isodulcitol also reduces ammoniacal silver nitrate, Knapp's reagent, an alkaline solution of indigo, an alkaline solution of  $K_2FeC_6$ , and picric acid (to picramic acid). It does not affect Schiff's reagent.  $H_2SO_4$  dissolves it unchanged. Does not undergo alcoholic fermentation with yeast. At  $100^{\circ}$  it gives off  $H_2O$  becoming  $C_6H_{12}O_6$ , sometimes called isodulcitolan, which takes up  $H_2O$  again on dissolving in water.

**Reactions.**—1. *Polash and iodine* give a very little iodoform.—2. (a) *Naphthol* and  $H_2SO_4$  give a bluish-violet colour.—3. *Thymol* and  $H_2SO_4$  give a crimson zone rapidly turning brown.—4. *Phenyl hydrazine* mixture gives a heavy pp.  $C_6H_5O_2(N_2HPh)_2$  or  $C_6H_{12}N_2O$ , [171°] sl. sol. water, v. sol. alcohol (Rayman, *Bl.* [2] 47, 668; Herzog, *M.* 8, 227).—4. Heated with phenyl-hydrazine in alcoholic solution it gives a phenyl-hydrazide  $C_6H_5N_2O$  or  $C_6H_{12}O(N_2HPh)$  [159°] v. sl. sol. alcohol (Rayman, *Bl.* [2] 47, 760; Fischer a. Tafel, *B.* 20, 2566).—5. A mixture of  $H_2SO_4$  and  $HNO_3$  forms a very unstable explosive nitrate  $C_6H_5(NO_3)_6$ .—6. *Moist silver oxide* oxidises isodulcitol to acetic acid.  $CrO_3$  does the same. *Bromine* followed by  $Ag_2CO_3$  oxidises it to  $C_6H_5O_2$ , [148°] (Will a. Peters, *B.* 21, 1813), or [142°] (Rayman, *B.* 21, 2046). This 'isodulcitol saccharin' forms needles, v. sol. water and alcohol, sl. sol. ether;  $[\alpha]_D^{20} = -39^{\circ}$ ; S.G.  $d_4^{20}$  1.0325; S. 11.—7. Aqueous  $NaOH$  and  $BzCl$  form a crystalline mixture of tri- and tetra-benzoyl derivatives.—8.  $Ac_2O$  at  $120^{\circ}$ - $140^{\circ}$  forms resinous acetyl derivatives.

**Sodium salt**  $C_6H_5Na_2O_6$ . From isodulcitol and alcoholic  $NaOEt$  (Liebermann a. Hamburger, *B.* 12, 1186). Crystalline powder.

**Isodulcitol carboxylic acid**  $C_6H_5O_7$ . *Lactone*  $C_6H_5O_6$ , [168°]. Formed by heating isodulcitol (25 g.) dissolved in water (25 c.c.) with anhydrous  $HCl$  (7.5 c.c.) at  $80^{\circ}$ ; and subsequent saponification (Fischer a. Tafel, *B.* 21, 1657; 2173). Concentrically grouped needles, v. sol. water and alcohol, v. sl. sol. ether. Reduced by  $HI$  and  $P$  to  $n$ -heptonic acid.

**ISODULCITIC ACID**  $C_6H_5O_7$ , [100°]. Formed by oxidising isodulcitol with  $HNO_3$  (S.G. 1.33) (Malin, *A.* 145, 197). Crystalline grains, v. sol.

water, v. sl. sol. alcohol. Does not reduce Fehling's solution.— $C_6H_5Pb_2O_6$ — $C_6H_5CaO_6$  (at  $120^{\circ}$ ).— $C_6H_5BaO_6$  (at  $120^{\circ}$ ): white pp.— $C_6H_5CaO_6$  (at  $120^{\circ}$ ).

#### ISO-DULCITONIC ACID $C_6H_5O_7$ .

**Formation.**—By oxidising isodulcitol with bromine the lactone of isodulcitolonic acid is formed. This is converted into salts of the acid by boiling with the respective carbonates (Will a. Peters, *B.* 21, 1814).

**Properties.**—The free acid is not known. When liberated from the salts it is always the lactone [148°] which is ppd.

**DUMASIN**  $C_6H_5O$  (Kane);  $C_6H_5O$  (Heintz, *P.* 68, 279; Fittig, *A.* 110, 21). V.D. 5.2 (Kane). One of the products obtained by passing acetone or acetic acid through red-hot tubes (Kane, *P.* 44, 494) or by the rapid distillation of acetates. Oil. Lighter than water. Resembles mesityl oxide. Combines with  $NaHSO_4$ , the crystalline compound  $C_6H_5ONaHSO_4$  2aq being decomposed by boiling water. On distillation with  $MnO_2$  and  $HCl$  it gives  $C_6H_5Cl_2O$  ( $150^{\circ}$ - $155^{\circ}$ ).

#### DUODECANE v. DODECANE.

**DURENE**  $C_{10}H_8$ , i.e.  $C_6H_4(CH_3)_2$ , [1:2:4:5]. *s*-Tetra-methyl-benzene. Mol. w. 134. [81°] ( $196^{\circ}$  i. V.).

**Occurrence.**—In the fraction  $170^{\circ}$ - $180^{\circ}$  of coal-tar oils (Schulze, *B.* 18, 3032; cf. Berthelot, *Bl.* [2] 8, 226).

**Formation.**—1. From bromo- $\psi$ -cumene [71°],  $MeI$ , and  $Na$  (Jannasch a. Fittig, *Z.* 1870, 161; Nef, *A.* 237, 3; Gattermann, *A.* 214, 56).—2. From di-bromo-*m*-xylene  $MeI$ , and  $Na$  (Jannasch, *B.* 7, 692; Gissmann, *A.* 216, 201). Similarly from di-bromo-*p*-xylene (Jannasch, *B.* 10, 1357).—3. By the action of  $MeCl$  in presence of  $AlCl_3$  upon toluene, *o*- or *p*-xylene, or  $\psi$ -cumene (Friedel a. Crafts, *A. Ch.* [6] 1, 461; 11, 270; Ador a. Rilliet, *B.* 12, 331; Jacobsen, *B.* 14, 2629).—4. By the action of  $MeI$  on a mixture of  $\psi$ -cumene,  $CS_2$ , and  $AlCl_3$  at  $100^{\circ}$  (Claus a. Föcking, *B.* 20, 3097).—5. In small quantity by passing oil of turpentine through a red-hot tube (Montgolfier, *A. Ch.* [5] 19, 164).

**Properties.**—Monoclinic crystals with faint odour. V. sol. alcohol, ether, and benzene, sl. sol. cold  $HOAc$ . May be sublimed.

**Reactions.**—1. Gives by oxidation pyromellitic acid  $C_6H_4(CO_2H)_4$ , tri-methyl-benzoic acid  $C_6H_3(CH_3)_3(CO_2H)$ , di-methyl-benzoic acid  $C_6H_4(CH_3)_2(CO_2H)$ , and acetic acid (Reuter, *B.* 11, 31).—2. By leaving in contact with 10 times its weight of ordinary conc.  $H_2SO_4$ , about  $\frac{1}{4}$  of it is converted into a *mono-sulphonic acid*. This sulphonic acid is very unstable, being partially reconverted into durene by cold conc.  $H_2SO_4$ . By the prolonged (3 or 4 days') action of conc.  $H_2SO_4$  in the cold or for a shorter time at  $80^{\circ}$ - $100^{\circ}$  upon durene or its sulphonic acid a complicated reaction takes place with production of two pseudo-cumene-sulphonic acids  $C_6H_4Me_2(SO_3H)$  [1:3:4:5] and [1:3:4:2], a sulphonic acid of the (1:2:3:4) tetra-methyl-benzene (prehnitene), and hexa-methyl-benzene. In this remarkable reaction the  $H_2SO_4$  behaves in a similar manner to  $AlCl_3$ . By the action of cold fuming  $H_2SO_4$  upon durene a disulphonic acid is obtained which is much more stable than the mono-sulphonic acid (Jacobsen, *B.* 19, 1209).—

8. Heated with  $\text{PCl}_5$  at  $195^\circ$  it gives a chloride  $\text{C}_{10}\text{H}_7\text{Cl}$ , which when treated with water at  $175^\circ$  loses all its chlorine. As there is no acid formed it is probable that this chloride contains neither the group  $\text{CCl}_2$  nor the group  $\text{CHCl}_2$ . A chloride  $\text{C}_{10}\text{H}_7\text{Cl}_2$  may be obtained from the ligroin which serves to purify the  $\text{C}_{10}\text{H}_7\text{Cl}$ ; it is changed by boiling water into a viscous mass, sl. sol. ether (Colson a. Gautier, *A. Ch.* [6] 11, 30).—4. *Benzoyl chloride* in presence of  $\text{Al}_2\text{Cl}_6$  at  $120^\circ$  forms phenyl tetra-methyl-phenyl ketone  $\text{C}_6\text{H}_5\text{CO}_2\text{C}_6\text{HMe}$ , [ $119^\circ$ ] ( $343^\circ$ ), and di-phenyl tetra-methyl-phenylene diketone  $(\text{C}_6\text{H}_5\text{CO})_2\text{C}_6\text{Me}$ , [ $270^\circ$ ] (Friedel, Crafts, a. Ador, *C.R.* 88, 880).—5. *Acetyl chloride* and  $\text{Al}_2\text{Cl}_6$  give  $\text{C}_6\text{HMe}_2\text{CO}_2\text{CH}_3$  ( $253^\circ$  uncor.) which may be oxidised to  $\text{C}_6\text{HMe}_2\text{CO}_2\text{CO}_2\text{H}$  whence sodium-amalgam produces  $\text{C}_6\text{HMe}_2\text{CH}(\text{OH})\text{CO}_2\text{H}$  [ $156^\circ$ ] (Claus a. Facking, *B.* 20, 3097).

*u-Durene*  $\text{C}_6\text{H}_4(\text{CH}_3)_2$ , [1:3:4:5]. *Isodurene*, ( $196^\circ$  i. V.).

*Formation*.—1. From bromo-mesitylene,  $\text{MeI}$ , and sodium (Jannasch, *B.* 8, 356).—2. By the action of  $\text{ZnCl}_2$  or  $\text{I}$  on camphor (Armstrong a. Miller, *B.* 16, 2259; Montgolfier, *A. Ch.* [5] 19, 161).—3. By treating penta-methyl-benzene with  $\text{H}_2\text{SO}_4$  (Jacobsen, *B.* 19, 1216).—4. From mesitylene (or toluene),  $\text{MeCl}$ , and  $\text{Al}_2\text{Cl}_6$  (Jacobsen, *B.* 14, 2629; Claus a. Facking, *B.* 20, 3097; Friedel a. Crafts, *A. Ch.* [6] 1, 461).

*Properties*.—Oil. Gives on oxidation mellophanic acid  $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_2$  and three acids of the formula  $\text{C}_6\text{H}_2(\text{CH}_3)_2\text{CO}_2\text{H}$ .

*c-Durene*  $\text{C}_6\text{H}_3(\text{CH}_3)_3$ , [1:2:3:4]. *Prehnitene*, [ $-49^\circ$ ]. ( $204^\circ$  i. V.). Obtained by hydrolysis of its sulphonic acid, which is found amongst the products of the action of conc.  $\text{H}_2\text{SO}_4$  upon *s-durene* (Jacobsen, *B.* 19, 1211). It appears also to be formed by the action of  $\text{MeI}$  and sodium upon bromo- $\psi$ -cumene (Kelbe a. Pathe, *B.* 19, 1551). Formed also by the action of  $\text{H}_2\text{SO}_4$  on penta-methyl-benzene (Töhl, *B.* 21, 904). Dilute  $\text{HNO}_3$  oxidises it to  $\text{C}_6\text{H}_2(\text{CH}_3)_2\text{CO}_2\text{H}$ ; more energetic oxidation gives prehnitic acid  $\text{C}_6\text{H}_2(\text{CO}_2\text{H})_3$ . The picric acid compound crystallises from alcohol in yellow needles [ $95^\circ$ ]. *c-Durene* forms a di-bromo-derivative [ $210^\circ$ ], a nitro-derivative [ $61^\circ$ ], and a di-nitro-derivative [ $178^\circ$ ].

V. also Bromo-, Chloro-, and Nitro-DURENES.

*Durene dihydride*  $\text{C}_{10}\text{H}_{10}$ , ( $166^\circ$ ). In animal oil (Weidel a. Ciamician, *B.* 13, 73). Gives isophthalic acid on oxidation. Successive treatment with bromine and aniline converts it into cymene. The oil appears also to contain an isomeride ( $172^\circ$ ).

**DURENE CARBOXYLIC ACID v. TETRA-METHYL-BENZOIC ACID.**

**DURENE SULPHONIC ACID**  $\text{C}_6\text{HMe}_3(\text{SO}_3\text{H})$ . Obtained from Caucasian petroleum by sulphonation (Markownikoff a. Ogloblin, *A.* 234, 99). Formed, together with its chloride and di-duryl sulphone by treatment of powdered durene with  $2\frac{1}{2}$  pts. of  $\text{ClSO}_3\text{H}$  at  $0^\circ$ . Crystalline solid. V. sol. water, but pd. by  $\text{H}_2\text{SO}_4$ . When left to stand with  $\text{H}_2\text{SO}_4$  for 12 hours at  $50^\circ$  it is converted into hexa-methyl-benzene, *c-durene* sulphonic acid, and two  $\psi$ -cumene sulphonic acids. When distilled with dilute  $\text{H}_2\text{SO}_4$  hydrolysis begins as soon as, through evaporation of water, the temperature rises to  $120^\circ$  (Armstrong a. Mil-

ler, *C. J.* 45, 149). By fusion with  $\text{KOH}$  it gives durenol [ $117^\circ$ ].

*Salts*.— $\text{A}^+\text{Na}^+$ : pearly rhombic plates; v. sol. hot water, sl. sol. cold water, nearly insol. dilute  $\text{NaOH}$ .— $\text{A}^+\text{K}^+$ : thin rhombic plates, sl. sol. cold water.— $\text{A}^+\text{Ba}^+$ : pp. of small scales or rhombic plates, v. sol. hot water.— $\text{A}^+\text{Cu}^+$ : light blue six-sided tables; v. sl. sol. water.

*Chloride*  $\text{C}_6\text{HMe}_3(\text{SO}_3\text{Cl})$ : [ $99^\circ$ ]; glistening prisms; v. e. sol. ether, sl. sol. alcohol at  $0^\circ$ .

*Amide*  $\text{C}_6\text{HMe}_3(\text{SO}_2\text{NH}_2)$ : [ $155^\circ$ ]; long prisms (from alcohol) or long slender needles (from water); v. sol. hot, sl. sol. cold, alcohol, sl. sol. hot water, nearly insol. cold water (Jacobsen a. Schnapauff, *B.* 18, 2841; 19, 1210).

*u-Durene-sulphonic acid*  $\text{C}_6\text{H}_4(\text{SO}_3\text{H})$ . Plates or tables containing 2 aq. Prepared by dissolving isodurene in ordinary  $\text{H}_2\text{SO}_4$  at  $100^\circ$ – $120^\circ$ .

*Salts*.— $\text{A}^+\text{Na}^+$ : moderately sol. flat prisms.— $\text{A}^+\text{K}^+$  aq.— $\text{A}^+\text{Ba}^+$ : flat prisms, *B.* 57 at  $15^\circ$ .— $\text{A}^+\text{Ca}^+$  3 aq.— $\text{A}^+\text{Sr}^+$  9 aq.— $\text{A}^+\text{Pb}^+$  3 aq.— $\text{A}^+\text{Co}^+$  7 aq.— $\text{A}^+\text{Cu}^+$ .— $\text{A}^+\text{Ag}^+$ .

*Amide* [ $118^\circ$ ] (*J.*); [ $143^\circ$ ] (Kelbe a. Pathe, *B.* 19, 1553). Long fine needles, v. sol. alcohol, sl. sol. hot, nearly insol. cold, water (Bielecki, *A.* 193, 381; Jacobsen, *B.* 15, 1853).

*c-Durene sulphonic acid*  $\text{C}_6\text{HMe}_2(\text{SO}_3\text{H})$  [1:2:3:4:5]. *Prehnitene sulphonic acid*. Formed, together with other products, by the prolonged action of conc.  $\text{H}_2\text{SO}_4$  upon durene (*q. v.*) or its sulphonic acid. Small needles. Sparingly soluble in moderately dilute  $\text{H}_2\text{SO}_4$ .

*Salts*.— $\text{A}^+\text{Na}^+$  aq.: small glistening soluble tables.— $\text{A}^+\text{Ba}^+$ : small flat sparingly soluble crystals.

*Amide*  $\text{C}_6\text{HMe}_2(\text{SO}_2\text{NH}_2)$ : [ $187^\circ$ ]; small glistening prisms; sol. hot alcohol, sl. sol. cold (Jacobsen, *B.* 19, 1211). The same acid appears to be formed by the sulphonation of the product of the action of  $\text{MeI}$  and sodium upon bromo- $\psi$ -cumene; the amide of the acid so formed melts, however, at  $177^\circ$  (Kelbe a. Pathe, *B.* 19, 1552).

*Durene-di-sulphonic acid*  $\text{C}_6\text{Me}_2(\text{SO}_3\text{H})_2$ . Prepared by dissolving powdered durene in cold fuming sulphuric acid; on pouring the melt into ice and water the sulphonic acid crystallises out. It is much more stable than the mono-sulphonic acid, only being hydrolysed when steam is passed through the  $\text{H}_2\text{SO}_4$  solution, or when the salts are heated to  $170^\circ$  with  $\text{HCl}$ .

*Amide*  $\text{C}_6\text{Me}_2(\text{SO}_2\text{NH}_2)_2$ : [above  $310^\circ$ ]; small glistening crystals; sl. sol. alcohol (Jacobsen, *B.* 19, 1217).

**DURENOL**  $\text{C}_6\text{HMe}_3(\text{OH})$ , [ $117^\circ$ ]. ( $250^\circ$  i. V.). Formed by fusing sodium durene sulphonate with  $\text{KOH}$ . Large flat prisms. Sublimable and volatile with steam. Its *bromo-derivative*  $\text{C}_6\text{BrMe}_3(\text{OH})$  forms long glistening prisms, [ $118^\circ$ ]; its *nitro-derivative*  $\text{C}_6(\text{NO}_2)_3\text{Me}_3(\text{OH})$  yellow crystals, [ $130^\circ$ ]. By long melting with  $\text{KOH}$  it is converted into oxy-durylic acid  $\text{C}_6\text{HMe}_3(\text{OH})\text{CO}_2\text{H}$  [1:3:4:5:6] (Jacobsen a. Schnapauff, *B.* 18, 2843).

*Isodurenol*  $\text{C}_6\text{H}_4(\text{OH})$  [ $108^\circ$ ]. Colourless crystals. Prepared by fusing iso-durene-sulphonic acid with  $\text{KOH}$  (Jacobsen, *B.* 16, 1854).

*c-Durenol*  $\text{C}_6\text{H}(\text{CH}_3)_2(\text{OH})$  [1:2:3:4:5]. *Prehnitol*, [ $87^\circ$ ]. ( $266^\circ$  i. V.). From *c-durene* sulphonic acid by potash-fusion (Töhl, *B.* 21, 904).

Long silky needles (from ligroin); v. e. sol. alcohol and ether. Not coloured by  $\text{FeCl}_3$ . Gives a bromo-derivative [181°].

*Acetyl derivative*  $\text{C}_8\text{H}(\text{CH}_3)_2(\text{OAc})$ : [57°]; prisms.

**DURIDINE**  $\text{C}_8\text{H}(\text{CH}_3)_2(\text{NH}_2)$ . [14°]. (253°). S.G. 1.978. One of the products obtained by heating xylidine hydrochloride with MeOH (Hofmann, *B.* 17, 1913).— $\text{B}^+\text{HCl}$  (at 100°).— $\text{B}^+\text{H}_2\text{PtCl}_6$  (at 100°).

*Isoduridine*  $\text{C}_8\text{HMe}_2\text{NH}_2$ . *Amido-tetra-methyl-benzene*. (250° i. V.) at 740 mm. Formed by heating pseudocumidine or mesidine hydrochloride with methyl alcohol at 200°–300° (Nöling a. Baumann, *B.* 18, 1149). Colourless liquid, which solidifies in a freezing mixture.

Salts.— $\text{B}^+\text{HCl}$ : small white prisms.— $\text{B}^+\text{H}_2\text{Cl}_2\text{PtCl}_6$ : yellow tables.

*Acetyl derivative*  $\text{C}_8\text{HMe}_2\text{NHAc}$ : [211°]; white needles, v. sol. alcohol, sl. sol. water.

**DUROQUINONE**  $\text{C}_8\text{Me}_2\text{O}$ . [111°]. Prepared by reducing di-nitro-durene to durylene diamine with zinc-dust and acetic acid, removing the zinc by  $\text{H}_2\text{S}$ , and oxidising the solution with  $\text{FeCl}_3$ . Formed also by the action of warm  $\text{NaOH}$  aq upon  $\text{Me.CO.CO.Et}$  (Fechmann, *B.* 21, 1420). Long yellow needles. Sublimable. V. e. sol. ether, chloroform, benzene, alcohol, and acetone, v. sol. hot, but sl. sol. cold, ligroin. Reduced by zinc and  $\text{HOAc}$  to a substance [c. 210°], which is easily reoxidised to the quinone (Nef, *B.* 18, 2806; *C. J.* 53, 428; *A.* 237, 5).

**DUROYL-BENZOIC ACID** v. **TETRA-METHYL-BENZOYL-BENZOIC ACID**.

**DURYLIC ACID** v.  $\psi$ -CUMINIC ACID.

**Quinone of durylic acid** v.  $\psi$ -CUMOQUINONE CARBOXYLIC ACID.

#### DURYL METHYL KETONE

$\text{CH}_3\text{CO.C}_8\text{HMe}_2$  [1:2:3:4:6]. (254°). From, u-durene,  $\text{AcCl}$ , and  $\text{AlCl}_3$  (Claus a. Forsling, *B.* 20, 3098). Liquid. V. sol. alcohol and ether.

*Oxim*. [148°]. Small plates.

*Phenyl hydrazide* [215°]. Needles.

*s*-Duryl methyl ketone

$\text{CH}_3\text{CO.C}_8\text{HMe}_2$  [1:2:3:4:6]. (63°). (251°). From *s*-durene,  $\text{AcCl}$ , and  $\text{AlCl}_3$  (C. a. F.). Pearly plates.

*Phenyl hydrazide*. Small silky crystals; decomposing at 225°.

**DI-DURYL SULPHONE**  $\text{C}_8\text{HMe}_2\text{SO}_2\text{C}_8\text{HMe}_2$ .

*Sulpho-duride*. [37°]. Formed, together with durene sulphonic acid and its chloride, by the action of sulphuric chlorhydrin (2½ pts.) upon powdered durene at 0°. Long prisms. Can be distilled *in vacuo*. V. sol. alcohol, ether, benzene, and ligroin, insol. water (Jacobsen a. Schnapauff, *B.* 18, 2841).

**DYNAMITE** v. GLYCERIN.

**DYS-ALBUMEN** v. **PROTEIDS**.

**DYSLYSIN**  $\text{C}_{22}\text{H}_{32}\text{O}_8$ . [above 140°]. A product of the decomposition of cholic acid obtained either by heating it to 300° or by treating it with dilute  $\text{HCl}$  or  $\text{H}_2\text{SO}_4$  (Berzelius, *A.* 33, 139; 43, 1; Theyer a. Schlosser, *A.* 50, 235; Strecker, *A.* 67, 22; Hoppe-Seyler, *J. pr.* 89, 88). Amorphous resin, insol. water, sl. sol. boiling alcohol, sol. ether. Insol. alkalis. Named from its insolubility. Boiling alcoholic KOH reconverts it into cholic acid.

**DYSLYTE**  $\text{C}_8\text{H}_8\text{N}_2\text{O}_6$ . [189°]. S. 0.7 in 97 p.c. alcohol at 10°. Formed, together with eulyte, by treating citraconic acid with conc.  $\text{HNO}_3$  (Baup, *A.* 81, 102; Bassett, *Z.* 1871, 701). Long slender needles (from alcohol). Insol. water.

## E

**EARTHS.** The term *earths* is applied to the oxides of a number of the elements which are difficultly reducible to the metallic state. The majority of elements of this class are of very rare occurrence in the concentrated state, being found accumulated in but few minerals, such, for instance, as in *gadolinite*, *cerite*, *keilhauite*, *orthite*, *samaraskite*, *euxenite*, and a few other minerals. In minute quantities, however, the earths are disseminated throughout the whole mineral kingdom. Cossa has detected cerium and didymium in all classes of volcanic rocks; certain kinds of clays contain as much as one per cent. of cerium; and didymium may even be detected in sea-water by means of its absorption-spectrum. Yttria, an earth very rarely found in quantity, may be detected in almost every mineral species, in corals, and even in animal bones. Samarium, an element of the earth class, and even more rarely found in quantity than yttrium, seems to have the same ubiquitous character, and is not unfrequently found in appreciable traces in the minerals *celestine*, *strontianite*, and *native carbonate of lead*.

The oxides of the following elements are usu-

ally classed together as earths: *barium*, *strontium*, *calcium*, *magnesium*, *beryllium*, *aluminium*, *zirconium*, *titanium*, *thorium*, *lanthanum*, *didymium*, *cerium*, *yttrium*, *erbium*, *terbium*; and the more recently discovered elements, about the existence of some of which there is yet considerable doubt, *scandium*, *ytterbium*, *decipium*, *holmium*, *thulium*, *samarium*, *gadolinium*, and *dyprosium*.

From a chemical point of view some of these elements exhibit characteristics so widely different as to render it necessary to divide them into at least two groups; viz., those whose salts are not ppd. by ammonia, the hydrates being soluble in water and possessing a strongly alkaline reaction; and those ppd. by ammonia. To the first group belong barium, strontium, and calcium, whose oxides are termed the alkaline earths; all the others are ppd. by ammonia.

The analogies shown by the oxides of some of these elements with the oxides of the heavy and easily reducible metals would seem to throw them out of the list of earths; such are magnesium and beryllium; the existence of the stable oxides  $\text{MgO}$  and  $\text{BeO}$  seems to indicate

that these metals belong to the same group as cadmium and zinc. The same may be said of thorium, zirconium, and titanium, which constitute a natural group with tin, forming the oxides  $\text{MO}_2$ . As beryllium, thorium, zirconium, and titanium, are almost invariably found associated with the earths proper they are here retained in giving an outline of the chemical methods of effecting the separation of this numerous class of bodies from each other.

It is only within recent years that the list of earths has been so much extended, and there is every reason to believe that the number will be further increased, not so much, it may be, by finding that rare and ill-examined minerals contain new elements, as by discovering that some of the bodies already well known are in reality mixtures of two or more oxides; it is, however, to be remembered that the existence of all the oxides of elements enumerated above is not yet finally proved. The discoveries that have already been made in this field have proved the heterogeneous character of some well-known oxides or earths; this is exemplified below. This splitting up of an earth into two or more constituents is not to be looked upon as an act of *dissociation* (q. v.), but is merely the result of more refined methods of attacking the difficult problem of isolating the several already known earths in a state of purity, combined with a very close study of variations in their spectroscopic characteristics when the various elements are isolated from different mineral species. It is sufficient merely to glance over the discoveries that have been made relating to the earths, to understand the difficulties under which this branch of mineral chemistry labours, and upon what facts it is possible to assume, with any degree of certainty, the homogeneous or heterogeneous character of a material. Owing to the great similarity in the chemical reactions of many of the earths, to isolate any particular earth is a most tedious operation, as there are no known sharp methods, such, for instance, as for the separation of silver from copper, or copper from iron. When a pure material has been prepared the further chemical treatment of which fails to produce any variation in the atomic weight of the element, or in the depth of colour of the oxide, or in the intensity of any of the bands in the absorption-spectrum of the salts, it is assumed that the material is of a homogeneous character. But in preparing one particular earth it has been customary to select some mineral in which it predominates, and to purify the earth from all the others that contaminate it in small quantity. Even then only in one or two instances can it be asserted that the oxide is pure; in fact theoretical considerations show that to obtain a pure material by the methods employed is an impossibility. For example, samaria, which is undoubtedly a white oxide, is invariably tinted pale yellow because of a trace of adhering decipia, and the tint may be diminished in depth by numberless repetitions of fractional precipitation; so also yttria is tinted pale yellow by a trace of terbia, although Clève in one instance obtained a small quantity of a pure white colour; gadolina, doubtless a white oxide, has a pale yellow colour due to a trace of decipia; lanthana, a white oxide, can only with great difficulty be obtained free

from the last traces of praseodymia which colours it grey, although the absorption-spectrum shows no evidence of its presence. Inversely it may be assumed that those oxides which are coloured are more or less contaminated by the colourless ones, as terbia with yttria, decipia with gadolina and samaria, praseodymia with lanthana, and erbia with ytterbia and scandia. The chemical history of the earths indicates the above method of proceeding to be fallacious, and would seem to show that the only alternative is to isolate the same oxide from a number of different sources, and to examine if there are any differences in the physical characters of the different specimens; such as in the molecular weights, the depth of colour of the oxides, or in the intensity of the bands of the absorption-spectra. The advisability of this method is evident; for it is highly probable that two closely allied elements may exist in one mineral in such quantity as to make it appear to be a homogeneous substance, while the same material isolated from a different source by the same chemical methods may consist of the two oxides in such a totally different ratio as to show its complex character by discrepancies in the molecular weights, colour of the oxides, or the intensity of the bands in the absorption-spectra. This has indeed been found to be the case in several instances; yttria was usually considered to have a pale yellow colour, and this oxide and erbia were the only two oxides which Bunsen and Bahr, as well as Clève, could isolate from *gadolinite*, although Mosander had recorded the existence of a yellow or orange-coloured oxide, associated with these two, which he named terbia. In examining the yttria mineral *samariskite* found in North Carolina, L. Smith and Delafontaine observed that the yttria had a much deeper yellow tint than was usually ascribed to it when extracted from *gadolinite*, and these chemists ultimately succeeded in separating the orange-coloured oxide terbia from the white yttria. More recently De Boisbaudran, examining terbia from different sources, considered himself justified in asserting the existence of a number of oxides having an orange colour, showing no absorption-spectrum, but differing in molecular weights. As another instance: the salts of didymia obtained from *cerite* show a very characteristic absorption-spectrum; Delafontaine, when examining the spectrum of the didymia from *samariskite*, observed that the bands in the blue region of the spectrum differed from those shown by the didymia from *cerite*; and De Boisbaudran, working upon this material from *samariskite*, eliminated the oxide of the element giving the blue bands and gave the element the name samarium. The great preponderance of didymia over samaria in *cerite* had previously masked the existence of the latter, whereas in *samariskite* samaria is relatively abundant compared with didymia, and shows its presence at once by the absorption-spectrum. Marignac again, in examining erbia, discovered that by many repetitions of the process of fractional decomposition of the nitrate by fusion, the pink material yielded a more easily decomposable salt of a white colour, and named the oxide ytterbia; and Nilson, preparing this white oxide ytterbia from erbia, found that the molecular weight differed from Marignac's material, and this he ultimately found to be due to the presence of another

white oxide whose nitrate is more readily decomposed by heat than ytterbia; this white oxide Nilson has called scandia. Clève, studying the absorption-spectra of different fractions of erbia, concluded that this oxide is really a mixture of three, the true erbia, and two others which he has called holmia and thulia. Holmia has been examined by De Boisbaudran (*C. R.* 102, 1003) by fractional ppn. of the sulphate by alcohol; it appears to consist of two oxides, holmia, and one which he names dysprosia, both showing absorption-spectra. Finally, the most striking discovery relating to the earths is that made by Von Welsbach (*M.* 5, 508). This chemist has found that by crystallising a mixture of the nitrates of didymium, lanthanum, and ammonium in an acid medium, certain double salts are formed, the fractional crystallisation of which, repeated several hundred times, results in the separation of didymium into two elements, one forming green-coloured salts, hence named *praseodymium*, and the other forming salts of an amethyst colour; this second element Von Welsbach calls *neodymium*; these elements show absorption-spectra of a totally different character. This is a most remarkable discovery when it is considered how much labour Clève and others have given to the preparation of pure didymia and its salts by fractional ppn. without apparently observing any facts to indicate its complex character; and more particularly as one constituent gives green-coloured salts, whereas didymium salts have always been recorded as possessing a red or pink colour (*v. Didymium*, p. 383).

The foregoing facts show how necessary it is to isolate a particular earth from several minerals which contain it in large as well as small quantity, before it can be asserted to be a homogeneous body; and when several specimens have been obtained, the absorption-spectra, the atomic weights of the elements in each, and the depth of tint of the oxides, must agree in all the specimens. Krüss and Nilson (*B.* 20, 2131) have worked upon several minerals, and in particular upon large quantities of *Fergusonite*, and from a study of the absorption-spectra of various solutions they conclude that samarium, erbium, neodymium, praseodymium, and other bodies showing absorption-spectra and considered to be elementary, are in reality of a complex character and consist each of a large number of elements. This result is arrived at judging only by the variations in intensity of the absorption-bands, but it would be premature to attach much weight to the assertions of these chemists until fairly pure specimens of the various bodies have been isolated from the several sources, for it is not improbable that in a mixture of a large number of elements, the absorption-bands of one may influence the intensity of those of another.

The following list of elements comprises the metals of those earths which have as yet been prepared in a fairly pure state, although a few are, as aforesaid, looked upon by some chemists as mixtures of several earths.

Aluminium	Yttrium	Lanthanum
Beryllium	Erbium	Neodymium
Zirconium	Terbium	Praseodymium
Thorium	Holmium	Samarium
Scandium	Dysprosium	Cerium
Ytterbium	Thulium	Gadolinium.
	Decipium	

Those elements whose salts show absorption-spectra are erbium, holmium, dysprosium, thulium, neodymium, praseodymium, and samarium. The oxides are all white, with the exception of erbia which is pink; holmia and thulia, pink (?); decipia, orange; neodymia, blue (Von Welsbach); praseodymia, dark brown; ceria, pale yellow; gadolina, white (pale yellow, Marignac); terbia, orange.

The chemical methods for effecting the individual separation of the earths are either by fractional fusion of the nitrates, or fractional ppn. with dilute ammonia; those oxides which are ppd. by  $K_2SO_4$  (*v. post*) are all much more basic than those not so ppd., and the order of basicity of the two groups is as follows, beginning with the most basic (assuming the existence of the bodies enumerated as distinct earths):—

and for the yttria group,

An oxide is regarded as more or less basic than another according as it is displaced from its salts with more or less difficulty than the other oxide. The relative basicities of two oxides are determined by fractionally ppg. a solution containing salts of both oxides. Thus if an insufficiency of a pptant. is added to a mixture of two earths in solution in the ratio  $\frac{A}{B}$ , and the pp. contains the

earths in the ratio  $\frac{a}{b}$ , then A is said to be more or

less basic than B according as the ratio  $\frac{a}{b}$  is

$< \text{or} > \frac{A}{B}$ ; the less basic earth yields more easily

to the pptant., the more basic resists its action more.

In the cerite earths, decipia, being the least basic, accumulates in the first pps. and lanthana remains in solution; while in the yttria group, scandia and yttria stand at the two extremes. The oxides ceria, thoria, zirconia, and beryllia, as well as alumina, are easily separated by methods other than fractional ppn. or fusion.

The sources from which the earths are obtained are few. The best known mineral containing these oxides, and apparently the most abundant, is *cerite*, which consists largely of ceria, with about 15 p.c. of lanthana, praseodymia, and neodymia; the amount of samaria and decipia is small, being about three-tenths p.c.; gadolina only a trace; and there is generally a small quantity of the yttria group of earths. *Gadolinite* and *euxenite* are each rich in yttria, erbia, holmia, with a small quantity of ytterbia and scandia; while *saxarshite* appears to be the most abundant source of terbia, samaria, and gadolina, together with much yttria.

SEPARATION OF THE EARTHS.—Before attempting to isolate the earths individually, they are first separated as completely as possible from the heavy metals and the alkaline earths, and from niobic, tantallic, and titanic acids; fusing the finely ground mineral, should it be a niobate or tantalate, with  $KHSO_4$ , and digesting with water, will leave  $Nb_2O_5$  and  $Ta_2O_5$  insoluble; if the mineral is a silicate, like *cerite* or *gadolinite*,  $HClAq$  or  $H_2SO_4Aq$  may be employed to decompose it. The Cu, Bi, &c., in the solution are

ppd. by  $\text{SH}_2$ , and ammonio oxalate is added; if the oxalate is in large excess the filtrate will contain the zirconia as well as beryllia and alumina. The mixed oxalates are well washed, dried, and strongly heated, and the oxides thus formed are dissolved in  $\text{HClAq}$ ; the evolution of  $\text{Cl}$  indicates the presence of  $\text{CeO}_2$ ; if the heating has been too intense,  $\text{ZrO}_2$  and  $\text{ThO}_2$  remain insoluble. The solution is ppd. by ammonia, and boiled to separate  $\text{CaO}$ ,  $\text{BaO}$ , and  $\text{SrO}$ ; the pp. is redissolved, ppd. by oxalic acid, and the oxalates are heated. The colour of the strongly heated material will now give some indication of its character. It is invariably of a deep brown or pale yellow colour; the former indicates the presence of much didymia (neodymia and praseodymia), and the latter tint indicates terbia, decipia, or ceria; the colouring materials didymia, terbia, and decipia appear to be peroxides which are reduced and become white, or greenish white, when gently heated in a reducing atmosphere.

The oxides are dissolved in nitric acid; the solution is mixed with three or four times the weight of the oxides of sodic nitrate, evaporated to dryness, and the residue is subjected to gentle fusion to decompose the ceric, thoracic, and zirconic nitrates, should these bodies be present; water is added and the liquid is filtered. The spectroscopic will now readily reveal the presence of didymia, erbia, and such other earths as show absorption bands; the bands of samaria are very faint and a somewhat conc. solution is required.

The next step in the separation of the earths is to divide them into two groups by ppg. the solution, either as chlorides, nitrates, or sulphates, by  $\text{K}_2\text{SO}_4$ . To the nearly neutral solution more than sufficient  $\text{K}_2\text{SO}_4$  is added in fine powder to saturate the liquid, which is then allowed to stand some hours with occasional agitation; the pp. that forms is filtered off and washed several times with a saturated solution of  $\text{K}_2\text{SO}_4$ , the operations being done cold. The pp. and solution now contain the following elements:—

*Precipitate.*

Di, La, Ce, Sm, Dp, Th, Zr, Gd;

*Filtrate.*

Y, Yb, Er, Ho, Tm, Tb, Sc.

The pp. of Gd-salt is slightly soluble in a saturated solution of  $\text{K}_2\text{SO}_4$ , but for the other elements the separation is practically perfect (*v. post*). Both pp. and filtrate are decomposed with caustic soda, the pps. are well washed till free from sulphates, and both are redissolved separately in  $\text{HNO}_3\text{Aq}$ ; if much Ce, Yr, or Th is suspected, the pp. from the solution is again fused with sodic nitrate as before.

The earths  $\text{Di}_2\text{O}_3$ ,  $\text{La}_2\text{O}_3$ , &c., are separated from each other by fractional ppg. of their nitrates by cold dilute ammonia: to the dilute neutral solution sufficient ammonia is added to ppt. a considerable portion of the whole, say about nine-tenths; the pp.<sup>o</sup> is filtered off, redissolved in nitric acid, and again ppd. in about the same proportion as before, the operation being repeated upon each pp. till about only one-tenth of the original material remains. All the filtrates are put together, and the operations

are repeated as before, and the final small pp. is added to the previous one. The success of this method of operating depends upon the slight differences between the basicities of the various earths, the least basic tending to be ppd. first, and the most basic to remain in solution. The basic powers are, in order of increasing magnitude  $\text{Dp} < \text{Gd} < \text{Sm} < \text{Nd} < \text{Prd} < \text{La}$ ; therefore the  $\text{La}_2\text{O}_3$  tends to accumulate in the filtrates, and the  $\text{Dp}_2\text{O}_3$ ,  $\text{Gd}_2\text{O}_3$ , and  $\text{Sm}_2\text{O}_3$  in the pps. The absorption-spectrum will show that the intensity of the  $\text{Nd}_2\text{O}_3$  and  $\text{Prd}_2\text{O}_3$  bands becomes less, and the colour of the oxide obtained by heating the oxalate becomes more nearly white, in the first filtrates as the process is repeated; the least basic material will do the same, inasmuch as  $\text{Gd}_2\text{O}_3$  and  $\text{Sm}_2\text{O}_3$  are white and  $\text{Dp}_2\text{O}_3$  is orange yellow, whereas the intermediate fractions rich in  $\text{Nd}_2\text{O}_3$  and  $\text{Prd}_2\text{O}_3$  give very strong absorption-bands, and the strongly heated oxalates are of a deep coffee-brown colour. The difference between the basicity of  $\text{La}_2\text{O}_3$  and the other earths is much greater than that between any of the other two consecutive earths of the series, as  $\text{Dp}$ - $\text{Gd}$ ,  $\text{Gd}$ - $\text{Sm}$ ,  $\text{Sm}$ - $\text{NdPrd}$ , so that the purification of  $\text{La}_2\text{O}_3$  is easy compared with the labour required for the separation of the others. Assuming that the less basic material is obtained free from  $\text{Nd}_2\text{O}_3$  and  $\text{Prd}_2\text{O}_3$ , as shown by the spectroscopic, fractional pptn. is repeated on the material till the filtrates give an oxide of a white colour consisting of  $\text{Sm}_2\text{O}_3$  and  $\text{Gd}_2\text{O}_3$ , which are separated from each other by taking advantage of the greater solubility of the double sulphate of gadolinium and potassium in a conc. solution of  $\text{K}_2\text{SO}_4$ .

Another method of conducting the separation of the earths consists in using a number of flasks in series, the central one being marked '0,' those to the right marked +1, +2, +3, &c., and those to the left -1, -2, -3, &c. The solution to be fractionated is placed in the central flask marked '0,' and about one-half of the material is ppd.; the pp. is dissolved and placed in -1, and the filtrate is placed in +1. One half of -1 is ppd., the pp. is dissolved and put into -2, and the filtrate into 0; one half of +1 is thrown down, the pp. is dissolved and placed in 0, and the filtrate is put into +2. In this way the operations are repeated till the + $n$  flask contains the most basic earths, and the - $n$  flask the least basic.

The earths not ppd. by  $\text{K}_2\text{SO}_4$ , consisting of  $\text{Y}_2\text{O}_3$ ,  $\text{Er}_2\text{O}_3$ ,  $\text{Tb}_2\text{O}_3$ , &c., are converted into nitrates and are treated by either of two methods—(1) by fusing the nitrates, or (2) by fractional ppg. with dilute ammonia. The first method would seem to be the more successful, as by its use scandia, ytterbia, holmia, thulia, and erbia have been isolated. The basicities of the earths being in the order  $\text{Sc} < \text{Yb} < \text{Er} < \text{Ho} < \text{Sm} < \text{Tb} < \text{Y}$ , the nitrate of scandia tends to decompose at a lower heat and more readily than the ytterbia salt, the latter decomposes before erbia, holmia, &c., and these decompose more readily than yttrio nitrate. Hence, if the fusion has been carried nearly to complete decomposition, the fused mass when treated with water will give a solution rich in yttria and terbia, and containing little or no scandia and ytterbia. The insoluble material is redissolved in nitric acid, and again

subjected to fusion as before; the fused mass is treated with water and filtered, the operations being repeated very many times, as in fractional ppn.

The methods given above for separating the earths may be somewhat modified according as one or other of the elements preponderates. In working with the cerite earths the material, as nitrates, is first mixed with sodic nitrate, and subjected to the process of fusion to decompose the very large amount of ceric nitrate present; as the amount of the yttria earths in cerite is small, the solution from the insoluble ceric oxide may at once be treated by fractional ppn.; the yttria earths, being very much less basic than  $\text{La}_2\text{O}_3$  or  $\text{Di}_2\text{O}_3$ , collect completely with the  $\text{Sm}_2\text{O}_3$  in the first fractions, when this portion is then separated by  $\text{K}_2\text{SO}_4$ . Again, in such minerals as *gadolinite* or *samaraskite*, the amount of the cerite earths being small, fractional ppn. or fusion may be at once resorted to with the nitrates, and the most basic portions, containing all the La, Di, Sm, &c., may be finally treated with  $\text{K}_2\text{SO}_4$ .

Several methods of limited application are suitable for the separation of a few of the earths; didymia, containing a trace of lanthana, may be purified by ppn. in a strongly acid solution ( $\text{HNO}_3$ ) with oxalic acid, lanthanic oxalate being much more soluble than the didymic salt; the same process may be employed for separating yttria from terbia, the oxalate of the former being the more soluble; or this separation may be effected by dissolving the oxides in formic acid, and crystallising, the terbic formate being the less soluble. Small quantities of cerium are easily separated by ppg. with large excess of soda, and passing chlorine through the liquid, which leaves the  $\text{CeO}_2$  insoluble.

The distinguishing characteristics of the elements scandium, ytterbium, and yttrium are their widely different atomic weights, different spark-spectra, and the slight differences in basicities, these being in the order  $\text{Sc} < \text{Yb} < \text{Y}$ . Erbia, holmia, and thulia are recognised by the bands in their absorption-spectra; deicipia and terbia both give orange-coloured oxides, but differ in the fact that the former is ppd. by  $\text{K}_2\text{SO}_4$  as a double sulphate, while the latter is not so ppd.; gadolina and samaria, two closely-allied earths, differ also in the solubility of their double sulphates with  $\text{K}_2\text{SO}_4$  in a conc. solution of this salt, and the former gives no absorption-spectrum.

The earths, known as rare, resemble alumina in being ppd. by ammonia, insoluble in excess, but differ from alumina in being insoluble in excess of soda or potash; they likewise resemble  $\text{CaO}$ ,  $\text{SrO}$ , and  $\text{BaO}$  in forming, with the exception of  $\text{ZrO}_2$ , oxalates which are insoluble in water and oxalic acid or ammonium oxalate, but are slightly soluble in acids;  $\text{ThO}_2$  and  $\text{ZrO}_2$  are ppd., like  $\text{Al}_2\text{O}_3$ , by sodium thiosulphate. The oxides of the cerite and yttria groups are all assumed to have the formula  $\text{M}_2\text{O}_3$ ; most of them form higher oxides by ppg. with ammonia in presence of  $\text{H}_2\text{O}_2$ . Our knowledge of the rare earths is yet very incomplete.

J. J. H.

**EARTHS, METALS OF THE.** The term *earths* is one of those words which perpetuate the connexion of chemistry with alchemy. The meaning given to the term at different periods

marks the change from the vague conceptions of the earlier times to the more precise knowledge regarding composition and properties which belongs to modern chemistry. *Earth* was one of the four alchemical essences or elements. In later times the term was applied to all bodies which were insoluble in water and not changed by heat. 'Terra est corpus fossile,' says Boerhave, in his *Elementa Chemia* (1732), 'simplex, durum, friabile, in igne fixum, in igne non fluens, in aqua, alcoholio, oleo, aëre dissolvi non potens.' As investigation advanced, a separation was made between bodies which had many properties of earths and yet were soluble in water—these were called the alkaline earths—and bodies which were not dissolved by water. Silica, alumina, gypsum, and ferric oxide, were taken to be the typical earths. Lavoisier's demonstration of the change which occurs when a metal is burnt suggested that many earths might be oxides of metals; Davy's discovery of sodium and potassium marked a further step in the acquisition of accurate knowledge of the composition of earths; and the labours of Berzelius and his followers completed the work which the alchemists began.

The earths are the oxides of certain metals; these oxides are all insoluble, or only slightly soluble, in water; the oxides are reduced to metals with difficulty. There is still difference of opinion as to the list of metals whose oxides are to be included in the class of earths, but the matter is not one of great importance. The term is used in the present article only for convenience of classing together a number of elements which show distinct analogies. The metals Al, Ga, In, Sc, Y, La, and Yb resemble each other in so many respects that it is advisable to place them in the same class; thallium also shows distinct analogies with Al, Ga, and In; and the eight elements mentioned more or less resemble the non-metallic element boron.

These nine elements form Group III. in the periodic classification of the elements. This group is divided as follows:—

#### Group III.

##### Even series

2	4	6	8	10	12
B(11)	Sc(41)	Y(89)	La(139)	Yb(173)	—

##### Odd series

3	5	7	9	11
Al(27)	Ga(69.9)	In(114)	—	Tl(204)

These elements are all metallic except boron; scandium and ytterbium have not been isolated; some of the properties of those metals of this group which have been isolated are presented in the table on the next page.

**Chemical properties.**—The earth-metals decompose water, some of them at ordinary temperatures, e.g. Y and La, others at  $100^\circ$ , e.g. Al, and others only at red heat, e.g. Tl. They are all oxidised when heated in oxygen, Al and Ga not at all readily; Tl is oxidised even by exposure to air. The metals combine directly with the halogens to form compounds  $\text{MX}_3$ , and Tl forms also the gasifiable chloride  $\text{TlCl}$ .

The well-marked oxides of the metals we are considering belong to the form  $\text{M}_2\text{O}_3$ , but Tl also forms the very characteristic oxide  $\text{Tl}_2\text{O}$ ; the oxides  $\text{M}_2\text{O}_3$  are basic,  $\text{Tl}_2\text{O}$  is distinctly alka-

	ALUMINIUM	GALLIUM	YTRIUM	INDIUM	LANTHANUM	THALLIUM
Atomic weights	27.02	69.9	89.6	113.4	138.5	203.64
	One or more compounds of each element, except Y and La, have been gasified; specific heats have been directly determined, except for Y. Molecular weights unknown.					
Melting points	700°	30°	(?)	176°	(?)	285°
Specific gravities (approx.)	2.6	6.1	(?)	7.3	6.2	11.9
Specific heats	.225	.08	(?)	.057	.047	.034
Occurrence and preparation	Very widely distributed, chiefly as silicate. Obtained by reducing $\text{AlCl}_3 \cdot 2\text{NaCl}$ by Na	In very small quantities, as sulphide, in some zinc blendes. Obtained by electrolysis of alkaline solution of the sulphate.	With Sc, Yb, La, &c., as silicate in a few rare Swedish minerals. Obtained by reducing $\text{Y}_2\text{Cl}_6 \cdot 2\text{NaCl}$ by Na, or by electrolysis.	In very small quantities, as sulphide, in some zinc ores. Obtained by reducing oxide by C or H, or ppg. solutions of salts by Zn.	With, Y, Yb, Ce, &c., as silicate in a few rare Swedish minerals. Obtained by reducing $\text{La}_2\text{Cl}_6$ by K, or by electrolysis of molten $\text{La}_2\text{Cl}_6 \cdot 2\text{NaCl}$ .	In small quantities, chiefly as cerite, fairly widely distributed. Obtained by electrolysis of salts in solution; by ppg. by Al or Zn; or by reducing oxide by KCN or C.
Physical properties	Tin - white, fairly hard, very malleable and ductile, very sonorous.	Silver-white, fairly hard, rather brittle, very low melting-point.	Greyish-powder (little investigated).	White, very soft, lustrous.	White-grey, fairly hard, and ductile.	Very lustrous, malleable and ductility small, very soft.

line, forming the hydroxide  $\text{TlOH}$ , which is undoubtedly to be classed with the alkalis. The most characteristic salts of the metals of the earths belong to the form  $\text{M}_3\text{X}$ , where  $\text{X} = \text{SO}_4, \text{SO}_3, \text{CO}_3, 2\text{NO}_3, 2\text{ClO}_3, \frac{2}{3}\text{PO}_4$ , &c.; Tl also forms very characteristic salts,  $\text{Tl}_2\text{X}$ , closely resembling those of the alkali metals. The sulphates  $\text{M}_2\text{SO}_4$  of the odd-series members of the group, except Tl, i.e. the sulphates of Al, Ga, and In, combine with alkali sulphates to form alums  $\text{M}_2\text{SO}_4 \cdot \text{X}_2\text{SO}_4 \cdot 24\text{H}_2\text{O}$ , where  $\text{M} = \text{Al, Ga, or In}$ , and  $\text{X} = \text{alkali metal usually K or NH}_4$ ; thalious sulphate  $\text{Tl}_2\text{SO}_4$  forms an alum in which it takes the place of the alkali sulphate ( $\text{Al}_2\text{SO}_4 \cdot \text{Tl}_2\text{SO}_4 \cdot 24\text{H}_2\text{O}$ ). In the three elements, Al, Ga, In, the tendency to form more than one chloride increases as the atomic weight increases, and also the tendency of the chloride  $\text{M}_2\text{Cl}_4$  to dissociate into  $\text{MCl}_3$  increases as the atomic weight increases. Al, Ga, and Y dissolve in  $\text{KOH}$  with evolution of  $\text{H}_2$ ; in this respect they show analogies with some of the non-metals. Tl appears to form an oxide  $\text{Tl}_2\text{O}_3$ , and this oxide seems to be acidic. The chlorides  $\text{AlCl}_3, \text{GaCl}_3$ , and  $\text{InCl}_3$  exist as gases at very high temperatures; there is evidence of the existence as gases of  $\text{GaCl}_2$  and  $\text{InCl}_2$ , and possibly of  $\text{InCl}$ ;  $\text{TlCl}$  has been gasified, but  $\text{TlCl}_2$  is known only as a solid. These data seem to indicate that the atoms of the earth-metals are trivalent, and perhaps also divalent, in gaseous molecules.

The investigation of the earth-metals is yet

very incomplete; so far as facts are available one may say that Al, Ga, and In are very closely related, that Sc, Y, La, and Yb form another family, and that Tl shows relations with the Al family, but is also most distinctly analogous to the alkali metals on one hand and lead on the other hand. Boron, which is the non-metallic member of Group III, has already been considered (v. vol. i. p. 521). M. M. P. M.

#### ECBOLINE or ERGOTININE.

**ECGONINE**  $\text{C}_8\text{H}_{11}\text{NO}$ , i.e.  $\text{C}_8\text{H}_9\text{Me.CH(OH).CH}_2\text{CO}_2\text{H}$ . *tryoxon*, offshoot. Tetrahydride of Tetrahydro- $\beta$ -oxy-methyl- $\beta$ -pyridyl-propionic acid. [198°]. Obtained, together with benzoic acid and MeOH, by heating cocaine ( $\text{C}_8\text{H}_9\text{Me.CH(OBz).CH}_2\text{CO}_2\text{Me}$ ) with  $\text{HCl}$  at 100° (Wohler, A. 121, 372; Lossen, A. 133, 351). Boiling baryta, acting on cocaine, forms not only ecgonine but also 'isotropine'  $\text{C}_8\text{H}_{11}\text{NO}$  (Calmels a. Gossin, C. R. 100, 1143). Monoclinic prisms (containing aq) (from alcohol);  $a:b:c = .8136:1:6277$ ;  $\beta = 87^\circ 8'$ . V. sl. sol. water, m. sol. alcohol, insol. ether.

• *Reactions*.—1. The product obtained by heating with  $\text{MeI}$  gives, after warming with silver chloride and Ag, a methyl- $\alpha$ -chloride, whence ( $\text{C}_8\text{H}_9\text{Me.CH}_2\text{CO}_2\text{H}$ ),  $\text{PtCl}_4$  may be obtained (Gintl a. Storch, M. 8, 78).—2. Oxidation with  $\text{KMnO}_4$  gives succinic acid (Einhorn, B. 21, 50).—3. Heating with  $\text{H}_2\text{SO}_4$  forms an anhydride (?), whose barium salt  $\text{C}_8\text{H}_9\text{BaN}_2\text{O}_4$  is crystalline (Calmels

a. Gossin, *C. R.* 100, 1143).—4. Distillation with BaO gives methylamine.

**Salts.**— $B'H_3PtCl_4$  [226°]; yellow powder, extremely sol. water, sl. sol. alcohol. When its solution is heated there is formed  $B'PtCl_3$  as yellowish needles, v. sol. water, nearly insol. alcohol (C. a. G.).— $B'HCl$  [246°]. Sl. sol. alcohol (Liebemann, *B.* 21, 2351).

**Benzoyl derivative**  $C_9H_9O_2NBz$  [189°] (M.); [192°] (S.); [195°] (L. a. G.). Formed as a by-product in the preparation of cocaine (Merck, *B.* 18, 1594). Formed also by boiling cocaine with water for several hours (Einhorn, *B.* 21, 47). Also from ecgonine and  $Bz_2O$  (Liebemann a. Giesel, *B.* 21, 3196). Flat colourless prisms; sol. water and alcohol, nearly insol. ether. Crystallises also in prisms containing 4aq [92°] and [140°]. Decomposed by HCl into benzoic acid and ecgonine. Partially converted by MeI, dissolved in MeOH in presence of alkali into cocaine, although the greater part is simply resolved into benzoic acid and ecgonine (Skraup, *M.* 6, 556; cf. Merck, *B.* 18, 2264). In the same way, by heating benzoyl-ecgonine with alkyl iodides, the following homologues of cocaine may be prepared, ethyl-benzoyl-ecgonine  $C_{11}H_{15}EtNO_2$  [108°]; monoclinic prisms; propyl-benzoyl-ecgonine  $C_{14}H_{19}PrNO_2$  [79°]; and isobutyl-benzoyl-ecgonine  $C_{14}H_{19}(CH_3Pr)NO_2$  [82°] (Novy, *Ph.* [3] 18, 233). According to Einhorn (*B.* 21, 3443) the first of these homologues of cocaine is a liquid and the second a solid [58°].

Salt of Benzoyl-ecgonine  $B'HAuCl_4$ : sparingly soluble golden leaflets.

**Anhydro-ecgonine**  $C_8H_9NO_2$ , i.e.  $C_8NH_9Me.CH.CO.H$  [235°]. Formed by the action of  $PCl_5$  (Merck, *B.* 19, 3002) or  $POCl_3$  (Einhorn, *B.* 20, 1221) on ecgonine. Crystals, v. sol. water and alcohol, almost insol. other solvents. With Br it forms  $C_8H_9Br_2NO_2$ , whose hydrochloride  $C_8H_9Br_2NO_2.HCl$  melts at 184°. It forms a perbromide [158°].

**Salts.**— $B'HCk$  [241°].— $B'H_3PtCl_4$  [223°].— $B'HAuCl_4$ .— $B'HI$  [186°].— $B'HIr$  [155°].

**Ethyl derivative**  $C_9H_9EtNO_2$ . Oil. Forms a hydrochloride [244°].— $B'H_3PtCl_4$  [211°].

**ECHICERIN** v. DITA BARK.

**ECHITIN** v. DITA BARK.

**ECHITENINE** v. DITA BARK.

**EFFLORESCENCE.** The formation of a loose powdery deposit on the surface of a solid body is termed *efflorescence*. Some hydrated salts lose water of crystallisation by exposure to the air, and the surface becomes covered with a deposit of the dehydrated salt; crystals of  $Na_2CO_3 \cdot 10H_2O$ , for instance, effloresce in this way, the surface becoming  $Na_2CO_3 \cdot 6H_2O$ . If a porous body is filled with a salt solution, the solution will be drawn by capillary action to the surface of the solid, and if the body in solution crystallises on the surface of the solid the phenomenon is called *efflorescence*; thus, the formation of nitre on the surface of the soil, or of sodium carbonate on walls, is an example of efflorescence. The term is also applied to the creeping of a solution up the sides of a vessel and deposition of the dissolved body; thus, if a solution of sal ammoniac is exposed to the air, crystals are formed where the surface of the liquid touches the sides of the vessel; the liquid then rises, by capillary

action, between these crystals, and more crystals are formed above the first layer, and so on.

M. M. P. M

**EGG ALBUMEN** v. PROTEIDS.

**EICOSANE** v. ICOSANE.

**ELCOCMARGARIC ACID**  $C_{17}H_{33}O_2$  [48°]. Occurs as glyceride in the oil from the seeds of *Elaeococca Vernicia* (Clôez, *C. R.* 81, 469; 82, 501; 83, 943). Trimetric tables v. e. sol. ether. Absorbs oxygen from the air, becoming resinous. Sunlight converts the oil of *Elaeococca* into a solid fat, which on saponification gives elaeostearic acid [72°].

**ELÉOPTENE.** The portion of a natural essential oil that does not readily solidify.

**ELAIDIC ACID.** The solid polymeride obtained by the action of nitrous acid on Oleic acid (q. v.).

**ELAIDIN.** The solid polymeride of Olein, v. Oleic acid.

**ELASTIN** v. PROTEIDS, Appendix C.

**ELATERIN**  $C_{10}H_{15}O_2$ . Occurs in the spurring cucumber (*Momordica Elaterium*) (Zwenger, *A.* 43, 359; Morrus, *A.* 2, 366; Power, *Ph.* [3] 5, 645). Hexagonal tables, insol. water, sl. sol. ether, v. sol. alcohol. Purgative. Gives a carmine colour with phenol and  $H_2SO_4$  (Lindo, *Fr.* 17, 500; cf. Johansson, *Fr.* 24, 156).

**ELECTROLYSIS.** The separation of a compound into parts effected by the passage of an electric current. A compound which is decomposed by the passage through it of an electric current is called an *electrolyte*; the parts into which it is separated are called the *ions*. When different electrolytes are decomposed by a current, the masses of the ions which carry with them equal quantities of electricity are in the proportion of the chemical equivalents of these ions. Conversely the masses of several ions which are chemically equivalent produce equal quantities of electricity by their combination with other ions; thus, suppose 32.7 grams of zinc were dissolved in sulphuric acid, 28 grams of iron in hydrochloric acid, and 9 grams of aluminium in potash, the quantity of electricity set in motion by each action would be the same. The electricity behaves as if it were divided into atoms, one of which is attached to each monovalent ion, two to each divalent ion, and so on.

In some cases electrolysis proceeds as if the mass of the electrolyte expressed by its chemical formula were being separated into ions; in other cases the action proceeds as if the mass of electrolyte decomposed by the current were a multiple of that expressed by the formula. There are some binary compounds which are not electrolytes, but which undergo electrolysis when mixed with other compounds that also are not themselves electrolytes. The application of the facts of electrolysis to chemical processes will be dealt with in the art. **PHYSICAL METHODS.**

M. M. P. M.

**ELECTRONEGATIVE** and **ELECTROPOSITIV**. When a binary salt is electrolysed into its elements, one of the elements separates at the negative electrode and the other at the positive electrode; the former element is said to be electropositive towards the latter. An element may be electropositive towards another element and at the same time electronegative towards a third element; thus in the electrolysis of a

metallic sulphide the sulphur will separate at the positive electrode, but in the electrolysis of sulphur chloride the sulphur separates at the negative electrode; sulphur is negative towards metals but positive towards chlorine. The terms electropositive and negative are used in chemistry as practically synonymous with the terms basylous and chlorous. The classification of elements into positive and negative is of use, inasmuch as with this property a number of others are associated; thus, if we know that an element is positive to many others we conclude that its chemical properties are those characteristic of metals; if, on the other hand, the element is negative to a number of metals, we conclude that its oxides will be acidic, that it will not form salts by replacing the hydrogen of acids, that it will possibly form a hydride, and that generally it will be characterised by non-metallic properties.

M. M. P. M.  
**ELEMENTS.** Although the notion of an element or elementary body is one of the remotest antiquity, it has reached its present form by a process of slow growth. The Aristotelian elements—earth, water, air, and fire—represented properties or conditions rather than actual substances; and the same may be said of the alchemical elements—salt, sulphur, and mercury. A very casual review of the older chemical writings will show that these conceptions were scholastic rather than scientific, and yet they served their purpose in a primitive way and aided to some extent in the classification of material things. In a strictly chemical sense, the modern idea of an element, together with its implied distinction between elementary and compound bodies, seems to have originated with Boyle, who, in his *Sceptical Chymist* and other essays, vigorously combated the earlier notions. He taught that such substances were to be regarded as elementary as were not capable of further separation, and which, being obtainable from compounds, could yield like compounds again. Such elements, however, he did not specifically define, nor did he assign any positive limit to their number.

From this point the conception of chemical elements slowly developed, changing as the resources of analysis changed, becoming more definite with the introduction of quantitative methods into chemistry, until with the decomposition of the alkalis and alkaline earths by Davy, and the discovery of the true nature of chlorine, it crystallised into its present form. To-day the myriads of known substances are all capable of ultimate analysis, and they are reduced at last to about sixty-nine or seventy simple bodies, which resist all efforts of the analyst to decompose them further. These simple bodies, or elements, are as follows:—

Aluminium	Carbon	Gold
Antimony	Cerium	Hydrogen
Arsenic	Chlorine	Indium
Barium	Chromium	Iodine
Beryllium	Cobalt	Iridium
Bismuth	Copper	Iron
Boron	Didymium	Lanthanum
Bromine	Erbium	Lead
Cadmium	Fluorine	Lithium
Cæsium	Gallium	Magnesium
Calcium	Germanium	Manganese

Mercury	Rubidium	Terbium
Molybdenum	Ruthenium	Thallium
Nickel	Samarium	Thorium
Niobium	Scandium	Tin
Nitrogen	Selenium	Titanium
Osmium	Silicon	Tungsten
Oxygen	Silver	Uranium
Palladium	Sodium	Vanadium
Phosphorus	Strontium	Ytterbium
Platinum	Sulphur	Yttrium
Potassium	Tantalum	Zinc
Rhodium	Tellurium	Zirconium

To these may perhaps be added a few which are still doubtful, such as norwegium, holmium, thulium, &c., and some which are but dimly recognised as present in the cerite and gadolinite earths. It is also probable that some of those in the list are really not elementary substances, e.g. didymium.

Upon comparison, these elements are found to fall into well-marked natural groups, the members of each group showing close kinship, both as regards themselves and their compounds. At first the classification of the elements was superficial and tentative, being based upon partial resemblances; and even the broad division of them into metals and non-metals was far from being satisfactory. To the earlier chemists nitrogen and bismuth had nothing in common, carbon and tin were totally unlike, while vanadium and chromium were classed together, and so too were tellurium and antimony. But by means of the hypothesis of valency a clearer insight was gained into the true relationships of the elements, and in the announcement of the periodic law (*q. v.*) by Newland, Mendeleeff, and Lothar Meyer, their orderly sequence was at last definitely perceived. To-day all classification of the elements is based primarily upon that law, and illustrates chemical function rather than external properties. The former is fundamental, the latter are but secondary. Furthermore, in consequence of the periodic law all the physical characteristics of the elements are now thought to depend ultimately upon atomic mass, and thus their classification is directly correlated with the atomic theory.

Omitting a very few of the rarer and more imperfectly known elements, the following elementary groups may be distinctly recognised. For the connexion of the several groups with each other the article on the periodic law should be consulted (*cf.* also CLASSIFICATION, p. 203). By suitable divisions the existence of sub-groups is indicated:—

1	2	3	4	5	6	7	8
H	Be	B	C	N	O	F	Fe
—	—	—	Si	P	S	Cl	Ni
Li	Ca	Al	Ti	V	Se	Br	Co
Na	Sr	Ga	Ge	As	Te	I	—
K	Ba	In	Zr	Sb	—	—	Cu

In each of these groups, or, more precisely, in each of the sub-groups, if the elements are arranged in the order of their atomic weights, there is a regular gradation of properties from the lowest to the highest. Among their compounds precisely similar regularities appear, and exceptions are quite uncommon. If one element in a group forms certain well-defined compounds, we may fairly expect them to be paralleled by every other element in the same series, and their points of dissimilarity will follow a regular serial order. Throughout each group, with a few exceptions, there seems to be one dominant valency representing the maximum stability among the derivatives of the members of the group, and these derivatives are frequently isomorphous. Indeed isomorphism between analogously constituted compounds is good evidence of chemical kinship, although it is not proof positive.

As regards abundance, association in nature, and modes of occurrence, the elements differ widely. Including the atmosphere and the ocean, the mass of the earth's crust is mainly made up of thirteen of them, namely, oxygen, hydrogen, nitrogen, carbon, chlorine, sulphur, aluminium, calcium, magnesium, iron, potassium, sodium, and silicon. Certain others, such as fluorine, manganese, lead, and phosphorus, are relatively common, and others, like gallium, indium, and germanium, are exceedingly rare. Comparatively few of the elements are found free in nature, and these are oxygen, hydrogen, nitrogen, carbon, sulphur, tellurium, arsenic, antimony, bismuth, copper, silver, gold, mercury, zinc, tin, lead, iron, and the six platinum metals. Of these only nitrogen, gold, and the platinum group appear to be more abundant free than in a state of union. Compounds are the rule, native elements the exception. In general terms, like elements occur under like conditions, and often in association with each other. Thus cobalt and nickel are seldom found entirely apart, the rarer earths are almost always commingled, and the platinum metals always occur more or less together. Apart from the commoner rock-forming elements, the so-called 'heavy metals' are chiefly found segregated in veins which are produced by infiltration; while the cerium and yttrium groups, beryllium, zirconium, thorium, &c., exist almost solely in granitic intrusions. In sedimentary or detrital rocks the rarer elements which perhaps were present in the parent formations are so widely scattered as to be no longer discernible. The older rock masses yield by far the larger proportion of the known elements. Even in volcanic outflows the number of elements present seems to be relatively small, perhaps because no segregating influence has rendered the presence of the scarcer substances distinctly manifest. In organic matter the elements carbon, hydrogen, oxygen, nitrogen, sulphur, and phosphorus are the dominating constituents.

In the beginnings of chemistry the fact that one substance could be transformed into other substances gave rise to all manner of alchemical speculations. Transmutations of matter gave the young science its only *raison d'être*, and no good reason existed for assigning any limit to such transmutability. The labours of the alchemists, therefore, were not at all unphilosophical, but on the contrary they represented efforts at

generalisation which were perfectly legitimate in their day. But as the modern conception of an element developed, limitations not previously recognised became evident, and the pendulum of chemical opinion swung over towards a belief in the absolute independence and individual integrity of the elementary bodies. From this point of view all theorising as to the nature of the elements became unprofitable, and, indeed, was put outside the proper range of scientific investigation.

Of late years, however, the question has been reopened, the ultimate character of the elements is no longer positively assumed, and the belief is gaining ground that they have been derived from still simpler forms, possibly one form, of matter by some process of evolution. It will be observed that the only evidence in favour of their elementary nature lies in our present inability to decompose them, and that evidence is purely negative. It signifies merely a limitation in our immediate resources; not a limitation essential to the things themselves. On the other hand, the elements are connected by so many intimate relations that their complete independence of each other is hardly supposable. These relations, being definite and surely not accidental, need some hypothesis to explain them, and such an hypothesis, if not fully framed as yet, is at least progressing in its formative stages. The chief lines of discussion now upon are as follows:

First, on the basis of the periodic law (*v. CLASSIFICATION AND PERIODIC LAW*). In his memorable paper upon that subject Mendeleeff arranged the elements in a tabular scheme, in which certain gaps existed. These gaps, he claimed, should be filled by undiscovered elements, for three of which he predicted the properties in considerable detail. Several years later, in 1876, Lecoq de Boisbaudran discovered gallium, and that metal was found to fill one of the gaps perfectly, conforming with curious accuracy to Mendeleeff's predictions. Since then scandium has been discovered by Nilson, and germanium by Winkler, and they with striking definiteness confirm the remainder of the prophecy. In brief, the prediction of these three metals and its subsequent confirmation would not have been possible were the elements entirely distinct and unrelated. Again, if we plot graphically any set of physical properties of the elements, using them for abscissæ and the atomic weights for ordinates, the periodic relations become strikingly manifest. This is seen in the case of Lothar Meyer's curve of atomic volumes, in which similar elements occupy similar places, and by means of which volumes not actually measured can be approximately estimated. Although as yet no such curve has been interpreted mathematically, there is little doubt but that in time the relations which are so expressed will receive accurate formulation.

Secondly, there is spectroscopic evidence in favour of elementary evolution. If we accept the nebular hypothesis as to the origin of the solar system, we must give weight to the varying chemical complexity of the heavenly bodies. First, the nebulae themselves are gaseous, and consist very largely of hydrogen. In the whiter, and presumably hotter, stars a few other substances appear, more are found in the sun, and

finally we have the cooled planet, seemingly the most complex of all. This evidence was first summed up by Clarke in 1878 (*Popular Science Monthly*, January 1878), who drew from it the conclusion that the evolution of planets from nebulae had been accompanied by an evolution of the chemical elements. In November of the same year, in a letter to Dumas, Lockyer put forth a similar conception, resting on the same evidence, and argued that in the hotter stars the elements are dissociated. This hypothesis has since been somewhat amplified by Lockyer in numerous publications, and has attained considerable notoriety. It may be further emphasised by the fact that the thirteen commonest elements are all of relatively low atomic weight, while the higher, denser, and probably more complex metals are, as a rule, scarce. Of course the weight of the latter argument is weakened by our ignorance of the earth's interior, and the fact that the mean density of our planet is much greater than that of its crust. The heavier elements may be relatively more abundant near the centre of the earth, as the lighter ones are at the surface.

Still a third line of argument has been fruitful in speculative literature, namely, the study of relations between the atomic weights. In 1829 Doebereiner showed that certain elements constituted triads, in which the middle term had an atomic weight nearly the mean of the atomic weights of the extremes. Such a triad is formed by calcium, strontium, and barium, by chlorine, bromine, and iodine, and by lithium, sodium, and potassium. In 1851 this matter was discussed independently by Pettenkofer and by Dumas, and since then many other writers have studied it. It is now, of course, supplanted by the more general periodic law; but it led to one conception of curious interest. It was early noticed that each triad had certain resemblances to the series formed by organic radicles, as in the paraffin and olefine groups, and the question was raised whether a real analogy might not exist. Now in any organic series isomerism among the derivatives increases as we ascend, and a similar rule seems to hold in some groups of elements. One example will suffice. The metallic chlorides and bromides rarely, if ever, assume allotropic or isomeric conditions. But among the iodides, allotropy seems to be common; illustrations are furnished by the iodides of antimony, mercury, and cadmium. Each of these salts exists in at least two distinct modifications, while the corresponding chlorides and bromides show no similar variability. In itself this argument carries little weight, but with other evidence it adds to the strength of the modern position.

Passing over all other discussions concerning relations between the atomic weights, we now come to one controversy which still has living interest; the controversy over 'Prout's law.' In 1815 Prout suggested that hydrogen, the lightest of the elements, might be the one primal form of matter, and claimed that the atomic weights of all the other elements were whole multiples of that of hydrogen. This hypothesis as to the atomic weights broke down in its original form, but in 1859 Dumas endeavoured to show that it held as regards half and even quarter multiples. Then came Stas, with his

marvellous determinations of many equivalent ratios, which seemingly proved the absolute untenability of Prout's law, even with Dumas' modifications. In consequence of Stas' researches, Prout's law has been of late years out of favour among chemists, and it has generally been assumed that the question was settled adversely. But in 1880 Mallet published his paper upon the atomic weight of aluminium (*T.* 1880. 1003). In this paper he cites the atomic weights of eighteen elements which he regards as fairly well determined, and shows that ten of them have values varying less than 0.1 from even multiples of unity. This concordance may be accidental; but under the theory of probabilities the chances are 1097.8 to 1 against mere coincidence. Two years later, Clarke, in his 'Recalculation of the Atomic Weights,' extended Mallet's argument to sixty-six elements, of which forty had atomic weights, as then determined, falling within the limit of 0.1 variation from theory.<sup>1</sup> The forty agreements include nearly all the trustworthy determinations, while the twenty-six exceptions are mostly among elements of which the atomic weights had been defectively ascertained. This evidence strengthens materially the argument used by Mallet. It must be remembered that the methods ordinarily employed for computing atomic weights tend to develop apparent variations, through the multiplication of seemingly insignificant errors. The conclusion to be drawn from the whole discussion is, that some law like Prout's, if not identical with Prout's, actually exists; for so large a proportion of close coincidences could hardly be due to mere chance. In this connexion the observation of Meyer and Seubert (*C. J.* 47, 480), that about one-fourth of the elements have atomic weights approximating nearly to even multiples of one-half the atomic weight of oxygen, is surely worth noting. Recently there have been several attempts to bring the atomic weights under one general mathematical law, but the work so far done is hardly complete enough to warrant farther notice. The most promising effort is probably that of G. Johnstone Stoney (*Pr.* 44, 115). The whole question, however, is conditioned by discussions upon the possible variability of the atomic weights and the constancy of chemical composition, such as have been raised by Schützenberger (*B.* 39, 258), Butlerow (*ibid.* p. 263), and Cooke (*Am.* [3] 26, 310). Little weight is at present attached to that class of speculations, although the arguments which they involve cannot wholly be ignored.

To a certain extent the nature of the elements is considered by Sir Benjamin Brodie in his 'Ideal Chemistry' and his 'Calculus of Chemical Operations;' but along lines of reasoning which cannot well be entered upon here. Very recently also the subject has been extensively treated by Crookes, and from a novel point of view. He has studied the phosphorescent spectra of the rare earths; and has found that by working with products which represent hundreds of fractional precipitations, he can get strikingly different spectra for what is to all chemical tests one and the same oxide. Thus yttria, after many

<sup>1</sup> When 0 = 16 as the base of the system.

fractionations, divides into products which are unlikespectroscopically; just as if the molecules of the original earth had either been sorted out from a mixture, or else split up into new groups. These products, differing from ordinary yttria, are the oxides of what Crookes provisionally calls 'meta-elements.' In the same category, perhaps, we must place the neodymium and praseodymium of Auer von Welsbach, derived from didymium; and also the many doubtful earths obtained from samarskite, gadolinite, &c., by Marignac, De Boisbaudran, and Krüss and Nilson. Unfortunately we do not yet know how to interpret all the phenomena, and the evidence admits of various explanations. We may have merely allotropes to deal with, or there may have been a veritable splitting up of relatively unstable elements. That the actual number of distinct earthy oxides should be very largely increased is unlikely, for they fit no vacant places in the periodic system. Crookes himself interprets the evidence thus:—Following along the line of elementary evolution, he conceives that matter, as it developed from the original 'protyle,' passed from stable point to stable point through intervals of instability. Around each accretion of the primitive stuff into a definite element there may be gathered a few particles of intermediate material; and these 'by-products' of elementary manufacture, separable only by long fractionations, may give rise to the phenomena observed in the spectra of yttria. The main line of evolution he represents by a lemniscate curve.

This work of Crookes, as represented in his address of 1886 before the British Association, and in two later lectures before the Chemical Society (*C. J.* 53, 487), brings us face to face with the final question of all. Admitting that the elements have been somehow evolved from simpler primal forms, can the process ever be repeated or reversed artificially? To this question no answer is now possible; but it seems likely that if a transmutation of so-called elementary matter should ever be effected in the laboratory, it will be by the very slow development, under conditions of prolonged chemical stress, of change in traces only.

F. W. C.

**ELEMI.** A name given to various resins. *Elemi occidentale* is said to be the produce of *Icica Icicariba*; *Elemi orientale* to come from *Amyris ceylonica*. *Elemi aegyptiacum* is perhaps produced by *Elaeagnus hortensis*. Translucent resins, used in making varnishes. Some specimens contain amyryl (*q. v.*) and elemi. Elemi forms thin six-sided prisms [200°] (Johnston, *A.* 44, 338; Rose, *A.* 32, 297; 40, 307; Hess, *A.* 29, 139; Baup, *J. Ph.* [3] 20, 321; Buri, *N. Rep. Pharm.* 25, 193). Arbol-a-brea resin contains bryoidin  $C_{10}H_{16}O$ , [136°] (Flückiger, *J.* 1875, 860). According to Stenhouse and Groves (*A.* 180, 253) incense-resin (from *Icica heptaphylla*) contains conimene  $C_8H_8$ , and icacin  $C_{10}H_{16}O$ . When elemi resin derived from *Amyris elemifera* and *A. ceylonica* is distilled with zinc-dust it yields toluene, *m*- and *p*-ethyl-toluene, and ethyl-naphthalene (Ciamician, *G.* 9, 310; *B.* 11, 1344).

Oil of elemi  $C_{15}H_{16}$ , (166°) (Stenhouse, *A.* 85, 804); (174°) (Deville, *A.* 71, 352). S.G.

24.852. V.D. 4.0. [ $\alpha_D$ ] = -90°. Oil, obtained by distilling elemi with steam. HCl forms solid inactive  $C_{15}H_{16}Cl$  and a liquid isomeride.

**ELEMIC ACID**  $C_8H_8O_4$ , [215°].  $\alpha_D$  = -3.5°. Occurs in elemi, and purified by means of the K salt (Buri, *Ph.* [3] 8, 601).

**Properties.**—Large crystals (from alcohol). Insol. water, sol. alcohol and ether, sl. sol.  $CS_2$ . Its alcoholic solution reddens litmus.

**Salt.**— $KA^{18}aq$ : needles.

**ELLAGIC ACID**  $C_6H_6O_4$ , *i.e.*

(Schiff, *B.* 12, 1533). S.G. 1.667. A constituent of Oriental bezoars (Chevreul, *A. Ch.* [2] 9, 629; Braconnot, *A. Ch.* [2] 9, 187; Pelouze, *A. Ch.* [2] 54, 367; Taylor, *P. M.* [3] 24, 354; Wöhler a. Merklein, *A.* 55, 129). Occurs also in sprouts of the divi-divi (Löwe, *Fr.* 14, 40; Barth a. Goldschmidt, *B.* 11, 846; 12, 1233; Cobenzl, *M.* 1, 671) and in oak bark (Etti, *M.* 1, 266) and fir bark (Strohmmer, *M.* 2, 539).

**Formation.**—1. From gallic acid or tannin, by treatment with iodine,  $POCl_3$ ,  $PCl_5$ , or  $As_2O_3$  (Griessmayer, *A.* 160, 55; Löwe, *Z.* 1868, 603). It is also deposited as a grey powder when a decoction of gallnuts is left exposed to the air.—2. By heating gallic ether with aqueous NaOH at 60° (Schiff, *B.* 12, 1533).

**Preparation.**—Bezoars are dissolved in strong aqueous KOH in the cold;  $CO_2$  is then passed in, when potassium ellaglate is ppd. This is recrystallised from water, and the acid is liberated by hydrochloric acid.

**Properties.**—Minute yellowish prisms (containing 2aq). Insol. water and ether, sl. sol. alcohol. A solution in conc. KOHAq when exposed to the air deposits black crystals of 'potassium glaucomelanate'  $C_{12}H_8K_2O_4$  (?), which is reconverted into ellaglate by boiling water. Conc.  $H_2SO_4$  dissolves ellagic acid without change.  $FeCl_3$  gives a greenish colour becoming black.

**Reactions.**—1. Distillation with zinc-dust gives fluorene  $C_{10}H_{10}$ .—2. Sodium amalgam in alkaline solution gives 'glauc-hydro-ellagic acid'  $C_{12}H_{10}O_4$ , 'rufo-hydro-ellagic acid'  $C_{12}H_{10}O_4$  (Riembold, *B.* 8, 1494; Cobenzl, *M.* 1, 671), an acid  $C_{12}H_{10}O_4$ , and finally ( $\gamma$ )-hexa-oxy-diphenyl. 3. Potash-fusion gives ( $\beta$ )-hexa-oxy-diphenyl (*B. a. G.*).—4. Boiling conc. KOHAq gives hexa-oxy-diphenylene ketone.

**Salts.**— $KA^{18}$  (at 150°): minute prisms.— $KA^{18}KOH$  (?): grey powder.— $Na_2A^{18}aq$ : pale yellow crystalline powder, sl. sol. water.— $NaHA^{18}aq$  (at 100°).— $Ba_2A^{18}aq$  (at 140°): lemon-yellow insoluble pp.— $PbA^{18}aq$ : amorphous yellow pp.; becomes olive-green on drying.

**Tetra-acetyl derivative**  $C_{12}H_4Ac_4O_8$ . Yellow crystalline powder, sl. sol. water.

**ELLAGITANNIC ACID**  $C_{12}H_{10}O_{10}$ . Occurs in divi-divi and myrobalanes (Löwe, *Fr.* 14, 44). Amorphous brownish mass. Water at 110° converts it into ellagic acid.— $(C_{12}H_{10}O_{10})_2 \cdot 5PbO$ .

**ELUTRIATION.** The separation of lighter from heavier particles by washing.

**EMETINE**  $C_{14}H_{18}N_2O_2$  (?). [65°-74°]. S. 1 in the cold. Occurs in ipecacuanha root (Pelletier a. Magendie, *A. Ch.* [2] 4, 172; Buchner, *Repert. Pharm.* 7, 289; Dumas a. Pelletier, *A.*

Oh. [2] 24, 180; Lefort, *J. Ph.* [4] 9, 241; Pander, *C. C.* 1872, 440; Glenard, *C. R.* 81, 100; Lefort a. F. Wurtz, *C. R.* 84, 1299; Power, *Ph.* [3] 8, 344; Kunz, *Ar. Ph.* [3] 25, 461; Podwysotsky, *Ph.* [3] 10, 642; Kremel, *Ar. Ph.* [3] 26, 419.

**Preparation.**—Ipecacuanha is exhausted with ether and ligroin and the residue extracted with (85 p.c.) alcohol; the extract is evaporated to a syrup, and  $\text{FeCl}_3$  added to ppt. tannin; excess of  $\text{Na}_2\text{CO}_3$  is added, and the emetic extracted with hot ligroin.

**Properties.**—Needles (from ligroin). Sl. sol. water, v. sol. chloroform,  $\text{EtOAc}$ , alcohol,  $\text{CS}_2$ , and essential oils, sl. sol. ligroin, ether, and benzene. Alkaline reaction. Coloured yellow by sunlight. Produces vomiting. Except the tannate, all its salts are amorphous. Sulphomolybdic acid gives a brown colour, changed by  $\text{HCl}$  to indigo blue. Potassium-bismuth iodide gives a pp., as do other re-agents for alkaloids.

**Salts.**— $\text{B}^+\text{H}^-\text{PtCl}_6$ : yellowish-white powder. — $\text{B}^+\text{H}^-\text{CrO}_4$ . — $\text{B}^+\text{Me}^-\text{Cl}$ . — $\text{B}^+\text{Me}^-\text{OH}$ .

**EMODIN** v. Tri-oxymethyl-anthraquinone. **EMULSIN**. A neutral substance contained in sweet and in bitter almonds, and possessing the power of acting as a ferment on the amygdalin of the latter in presence of water, converting it into benzoic aldehyde,  $\text{HCy}$ , and glucose (Robiquet, *J. Ph.* 24, 326; Thomson a. Richardson, *A.* 20, 180; Orloff, *Ar. Ph.* 48, 16; Bull, *A.* 69, 145; Johannsen, *Bied. Cent.* 1888, 326). It may be obtained by leaving an aqueous extract of almond cake at  $23^\circ$  for a few days, filtering, and ppg. with alcohol. White amorphous mass, sol. water. The hydrolytic power of emulsin is destroyed by boiling.

**ENCEPHALIN** v. CEREBRIN.

**n-ENNANE**  $\text{C}_9\text{H}_{20}$ . *Nonane*. Mol. w. 128. [ $-51^\circ$ ]. (150°). S.G.  $\frac{2}{4}$  733;  $\frac{12}{4}$  6541. From pelargonic acid  $\text{C}_9\text{H}_{19}\text{O}_2$  by distillation with P and HI (Krafft, *B.* 15, 1692).

**Ennane**  $\text{C}_9\text{H}_{20}$ . (148°). S.G.  $\frac{21}{4}$  7124. V.D. 65.4 (for 64). Occurs in Galician petroleum (Lachowicz, *A.* 220, 194).

**Ennane**  $\text{C}_9\text{H}_{20}$ . (136°). S.G.  $\frac{12}{4}$  742. V.D. 4.59 at  $180^\circ$ . Occurs in petroleum (Lemoine, *Bl.* [2] 41, 163).

**Ennane**  $\text{C}_9\text{H}_{20}$ . (130°). S.G.  $\frac{2}{4}$  743. V.D. 4.47 at  $190^\circ$ . Occurs in petroleum (L.).

**Ennane**  $\text{C}_9\text{H}_{20}$  i.e.  $\text{Pr}.\text{CH}_2.\text{CH}_2.\text{CH}_2.\text{Pr}$ . (132°). S.G.  $\frac{2}{4}$  725. From isoamyl iodide, isobutyl iodide and Na (Wurtz, *A. Ch.* [3] 44, 276).

**Ennane**  $\text{C}_9\text{H}_{20}$ . (130°). From isopropyl iodide and Na (Silva, *B.* 5, 984).

**ENNDICANE**  $\text{C}_{10}\text{H}_{22}$  i.e.  $\text{CH}_3(\text{CH}_2)_8\text{CH}_3$ . *Nonadecane*. [32°]. S.G.  $\frac{22}{4}$  7774;  $\frac{22}{4}$  7328. From  $\text{C}_{10}\text{H}_{21}\text{Cl}$  by heating with HI and phosphorus. Occurs also in paraffin from bituminous shale (Krafft, *B.* 15, 1704; 21, 2256).

**ENNDICANE DI-CARBOXYLIC ACID**  $\text{C}_{10}\text{H}_{18}(\text{CO}_2\text{H})_2$ . [90°]. From oxy-hemicosic acid  $\text{C}_{10}\text{H}_{19}(\text{CH}_2\text{OH})(\text{CO}_2\text{H})$  by heating with soda-lime (Stärcke, *A.* 223, 812). White powder (from alcohol and light petroleum).

**Salt.**— $\text{PbA}^+$ .

**ENNOIC ACID**  $\text{C}_9\text{H}_{16}\text{O}_4$  i.e.  $\text{CPr}_2.\text{CH}.\text{CO}_2\text{H}$ . *Di- $\beta$ -propyl-acrylic acid*. [81°]. From  $\text{Pr}.\text{C}(\text{OH})(\text{CH}_2\text{CO}_2\text{H})$  and dilute  $\text{H}_2\text{SO}_4$  (Albitzky, *J. pr.* [2] 30, 209). Needles (from benzene). Sl. sol. water, v. sol. alcohol, ether, and benzene. —

$\text{LiA}^+ 2\text{aq.} - \text{BaA}^+, \text{aq.} - \text{CaA}^+, \text{aq.}$  S. (of  $\text{CaA}^+$ ) 3.3 at  $21^\circ$ . — $\text{PbA}^+$ , 2.2aq.

**Ennoic acid**  $\text{C}_9\text{H}_{16}\text{O}_4$  i.e.  $\text{C}_6\text{H}_5.\text{CH}.\text{CH}.\text{CO}_2\text{H}$ . *Nonyleneic acid*. Formed by heating heptioic aldehyde (ananthol) with  $\text{NaOAc}$  and  $\text{Ac}_2\text{O}$  at  $170^\circ$  for 30 hours (Schneegans, *A.* 227, 80). Liquid, v. sl. sol. water, very volatile with steam. Readily combines with  $\text{HBr}$  forming bromo-ennoic acid (*q. v.*). Not attacked by nascent hydrogen. — $\text{BaA}^+$ . — $\text{CaA}^+$ , 3aq; needles. — $\text{AgA}^+$ .

**Ennoic acid**  $\text{C}_9\text{H}_{16}\text{O}_4$ . *Phoronic acid*. [169°]. [ $\alpha_D$ ] =  $-23^\circ$  (in alcohol). Formed, together with camphic acid, by exposing sodium-camphor to the air (Montgolfier, *A. Ch.* [5] 14, 82). Tables (from alcohol). Insol. water and  $\text{CS}_2$ .

**ENNENYL ALCOHOL**  $\text{C}_9\text{H}_{18}\text{O}$  i.e.  $\text{Pr}.\text{CH}:\text{CH}.\text{CH}_2.\text{CM}_2.\text{OH}$ . *Di-methyl-isopropyl-allyl-carbinol*. (176°).  $R_{\infty} = 72.27$ . From dimethyl-allyl-carbinol (hexenyl alcohol), isopropyl iodide, and zinc (Dieff, *J. pr.* [2] 27, 364). Gives isobutyric acid on oxidation. Combines with bromine forming  $\text{C}_9\text{H}_{17}\text{BrO}$ .

**Methyl ether**  $\text{C}_9\text{H}_{18}\text{OMe}$ . (171°). S.G.  $\frac{21}{4}$  8027.  $R_{\infty} 81.55$ .  $\text{KMnO}_4$  gives methylated oxy-valeric acid,  $\text{CH}_3\text{O}.\text{C}_4\text{H}_7\text{CO}_2\text{H}$ , and isobutyric acid (Kononowitz, *J. pr.* [2] 30, 400; *Bl.* [2] 43, 381).

**ENNENYLCHLORIDE**  $\text{C}_9\text{H}_{17}\text{Cl}$ . (175°–185°). From the alcohol and  $\text{PCl}_5$  (Dieff).

**ENNINENE**  $\text{C}_9\text{H}_{18}$ . (136°). *Campholene*. Obtained from campholic acid by the action of  $\text{P}_2\text{O}_5$  or by distilling with soda-lime (Delalande, *A.* 38, 340; Kachler, *A.* 162, 266).

**Enninene**  $\text{C}_9\text{H}_{18}$ . (135°–140°). From camphor and HI at  $200^\circ$  (Weyl, *B.* 1, 96).

**ENNINYL ALCOHOL**  $\text{C}_9\text{H}_{18}\text{O}$  i.e.  $(\text{CH}_3:\text{CH}.\text{CH}_2)_2.\text{CET}.\text{OH}$ . *Ethyl-di-allyl-carbinol*. (176°). S.G.  $\frac{2}{4}$  8716;  $\frac{12}{4}$  8637. C.E. ( $0^\circ$ – $17^\circ$ ) 00095. From propionic ether, allyl iodide, and zinc (Smirensky, *J. pr.* [2] 25, 59).

**n-ENNOIC ACID**  $\text{C}_9\text{H}_{16}\text{O}_4$ . *Pelargonic acid*. *Nonylic acid*. Mol. w. 168. [13°]. (254° i.V.). S.G.  $\frac{12}{4}$  9109;  $\frac{12}{4}$  9103;  $\frac{22}{4}$  8433. H.C. 1287352. M.M. 9.590 at  $20^\circ$  (Perkin, *C. J.* 45, 486; Longuine, *A. Ch.* [6] 11, 222).

**Occurrence.**—In the volatile oil of *Pelargonium roseum* (Pless, *A.* 59, 54). In fusel oil from beet root (Perrot, *A.* 105, 64).

**Formation.**—1. From heptyl-aceto-acetic ether and  $\text{KOH}$  (Jourdan, *A.* 200, 105).—2. By action of  $\text{HNO}_3$  on oleic acid (Redtenbacher, *A.* 59, 52), on stearolic acid (Limpach, *A.* 190, 297), and on oil of rue (Gerhardt, *A.* 67, 245).—3. By heating hendecenoic acid  $\text{C}_{11}\text{H}_{20}\text{O}_2$  with  $\text{KOH}$  (Krafft, *B.* 15, 1691).

**Properties.**—Oil at ordinary temperatures. **Salts.**— $\text{CaA}^+$ . — $\text{BaA}^+$ : laminae, sl. sol. hot water. — $\text{CuA}^+$ , [c.  $258^\circ$ ]. — $\text{ZnA}^+$ , [132°]. — $\text{AgA}^+$ .

**Methyl ether**  $\text{MeA}^+$ . (214° i.V.). S.G.  $\frac{22}{4}$  8918. S.V. 245.7. C.E. ( $0^\circ$ – $10^\circ$ ) 00091 (Gartenmeister).

**Ethyl ether**  $\text{EtA}^+$ . (228° i.V.). S.G.  $\frac{12}{4}$  8655 (Zincke a. Franchimont, *A.* 164, 339;  $\frac{12}{4}$  8703;  $\frac{22}{4}$  8641. M.M. 11.571 at  $18.2^\circ$  (Perkin, *C. J.* 45, 503).

**Chloride**  $\text{C}_9\text{H}_{17}\text{OCl}$ . (220°) (Cahours, *C. J.* 3, 240).

**Amide**  $\text{C}_9\text{H}_{17}\text{ONH}_2$ . [93°] (Schaltejeff, *B.* 6, 1252); [90°] (Hofmann, *B.* 15, 984). Formed

- by heating ammonium ennoate at 230° under pressure.
- Anhydride**  $C_6H_8O_4$ . [-5°] (Chiozza, *A.* 85, 231).
- Nitrile**  $CH_3(CH_2)_4CN$ . (215°). S.G. 1.2786. From *n*-octyl iodide and KCN at 180° (Eichler, *B.* 12, 1888).
- Iso-ennoic acid**  $C_6H_{10}O_4$ , i.e.  $CH_3(CH_2)_4CHMe.CO_2H$ . (245° cor.). S.G. 1.9033. From its nitrile, which is obtained by acting on methyl-hexyl-carbonyl iodide (octyl iodide) with KCy (Kullhem, *A.* 173, 319). Oil.—NaAq: slender needles.—KA':—CaA': aq: needles (from alcohol).—CuA': aq.—AgA'.
- Ethyl ether EtA'**. (214° cor.). S.G. 1.8641.
- Nitrile**  $CH_3(CH_2)_4CHMe.CN$ . (206°). S.G. 1.8187.
- Amide**  $CH_3(CH_2)_4CHMe.CONH_2$ . [91°] and [105°] (?).
- Ennoic acid**  $CH_3(CH_2)_4CHMe.CH_2.CO_2H$ . (232°). Got by heating heptyl-malonic acid (Venable, *B.* 13, 1652). Oil.
- V. also Bromo-ENNOIC ACID.**
- ENNYL ALCOHOL**  $C_6H_{12}O$ . *Nonyl alcohol*. Mol. w. 144. (c. 188°). S.G. 1.25-855. From petroleum enane (Lemoine, *Bl.* [2] 41, 163; cf. Pelouze & Cahours, *A. Ch.* [4] 1, 5).
- Acetyl derivative**  $C_6H_{12}OAc$ . (c. 210°).
- Ennyl alcohol**  $C_6H_{12}O$ . (205°-212°). S.G. 1.847. From isomyl isovalerate and sodium (Lourenço & Aguiar, *Z.* 1870, 404).
- Acetyl derivative**  $C_6H_{12}OAc$ . (207°-213°).
- Ennyl alcohol**  $Pr_3CEt.OH$ . *Ethyl-di-propyl-carbinol* (Tschebotareff & Saytzeff, *J. pr.* [2] 33, 195). (179°-5° cor.) (T. a. S.); (176°) (Menschikoff, *J. pr.* [2] 36, 351). V.D. 143.5 (for 144). V. sl. sol. water. S.G. 0.8331; 0.8258. From di-propyl ketone, EtI, and Zn. Gives, on oxidation,  $CO_2$ , acetic acid, propionic acid, and butyric acid, also di-propyl ketone and ennylene.
- Acetyl derivative**. (c. 190°). S.G. 0.8675.
- Ennyl alcohol**  $C_6H_{12}O$ . *CHCl.OH*. (195°). S.G. 0.839; 0.825. From heptoic aldehyde (enanthal) and  $ZnEt_2$ , followed by water (Wagner, *Bl.* [2] 42, 830). Gives ethyl hexyl ketone on oxidation.
- Acetyl derivative**  $C_6H_{12}OAc$ . (211°). S.G. 0.878; 0.861.
- ENNYLAMINE**  $C_6H_{12}NH_2$ . (191°). Formed by the action of  $NH_3$  on the ennyl chloride derived from petroleum (Pelouze & Cahours, *J.* 1863, 529; *A. Ch.* [4] 1, 5).
- Ennylamine**  $C_6H_{12}NH_2$ . (195°). Formed by the action of Br and KOH on the amide of decioic (capric) acid (Hofmann, *B.* 15, 773).— $B'H_4PtCl_6$ .
- ENNYL CHLORIDE**  $C_6H_{12}Cl$ . (c. 182°) (Lemoine, *Bl.* [2] 41, 164; (196°) (Pelouze & Cahours, *J.* 1863, 529). S.G. 1.899 (P. a. C.); 1.908 (L.). From petroleum enane by chlorination.
- Ennyl chloride**  $C_6H_{12}Cl$ . (150°-160°). From the ennyl alcohol obtained from isomyl isovalerate and Na (Lourenço & Aguiar, *Z.* 1870, 404).
- ENNYLENE**  $C_6H_{10}$ . *Nonylene*. Mol. w. 126. (c. 185°). S.G. 1.851-853. From the ennyl chloride which is derived from petroleum (Lemoine, *Bl.* [2] 41, 163).
- Ennylene**  $C_6H_{10}$ . (138°). S.G. 1.743. From ethyl-di-propyl-carbonyl iodide and alcoholic KOH (Socloff, *J. R.* 1887, 599).
- Ennylene**  $C_6H_{10}$ . (140°). Among the products of the action of  $ZnCl_2$  on fusel oil (Wurtz, *A.* 128, 232).
- Ennylene**  $C_6H_{10}$ . (145°). S.G. 1.757. Formed by the action of lime on heptoic aldehyde (enanthal) (Fittig, *A.* 117, 78).
- Ennylene**  $C_6H_{10}$ . (c. 147°). From paraffin, by strongly heating it (Thorpe & Young, *A.* 165, 18).
- Ennylene**  $C_6H_{10}$ . (c. 149°). S.G. 1.787. Occurs in oil of resin (Renard, *Bl.* [2] 39, 541).
- Ennylene**  $C_6H_{10}$ . (153° cor.). S.G. 1.762. Obtained by distilling the lime soap made from train oil (Warren & Storor, *Z.* 1868, 230).
- Ennylene**  $C_6H_{10}$ . (121°). S.G. 1.753. Found among the products of the distillation of bituminous shale (Laurent, *A.* 25, 285).
- V. also the Hexahydrides of CUMENE and MESITYLENE.**
- DI-ENNYL-KETONE**  $C_{12}H_{20}O$  i.e.  $(C_6H_{10})_2CO$ . *Caprinone* [58°]. (above 350°). Obtained by distilling calcium decanoate (caprate). Pearly laminae (from alcohol). Gives decioic acid on oxidation (Grimm, *A.* 157, 270).
- ENNYL-UREA**. *Decoyl derivative*  $C_6H_{12}NH.CO.NH.CO.C_6H_{12}$ . [101°]. White plates. Formed by the action of KOH on a mixture of the amide of decioic acid and bromine (Hofmann, *B.* 15, 761).
- EOSIN v. Tetra-BROMO-FLUORESCIN.**
- EPIBROMHYDRIN**  $C_6H_8BrO$ . (189°). S.G. 1.615. From  $C_6H_8Br_2$  (Oll), and conc. KOHAq (Reboul, *A. Suppl.* 1, 227; Berthelot & De Luca, *A. Ch.* [3] 48, 311). Formed also by distilling the compound of acetone with Br (Linnemann, *A.* 125, 310).  $NH_3$  forms  $C_6H_8BrNO_2$ , an amorphous insoluble base.
- Epidibromhydrin v. DI-BROMO-PROPYLENE.**
- EPICHLORHYDRIN**  $C_6H_8ClO$  i.e.,
- O  
|  
 $CH_2Cl.CHCl_2$
- Chloro-propylene oxide*. Mol. w. 92. (115-9°) (Schiff, *A.* 220, 99); (116.6 cor.) (Thorpe, *C. J.* 37, 207). S.G. 1.2031. C.E. (0°-10°) 0.01033; (0°-100°) 0.011551. V.D. 3.21 (for 3.19). S.V. 87.1 (S.); 87.3 (T.).
- Formation**.—1. By treating di-chloro-propyl alcohol (glycerin dichlorhydrin) with fuming or gaseous HCl (Berthelot, *A. Ch.* [3] 41, 299). 2. By the action of alkalis on either of the two di-chloro-propyl alcohols  $CH_2Cl.CHCl_2.OH$  or  $CH_3Cl.CH(OH).CH_2Cl$  (Reboul, *A. Suppl.* 1, 221; Tollens & Munder, *Z.* 1871, 252; Prevost, *J. pr.* [2] 12, 160; Claus, *B.* 10, 557; Cloëz, *A. Ch.* [6] 9, 145).
- Properties**.—Liquid with sweet taste, smelling like chloroform. Nearly insol. water, mixes with alcohol and ether.
- Reactions**.—1. *Water* ( $\frac{1}{3}$  vol.) at 100° converts it into chlorhydrin  $CH_2Cl.CH(OH).CH_2(OH)$  and glycerin.—2. *Fuming HCl* readily acts upon it, forming  $CH_2Cl.CH(OH).CH_2Cl$  (180°).—3. *HBr* forms  $CH_2Cl.CH(OH).CH_2Br$  (197°). S.G. 1.740. 4. *HI* acts with great violence, forming  $CH_2Cl.CH(OH).CHI$  as well as propyl iodide and *n*-propyl chloride (Silva, *C. R.* 93, 418).—5.  $PCl_5$  forms  $CH_2Cl.CHCl_2.CH_2Cl$ .  $PCl_3$  forms  $C_6H_8Cl_4(OPCl_2)_2$  (c. 186°) at 100 mm. (Hanriot, *Bl.*

[2] 32, 551].—6. *Phosphorus pentabromide* gives  $\text{CH}_3\text{Cl}.\text{CHBr}.\text{CH}_2\text{Br}$  (Darmstädter, A. 152, 819; cf. Wichelhaus, A. Suppl. 6, 277).—7. *Bromine* at  $100^\circ$  forms chloro-tri-bromo-acetone (Grimaux & Adam, Bl. [2] 83, 257).—8. A solution of  $\text{HClO}$  (7 p.c.) in water in darkness produces  $\text{C}_2\text{H}_5\text{Cl}_2\text{O}$ , or  $\text{C}_2\text{H}_5\text{Cl}_2(\text{OH})_2$  (Carius, A. 184, 71).—9. *Acetyl chloride* in the cold, or more quickly at  $100^\circ$ , forms  $\text{C}_2\text{H}_5\text{Cl}_2(\text{OAc})$ . By long heating (50 hours) at  $100^\circ$  there is also formed  $\text{C}_2\text{H}_5\text{Cl}_2\text{O}(\text{OAc})$  and  $\text{C}_2\text{H}_5\text{Cl}_2\text{O}_2(\text{OAc})$ . *Butyryl chloride* forms  $\text{C}_4\text{H}_9\text{Cl}_2(\text{O.CO.Pr})$ . *Benzoyl chloride* at  $180^\circ$  gives  $\text{C}_6\text{H}_5\text{Cl}_2(\text{OBz})$  (Truchot, Bl. [2] 5, 447; 6, 481).—10. *Acetic anhydride* at  $180^\circ$  gives  $\text{C}_2\text{H}_5\text{Cl}(\text{OAc})_2$  and  $\text{C}_2\text{H}_5\text{Cl}_2(\text{OAc})$  (T.; cf. Franchimont, R. T. C. 1, 43). Heating with *acetic acid* at  $100^\circ$  forms  $\text{C}_2\text{H}_5\text{Cl}(\text{OH})(\text{OAc})$ . *Benzoic anhydride* at  $190^\circ$  gives  $\text{C}_6\text{H}_5(\text{OBz})_2$  [74°] (Van Romburgh, R. T. C. 1, 46).—11. Conc.  $\text{K}_2\text{SO}_4$  aq forms  $\text{C}_2\text{H}_5(\text{OH})(\text{SO}_3\text{K})_2$  2aq and free  $\text{KOH}$  (Pazschke, Z. [2] 5, 512).—12.  $\text{NaHSO}_4$  at  $100^\circ$  forms  $\text{CH}_3\text{Cl}.\text{CH}(\text{SO}_3\text{Na})\text{CH}_2\text{OH}$  (Darmstädter, Z. [2] 4, 342).—13. *Alcohol* at  $180^\circ$  gives rise to  $\text{C}_2\text{H}_5\text{Cl}_2(\text{OH})$ ,  $\text{C}_2\text{H}_5(\text{OH})(\text{OEt})_2$ , and  $\text{C}_2\text{H}_5\text{Cl}(\text{OH})(\text{OEt})$ . *Isomyl alcohol* at  $220^\circ$  forms  $\text{C}_5\text{H}_{11}\text{Cl}(\text{OH})(\text{OC}_2\text{H}_5)_2$ ,  $\text{C}_5\text{H}_{11}\text{Cl}_2(\text{OH})$ , and  $\text{C}_5\text{H}_{11}(\text{OH})(\text{OC}_2\text{H}_5)_2$ .—14. *Ethyl bromide* gives  $\text{C}_2\text{H}_5\text{ClBr}(\text{OEt})$ .—15. *Sodium* forms a yellow oil  $\text{C}_2\text{H}_5\text{O}_2$  (c.  $218^\circ$ ), and an insoluble compound  $\text{C}_2\text{H}_5\text{O}_2\text{Na}_2\text{Cl}_2$  (Hübner & Müller, A. 159, 186; Hanriot, Bl. [2] 32, 552; Claus, B. 10, 556).—16. *Sodium ethylate* free from alcohol forms  $\text{C}_2\text{H}_5(\text{OH})(\text{OEt})$ , and white hygroscopic  $\text{C}_2\text{H}_5\text{O}_2$  (Lauter, Jena. Zeit. [2] iii. 2 Suppl. 141; cf. Lourenco, A. Ch. [3] 67, 309).—17. *Alcoholic KOH* forms crystalline  $\text{C}_2\text{H}_5\text{O}(\text{OPh})$  (Lippmann, Sitz. W. 62 [2] 605).—18. *Sodium amalgam* has little action, but forms a small quantity of allyl alcohol (Törnøe, B. 21, 1282; cf. Buff, A. Suppl. 5, 247).—19.  $\text{H}_2\text{SO}_4$  forms oily  $\text{C}_2\text{H}_5\text{Cl}(\text{OH})(\text{SO}_3\text{H})$  (Oppenheim, B. 3, 735).—20. Oxidised by  $\text{HNO}_3$  to chloro-oxo-propionic acid.—21. *Alcoholic or strong aqueous ammonia* forms gummy  $\text{C}_2\text{H}_5\text{ClNO}_2$  (?) Gaseous ammonia reacts in the cold forming  $\text{N}(\text{C}_2\text{H}_5\text{Cl}.\text{OH})_2$  [93°] which forms a crystalline hydro-chloride [173°], and is converted by alkalis into a substance resembling gelatin (Fauconnier, C. R. 107, 115).—22. *Triethylamine* at  $100^\circ$  gives rise to crystalline  $\text{C}_2\text{H}_5\text{O}.\text{NEt}_3\text{Cl}$  (Reboul, C. R. 93, 423).—23. *Aniline* at  $140^\circ$  forms oily  $\text{C}_6\text{H}_5\text{N}_2\text{O}$ , the constitution of which is probably  $\text{CH}_3\text{NHPH}.\text{CH}(\text{OH}).\text{CH}_2\text{NHPH}$ . [54°] ( $290^\circ$  at 10 mm.). It forms a hydrochloride  $\text{B}^+\text{H}_2\text{Cl}_2$  [202°] crystallising in needles, insol. ether, sol. alcohol and water, which gives the reactions usually characteristic of alkaloids (Fauconnier, C. R. 106, 605; 107, 250).—24. *Zinc and allyl iodide* followed by water give chloro-hexenoic acid (c. v.), the first reaction being represented thus:  $\text{C}_6\text{H}_5\text{ClO} + \text{Zn} + \text{IC}_3\text{H}_7 = \text{C}_6\text{H}_5\text{Cl}(\text{OZnI})\text{C}_3\text{H}_7$  (Lo-patkins, Bl. [2] 41, 313).—25. *HGN* forms chloro-oxo-butyronitrile  $\text{C}_4\text{H}_7\text{Cl}(\text{OH})(\text{CN})$ , sol. water, alcohol, and ether (Hörmann, B. 12, 23).—26. *KCy* forms epicyanhydrin.—27. Boiling aqueous  $\text{KNO}_3$  forms  $\text{C}_2\text{H}_5\text{ClNO}_2$  [106°], crystallising in prisms (Thomsen, B. 11, 2136). It forms an acetyl derivative  $\text{C}_2\text{H}_5\text{AcClNO}_2$  [79°].

#### Chlorinated epichlorhydrins v. CHLORO-ACETONE.

Epichlorhydrin v. Di-CHLORO-PROPYLENE,  
Vol. II.

#### EPICYANHYDRIN $\text{C}_2\text{H}_5\text{NO}$ i.e.

$\text{CH}_3.\text{CH}.\text{CH}_2.\text{CN}$ . [163°]. From epichlorhydrin and aqueous  $\text{KCy}$  (free from alkali) in the cold (Pazschke, Z. [2] 5, 512; J. pr. [2] 1, 82). Broad prisms (from water). Hot fuming  $\text{HCl}$

converts it into  $\text{CH}_3.\text{CH}.\text{CH}_2.\text{CO}_2\text{H}$  [225°] which, by further heating with fuming  $\text{HCl}$  for 6 hours at  $160^\circ$  is reduced to *n*-butyric acid (Hartenstein, J. pr. [2] 7, 295).

#### EPIDODHYDRIN $\text{C}_2\text{H}_5\text{IO}$ i.e.

$\text{CH}_3.\text{CH}.\text{CH}_2.\text{I}$ . (160°–180°). S.G. 1.2–0.3. From epichlorhydrin and  $\text{KI}$  at  $100^\circ$  (Reboul, A. Suppl. 1, 227). Oil.

**EQUATIONS, CHEMICAL.** The formula of an element expresses a certain quantity of that element, and the formula of a compound represents the composition of a certain quantity of that compound. When elements and compounds interact chemically, other elements and compounds are produced; a chemical equation represents, primarily, the quantities of the interacting bodies and the products of the interaction, and the compositions of these bodies. The sum of the quantities of the interacting bodies is equal to the sum of the quantities of the products of the interaction. A chemical equation then represents the distribution of the bodies which take part in a chemical change before the change begins and when the change is completed. But the equation does not give a full account of the transaction; thus the equation  $\text{Zn} + \text{H}_2\text{SO}_4 = \text{ZnSO}_4 + \text{H}_2$  tells that, if zinc and sulphuric acid react to produce zinc sulphate and hydrogen, then 98 parts by weight of sulphuric acid react with 65.2 parts of zinc, and the quantities of zinc sulphate and hydrogen produced are represented by the numbers 161.2 and 2, respectively. The equation does not indicate the conditions which must be fulfilled in order that zinc and sulphuric acid shall react to produce zinc sulphate and hydrogen; as a matter of fact a considerable quantity of water must be present. Again, the equation  $\text{CaCl}_2 + \text{Na}_2\text{CO}_3 = 2\text{NaCl} + \text{CaCO}_3$  merely asserts that when calcium chloride and sodium carbonate react to produce sodium chloride and calcium carbonate, for every 111 parts of calcium chloride changed 106 parts of sodium carbonate are also changed, but it does not tell that in order to effect the change of 111 parts of calcium chloride into calcium carbonate much more than 106 parts of sodium carbonate must be present although only 106 parts are actually chemically changed. An equation often represents a chemical occurrence as more simple than it really is. For instance, the equation  $\text{FeCl}_3 + 3\text{KCN} = \text{Fe}(\text{CNS})_3 + 3\text{KCl}$  seems to imply that if 162.5 parts of ferric chloride were mixed with 291 parts of potassium sulphocyanide, 280 parts of ferric sulphocyanide and 223.5 parts of potassium chloride would be produced; but in order to change 162.5 parts of ferric chloride to ferric sulphocyanide something like  $800 \times 291$  parts of potassium sulphocyanide must be present, although only 291 parts of the sulphocyanide are actually chemically changed.

F F

When the bodies which take part in a chemical change are gaseous the equation represents the volumes of the gases which react and are produced; thus the equation  $\text{H}_2 + \text{O} = \text{H}_2\text{O}$  tells that if hydrogen is combined with oxygen to form water-gas, then the volume of hydrogen is double that of the oxygen and is equal to that of the water-gas formed. The formula of a compound gas always represents the composition of that mass of the gas which occupies twice the volume occupied by one part by weight of hydrogen at the same temperature and pressure as the gas in question. The symbols of some elements represent those masses of the gaseous elements which occupy the same volume as one part by weight of hydrogen, *e.g.* Cl, O, N, Br; but there are several exceptions to this statement, *e.g.* the symbols P and As represent masses of phosphorus and arsenic which, as gases, occupy half the volume occupied, at the same temperature and pressure, by unit mass of hydrogen, and the symbols Hg and Cd represent masses of mercury and cadmium which, as gases, occupy twice the volume occupied by unit mass of hydrogen.

Chemical equations which represent changes of composition occurring among gases may also be read in the language of the molecular and atomic theory; as thus regarded they tell the ratio between the numbers of molecules of the reacting bodies and the ratio between the numbers of molecules of the products of the reaction; the equations also represent the distribution of the atoms of the elementary constituents of the reacting bodies and the bodies produced. Thus the equation  $2\text{H}_2 + \text{O}_2 = 2\text{H}_2\text{O}$  tells that when hydrogen and oxygen combine to form water, two molecules of hydrogen react with one molecule of oxygen to produce two molecules of water-gas, and also that the hydrogen and oxygen molecules are diatomic, and that the molecule of water-gas is composed of two atoms of hydrogen and one atom of oxygen. It is often the custom to regard the formulae of liquid and solid bodies as molecular, and so to regard every equation as an expression of the molecular and atomic distribution of the bodies taking part in the chemical change; but to do this at present is to go further than is justified by the molecular and atomic theory (*cf.* *ATOMIC AND MOLECULAR WEIGHTS*, vol. i. 347-350). In connexion with chemical equations *v. FORMULÆ*.

M. M. P. M.

**EQUILIBRIUM, CHEMICAL.** The nature of the problems which we shall discuss in this article may best be illustrated by considering a few simple cases. The simplest we can take is when a given quantity of such a substance as  $\text{H}_2\text{O}$  which can exist at ordinary temperatures in both the liquid and gaseous states is placed in a closed vessel of given volume; then if in this volume we have a given quantity of  $\text{H}_2\text{O}$ , the system will arrive at, and remain in, a state in which the quantities of steam and water have definite values, say  $\alpha$  and  $\beta$  respectively; if on the introduction of the  $\text{H}_2\text{O}$  the quantity in the gaseous state was greater than  $\beta$ , condensation will take place until it is reduced to  $\beta$ ; if on the contrary the quantity was less than  $\beta$ , evaporation will take place until it reaches this value. Another case analogous to this, but in which the two states are the solid and the gaseous, is when

instead of water and steam we have solid paracyanogen and gaseous cyanogen; in this case, as Troost and Hautefeuille (*C. R.* 68, 785, 795) have shown, the system attains a state in which the pressure of the cyanogen gas has a definite value depending upon the temperature. Another example is when a substance can exist in two allotropic forms, such as phosphorus in its red and yellow modifications; if a given quantity of phosphorus be heated in a closed vessel it will attain a state in which the quantities of the red and yellow modifications have definite values (*v.* Troost and Hautefeuille, *A. Ch.* [5] 2, 153). The phenomena of dissociation afford excellent examples of chemical equilibrium;  $\text{N}_2\text{O}$ , for example dissociates into  $\text{NO}$ , but if the gas is contained in a closed vessel the dissociation does not go on indefinitely, but only until a certain proportion of the gas has been dissociated, after which no further change takes place in the gas if the temperature and pressure remain constant. A more general case of chemical equilibrium is when solutions of sulphuric and nitric acids, and nitrate and sulphate of sodium are mixed together; chemical changes will go on until a state is reached in which there is a certain relation between the masses of the four substances present; after this no further change will take place in the constitution of the mixture.

In this article we shall discuss the relations which in cases like these exist between the quantities of the various substances, or the quantities of the same substance in different states, when there is equilibrium, and the way in which this relation is affected by alterations in the physical conditions, such as changes in pressure, temperature, intensity of magnetisation, and so on.

Having seen the nature of the problems with which we have to deal, it will be well to consider how chemical equilibrium resembles or differs from ordinary dynamical equilibrium. In the first place all chemical systems seem to reach a steady state, while it is only under exceptional circumstances that frictionless dynamical systems do so. Again, as far as our knowledge extends, a chemical system gradually approaches the state of equilibrium, and when it has once reached it, remains in it; nothing corresponding to the oscillations of a dynamical system about its position of equilibrium seems to have been observed. The dynamical systems whose behaviour most closely resembles that of the chemical systems are those in which the friction is very large or the inertia very small; such systems always get into a steady state and sink gradually into it without ever passing through it.

#### COMPLETE AND PARTIAL EQUILIBRIUM.

In the examples of chemical equilibrium previously considered, the state of the mixture is definite when given quantities of various chemical elements are present under identical physical conditions. Such a system may be said to be in 'complete' equilibrium. There are many cases, however, in which quite a different state of things obtains; thus at low temperatures we may have given quantities of hydrogen and oxygen in equilibrium when arranged in an infinite number of ways, for, since steam, hydrogen, and oxygen do not combine at such temperatures, we may divide the hydrogen and oxygen in any

proportion between  $\text{H}_2\text{O}$ ,  $\text{O}_2$ , and  $\text{H}_2$ , and yet still have equilibrium. The reason for the difference between this case and the previous one is obvious: here the system has no (chemical) freedom and must stay in whatever (chemical) state it was placed initially; in the previous cases, on the other hand, the quantities of any of the substances could both increase and decrease: thus in the case of the water and steam, the water could evaporate and the steam condense; in the dissociation of  $\text{N}_2\text{O}_4$ , the  $\text{N}_2\text{O}_4$  could split up and the  $\text{NO}_2$  combine; such cases are said to be 'reversible' and are characterised by the physical and chemical conditions being such that processes can occur by which the quantities of any of the substances can both increase and decrease; in these cases the quantities of the acting substances may be regarded as variable quantities, and when there is equilibrium there will be a definite relation between them. If, however, the circumstances are such that processes producing both increase and decrease of the quantities of the substances cannot occur, then we can no longer regard these quantities as variables, and there will not be the same relation between them as if such changes could take place; we may call the equilibrium in this case 'partial' equilibrium; it is definite with respect to the physical conditions but not with respect to the chemical. Thus in the case of the oxygen and hydrogen at low temperatures, the quantities of steam, hydrogen, and oxygen, must be regarded as constants, and equilibrium may subsist with any values for these quantities; if, however, we raise the temperature to such a point that the oxygen and hydrogen can combine and the steam be decomposed, the quantities of hydrogen, oxygen, and steam may now be regarded as variables, and there will be a definite relation between them when there is equilibrium.

The case of oxygen and hydrogen at low temperatures is a somewhat extreme one, as no chemical action at all goes on; there are, however, cases in which some of the quantities may change, but only in one way, they can increase but not diminish, or *vice versa*. Thus at low temperatures  $\text{HI}$  can be decomposed by light, while  $\text{H}$  and  $\text{I}$  cannot combine, so that the action is irreversible, and Lemoine has shown that when a mixture of  $\text{HI}$ ,  $\text{H}$ , and  $\text{I}$  is exposed to the action of light the decomposition of the  $\text{HI}$  goes on indefinitely.

In order to enable those processes to go on which cause the state of the system to be reversible, something more than the mere collisions between the molecules of the substances seems to be required; in fact, collisions alone seem unable to effect the decomposition of molecules of simple composition. We shall see evidence of this when we consider the phenomena attending dissociation, but considerable evidence may be derived from the fact that it is extremely difficult in many cases to get two pure gases to enter into chemical combination, though they readily do so when a small quantity of a properly-chosen third substance is introduced, which by secondary chemical actions may be supposed to effect the decomposition of the molecule. Examples of this are afforded by Dixon's experiments on the difficulty of making  $\text{CO}$  and  $\text{O}$  combine when perfectly dry, though they do so

readily when moist (*T.* 1884, 617). Pringsheim (*W. A.* 32, 384) has lately shown that perfectly dry chlorine and hydrogen do not explode when exposed to light. The change in the conditions required to enable the molecules to be decomposed is often exceedingly small. The most striking illustrations of this are furnished by catalytic agents, such as spongy platinum, which, while remaining to all appearance unchanged themselves, are yet able to alter completely the conditions of the system in which they are placed. We may suppose that the system before the introduction of these agents was in partial equilibrium only, in consequence of certain decompositions and recombinations not being able to take place, perhaps because the collisions alone were unable to split up the molecules; but that when these agents are introduced secondary chemical actions produce decomposition of the molecules, and so render all the processes reversible, the equilibrium which was before only partial becoming complete. Since a system in 'partial' equilibrium may be widely disturbed by the introduction of an excessively small change of some kind (such as the presence of a minute quantity of spongy platinum), it corresponds to what in dynamics is called unstable equilibrium, and might have been called so here if it were not rather straining the customary use of the word to apply it to a state which may last for an indefinite time. On the other hand, if a very small quantity of a catalytic agent were introduced into a system in 'complete' equilibrium, it would not produce a finite change; such a state corresponds to what in ordinary dynamics is called stable equilibrium. We may regard catalytic agents as reducing a system from partial to complete equilibrium.

The difference between 'partial' and 'complete' equilibrium may be summed up as follows: when a system is in 'partial' equilibrium the quantities of some of the constituents may be altered without any change in the others while in 'complete' equilibrium a change in the quantity of one of the constituents involves a change in the quantities of some or all of the others. The introduction of an indefinite, small amount of a third substance, or the communication of an indefinitely small quantity of energy, to a system in 'complete' equilibrium will only produce an indefinitely small change in the state of equilibrium, while the state of system in 'partial' equilibrium may be profoundly modified by the same means.

#### KINEMATICAL METHODS OF CONSIDERING CHEMICAL EQUILIBRIUM.

We must now go on to discuss the theory of chemical equilibrium, considering at first the case where the equilibrium is 'complete.' The question may be discussed from two points of view—the one kinematical, the other dynamical. We shall begin with theories founded upon kinematical principles, as, though their application is more limited than those based upon dynamical ones, yet as far as they go they afford us a clearer view of the subject, and are therefore better fitted for an introduction to it. They have also the advantage over the dynamical theories of giving us some information about the behaviour of the system before it reaches the state of equilibrium.

The kinematical theories depend upon the conception which we owe to Clausius and Williamson, that in reversible chemical processes, such as the dissociation of a gas, the molecules of the gas are continually splitting up, and the atoms which are thus produced are continually recombining. When the state of equilibrium is reached the number of molecules decomposed in unit time must equal the number formed in the same time by the recombination of the atoms. Let us now consider the application of these principles to the simplest case of chemical combination we can choose, that of the dissociation of a diatomic gas into atoms. Since the molecules are continually splitting up, the time each molecule exists without decomposition is finite, and though this may vary from molecule to molecule the mean of such time will, however, be finite, and we shall call it the 'paired' time of the molecule and denote it by  $t_1$ . The mean time an atom remains alone and free from other atoms, we shall call the 'free' time, and denote it by  $\tau$ ; since an atom in order to recombine must come close to another atom, the time an atom remains free will be inversely proportional to the number of collisions it has with other atoms, and therefore inversely proportional to the number of such atoms in unit volume. We may therefore put  $\tau = \frac{\tau}{n}$ ,

where  $n$  is the number of free atoms in unit volume. To simplify the calculations, let us suppose that the time each molecule remains paired is the same for all molecules and equal to the paired time, and that the time an atom is free is the same for all atoms and equal to the free time. Then if  $N$  be the number of molecules in unit volume, the number of molecules which split up in a short time,  $\delta t$ , will be  $\frac{N\delta t}{t_1}$ , for we may suppose that the rate at which the molecules split up remains constant for the time  $t_1$ , but if so,  $N$  will split up during this time, so that the number which splits up in unit volume in the time  $\delta t$  will be  $\frac{N\delta t}{t_1}$ ; similarly the number of atoms which pair in the time  $\delta t$  will be  $\frac{n}{\tau}\delta t$ , that is  $\frac{n^2}{\tau}\delta t$ . Thus, if  $\delta N$  is the increase in time  $\delta t$  in the number of molecules in unit volume,

$$\delta N = \left( \frac{1}{2} \frac{n^2}{\tau} - \frac{N}{t_1} \right) \delta t$$

$$\text{or} \quad \frac{dN}{dt} = \frac{1}{2} \frac{n^2}{\tau} - \frac{N}{t_1};$$

$$\text{similarly,} \quad \frac{dn}{dt} = \frac{2N}{t_1} - \frac{n^2}{\tau}.$$

When the gas has reached a steady state  $\frac{dN}{dt}$  and  $\frac{dn}{dt}$  both vanish, so that  $\frac{n^2}{N} = 2\tau$ . . . (1)

From this expression we can find the vapour density of the gas when it is in the steady state. Let  $\Delta$  be the density of the normal gas, and  $\Delta'$  that of the dissociated gas at the same pressure; then, if  $S$  is the number of molecules in unit volume of the normal gas before dissociation,

$$\frac{\Delta'}{\Delta} = \frac{S}{N+n} = \frac{S}{S+\frac{n}{2}}.$$

$$\text{Hence,} \quad n = \frac{2S(\Delta - \Delta')}{\Delta'},$$

$$N = \frac{S(2\Delta' - \Delta)}{\Delta'}.$$

So that equation (1) becomes

$$\frac{2(\Delta - \Delta')^2}{(2\Delta' - \Delta)\Delta'} S = \frac{\tau}{t_1}.$$

But if the temperature remains constant  $S$  is proportional to the initial pressure  $p$ , so that we may write this equation as

$$\frac{p(\Delta - \Delta')^2}{(2\Delta' - \Delta)\Delta'} = (\text{a constant}) \frac{\tau}{t_1} \quad . \quad (2)$$

The result that  $\frac{p(\Delta - \Delta')^2}{(2\Delta' - \Delta)\Delta'}$  is constant, was

obtained by Willard Gibbs from thermodynamical considerations, and was shown by him (*Am. S.* 17, 277) to agree with the results of experiments on the vapour densities at different pressures of nitrogen peroxide, and acetic and formic acids. More recently a most elaborate determination of the vapour density of nitrogen peroxide at different pressures has been made by E. and L. Natanson (*W. A.* 24, 454), with the result that at a constant temperature  $\frac{p(\Delta - \Delta')^2}{(2\Delta' - \Delta)\Delta'}$  is constant. The preceding investigation shows that when a dissociable gas obeys this law  $\frac{\tau}{t_1}$  must be independent of the density, and therefore, since  $\tau$  does not depend upon the pressure,  $t_1$  cannot do so; but if  $t_1$  is independent of the pressure, the decomposition of the more complex molecules cannot be produced by collisions with molecules or atoms of the same kind, for if it were  $t_1$  would diminish as the pressure increased. There does not appear to be any reason for supposing that on the kinetic theory of gases the collisions between the molecules must of necessity produce decomposition. There must be a limit to the velocity with which a particle is moving, for it is evident that the kinetic energy possessed by a single particle must be less than the kinetic energy in the smallest quantity of the gas which exhibits the property of the gas when in bulk. Thus, if a million molecules are sufficient to make the gas possess this property, the greatest value of the square of the velocity of a molecule would be a million times the velocity of mean square at this temperature, and therefore the square of the relative velocity of the atoms in a molecule after being struck by another molecule must be less than this value. The atoms in the molecule will not, however, part company unless the square of the relative velocity exceeds a certain value, depending upon the distance between the molecules, the law of force between them, and the intensity of this force at unit distance, so that the force may be so intense and the atoms so near that to split up the molecule the relative velocity of the atoms would have to be greater than that which could be produced by a collision with any molecule in the gas.

To return to formula (1), we see that if  $x$  denotes the ratio of the number of dissociated atoms,  $n$ , to  $S$ , the number of molecules originally present in unit volume, then

$$x^2 + x \frac{\tau}{t_1 S} = \frac{2\tau}{t_1 S} \quad (3)$$

or if only a small fraction of the molecules is dissociated

$$x^2 = \frac{2\tau}{t_1 S}$$

so that in this case the amount of dissociation is inversely proportional to the square root of the pressure.

By observing the amount of dissociation when the gas is in equilibrium, we can determine

$x$ , and hence by equation (3)  $\frac{\tau}{t_1 S}$  or  $\frac{x\tau}{t_1}$

this latter quantity is  $x$  times the ratio of the free to the paired time, so that by determining the vapour pressure of a gas when in a steady state, we can determine the ratio of its free to its paired time. Thus by comparing equation (3) with the result of Lemoine's experiments on the dissociation of HI, we find that, under atmospheric pressure, at 1250° the paired time is 1.32 times the free time, and at 900° only  $\frac{1}{2}$ . We cannot, however, by observations on the gas in the steady state determine the value of either of these times absolutely; if, however, we have determined their ratio in this way, we can, by observing the velocity of dissociation, determine the 'free' time of the atoms, for from equation (1) we have:

$$\begin{aligned} \frac{dn}{dt} &= \frac{2N}{t_1} - \frac{n^2}{\tau} \\ &= \frac{2S - n}{t_1} - \frac{n^2}{\tau} \end{aligned}$$

If we denote  $\frac{\tau}{t_1 S}$  by  $c$ , which can be found by observations on the steady state of the gas, the solution of this differential equation, if

$$a = S \left( 2c + \frac{c^2}{4} \right)$$

$$\text{is } \frac{1}{2a} \log \frac{(n + \frac{1}{2}Sc - a)(n_2 + \frac{1}{2}Sc + a)}{(n_1 + \frac{1}{2}Sc + a)(n + \frac{1}{2}Sc - a)} = -\frac{t}{\tau} + \text{constant,}$$

so that if  $t_1$  is the time required for the number of atoms to increase from  $n_1$  to  $n_2$

$$\frac{1}{2a} \log \frac{(n_1 + \frac{1}{2}Sc - a)(n_2 + \frac{1}{2}Sc + a)}{(n_1 + \frac{1}{2}Sc + a)(n_2 + \frac{1}{2}Sc - a)} = \frac{t_1}{\tau} \quad (4)$$

Hence, if we observe the time taken for the dissociation of a known fraction of the gas we shall be able to find from this equation the 'free time,' and then, as from observations on the steady state we know the ratio of the paired to the free time, we can find the paired time.

The same principles can be applied to more complicated cases of equilibrium, such as the combination of hydrogen and iodine to form hydriodic acid. We shall suppose that the molecules of hydrogen and iodine and hydriodic acid are continually splitting up into atoms, and that these atoms are constantly recombining and forming molecules. In this case we have five things to consider, the hydrogen molecules

and atoms, the iodine molecules and atoms, and the hydriodic acid molecules.

Let  $m$  and  $n$  be the number of hydrogen atoms and molecules respectively;

$p$  and  $q$  the number of iodine atoms and molecules;

$r$  the number of hydriodic acid molecules;

$t_1, t_2, t_3$ , the times two atoms remain paired together in the hydrogen, iodine, and hydriodic acid molecules, respectively;

$\frac{1}{m'}, \frac{1}{n'}$  the times a hydrogen atom is free from a hydrogen and iodine atom respectively;

$\tau_1$  the time an iodine atom is free from another iodine atom;

$M$  and  $N$  the total number of hydrogen and iodine atoms respectively, whether free or in combination with other atoms.

Then by the same reasoning as in the case of dissociation:

$$\frac{dm}{dt} = \frac{2n}{t_1} + \frac{r}{t_2} - \frac{2m^2}{\tau_1} - \frac{mp}{\tau_2}$$

$$\frac{dn}{dt} = \frac{m^2}{\tau_1} - \frac{n}{t_1}$$

$$\frac{dp}{dt} = \frac{2q}{t_2} + \frac{r}{t_3} - \frac{2p^2}{\tau_2} - \frac{mp}{\tau_2}$$

$$\frac{dq}{dt} = \frac{p^2}{\tau_2} - \frac{q}{t_2}$$

$$\frac{dr}{dt} = \frac{mp}{\tau_2} - \frac{r}{t_3}$$

$$m + 2n + r = M$$

$$p + 2q + r = N$$

When the system has got into a steady state,  $m, n, p, q, r$  are all constant, so that the above equations may be written:

$$\frac{m^2}{\tau_1} = \frac{n}{t_1}; \quad \frac{p^2}{\tau_2} = \frac{q}{t_2}; \quad \frac{mp}{\tau_2} = \frac{r}{t_3} \quad (5)$$

In solving these equations we may assume that the number of free atoms of hydrogen or iodine is very small compared with the number of molecules; so that  $n = \frac{1}{2}(M - r)$  and  $q = \frac{1}{2}(N - r)$ ; hence from equation (5) we get:

$$\frac{\tau_1^2}{\tau_1 \tau_2} r^2 = \frac{t_2^2}{4t_1 t_2} (M - r)(N - r) \quad (6)$$

If equivalent quantities of hydrogen and iodine are present  $M = N$  and we have:

$$r = \left\{ \frac{1}{4} \frac{t_2^2 \tau_1 \tau_2}{t_1 t_2 \tau_2^2} \right\}^{\frac{1}{2}} (M - r).$$

In this case the ratio  $\frac{r}{M}$  is independent of the pressure.

Lemoine has made a very extensive series of experiments on the combination of hydrogen and iodine (*A. Ch.* [5] 11). In the following table the results of his experiments are compared with those given by equation (6); the value of  $\frac{t_2^2 \tau_1 \tau_2}{t_1 t_2 \tau_2^2}$  being determined by making the observed and calculated results agree when  $N = M$ .

*Combination of hydrogen and iodine at 440°.*

Proportion of H + I.	Ratio of free hydrogen to the total quantity of hydrogen.
	Observed.      Calculated.
H + I	.240      .240
H + .794I	.350      .342
H + .527I	.547      .519
H + .258I	.774      .750

We see too from equation (6) that if  $M$  is very large compared with  $N$ , then  $r = N$ ; that is, if the iodine is enormously in excess, the whole of the hydrogen is combined with iodine; in other other words there is no dissociation of the hydriodic acid; the effect of an excess of either hydrogen or iodine on the dissociation of HI is given by equation (6).

We could make other assumptions about the way in which the hydriodic acid was formed from the hydrogen and iodine which would lead to the same results for the equilibrium condition, but which could be distinguished from the preceding assumptions by observations on the rate at which dissociation takes place. Thus we might suppose that the combination of hydrogen and iodine takes place by a molecule of hydrogen coming close to one of iodine, and that these molecules emerge from the collision as two molecules of hydriodic acid. The decomposition of the hydriodic acid might be supposed to be caused by two of its molecules coming into collision and emerging as two molecules of hydrogen and iodine. In this case, if  $n$ ,  $q$ ,  $r$ , represent the number of molecules of hydrogen, iodine, and hydriodic acid respectively,  $\frac{r}{t_1}$  the time a molecule of iodine exists without

combining with one of hydrogen,  $\frac{r}{t_2}$  the time a molecule of hydriodic acid exists without combining with another to form two molecules of hydrogen and iodine; then

$$\frac{dr}{dt} = \frac{mq}{t_1} - \frac{r^2}{t_2}$$

and when there is equilibrium

$$mq = \frac{t_1}{t_2} r^2$$

This is an equation of exactly the same form as that previously obtained on the other hypothesis, so that by observations on the equilibrium condition we could not distinguish between them. The two hypotheses lead, however, to quite different expressions for the velocity with which various changes take place. Thus let us consider the rate at which a quantity of HI would dissociate according to the first hypothesis; in this case the initial rate of dissociation is given by

$$\frac{dr}{dt} = -\frac{r}{t_2}$$

according to the second

$$\frac{dr}{dt} = -\frac{r^2}{t_2}$$

Thus according to the first hypothesis the quantity of hydriodic acid dissociated in a short time is proportional to the pressure, while according to the second it is proportional to the square of the pressure, so that the two hypotheses could

readily be distinguished by observations on the rate of dissociation.

We can apply the above principles to any case of the combination of gases, but after what we have given, the reader will have no difficulty in making the investigation for himself, and we shall merely give the results.

Three monovalent gases, A, B, C, are mixed together; A can combine with both B and C to form the compounds AB and AC respectively, but B and C cannot combine; we wish to find how much of each compound is formed.

Let  $n$ ,  $q$ ,  $s$ ,  $u$ ,  $v$ , be the number of molecules in the steady state of A, B, C, AB, AC respectively, then we can prove

$$\frac{u^2}{v^2} = \frac{a\eta}{\beta\eta s} \dots \dots (7)$$

where  $a$  and  $\beta$  are constants, of which  $a$  does not depend upon C nor  $\beta$  upon B. Thus the number of molecules of the compound AB formed is proportional to the geometric mean of the number of free molecules of A and B, and similarly the number of molecules of the compound AC is proportional to the geometric mean of the number of free molecules of A and C.

We see from the equation that the same proportion of gases will enter into combination at all pressures. If  $M$ ,  $N$ ,  $P$  are the total number of atoms of A, B, C, respectively, in the vessel, then equation (7) may be written

$$\frac{u^2}{v^2} = \frac{1}{4} \frac{a(M-u-v)(N-u)}{\beta(M-u-v)(P-v)} \dots (8)$$

hence 
$$\frac{u^2}{v^2} = \frac{N-u}{P-v}$$

Suppose that C is largely in excess of A and B, then  $P-v$  will be large compared with  $N-u$ , so that  $v$  must be large compared with  $u$ , that is, C absorbs practically the whole of A, and only a very small quantity of the compound AB is formed; if, however, both A and C are largely in excess of B then there is very little free B, the whole of it being converted into AB. Equation (8) enables us to find how much of each compound is formed when the substances are mixed in any proportions.

Another case we can solve by the same principles is when we have four substances, A, B, C, D, such that if their molecules are represented by {A}, {B}, {C}, {D}; the way they act on each other is expressed by the equation

$$\alpha\{A\} + \beta\{B\} = \gamma\{C\} + \delta\{D\},$$

the action being reversible; that is, A and B act on each other to produce C and D, and C and D act on each other so as to produce A and B. Then if  $p$ ,  $q$ ,  $r$ ,  $s$  are the numbers of molecules of A, B, C, D respectively, we may prove by the method just described that

$$p^2 q^2 = \kappa r^2 s^2 \dots \dots (9)$$

when  $\kappa$  is independent of  $p$ ,  $q$ ,  $r$ , and  $s$ . If  $\alpha + \beta = \gamma + \delta$ , that is, if the chemical action does not produce a change in the number of molecules, the relative amounts of the substances produced by the action will be independent of the pressure. If  $P$ ,  $Q$ ,  $P'$ ,  $Q'$  are the masses of A, B, C, D present initially,  $\alpha t$ ,  $\beta t$  the number of molecules of A and B which have disappeared, and  $\gamma t$ ,  $\delta t$  the number of molecules of A and B which have ap

peared when equilibrium is reached, then equation (9) may be written

$(P - \kappa\xi)(Q - \beta\xi)^2 = \kappa(P' + \gamma\xi)(Q' + \delta\xi)^2$ . (10). Thus if  $P \cdot Q^2$  is greater than  $\kappa P' \cdot Q'^2$ ,  $\xi$  is positive, that is, the A and B molecules combine to form C and D; but if  $P \cdot Q^2$  is less than  $\kappa P' \cdot Q'^2$ ,  $\xi$  is negative, that is, the C and D molecules combine to form A and B; thus the nature of the chemical action depends on the relative amounts of the combining substances initially present. This is an example of what is called *mass action*, which we shall consider more in detail in the following paragraph. For other examples of the application of this method we may refer to a paper by J. J. Thomson on chemical combination (*P. M.* 18, 232).

#### Guldberg and Waage's Theory.

A theory of chemical action based to some extent on kinematical principles was given by Guldberg and Waage in 1867 (*Etudes sur les Affinités Chimiques*), and an extended application in 1879 (*J. pr.* 19, 63); the results of this theory have been compared by the authors and others with the results of a large number of experiments. The theory may perhaps best be illustrated by considering a special case. Let us suppose that we have four soluble substances, A, B, C, D, in solution, and that these substances are such that A by its action on B produces C and D, while C by its action on D produces A and B; we may suppose that the four substances are hydrochloric acid, sodium nitrate, nitric acid, and sodium chloride. Let  $p, q, r, s$  be the masses of these substances, respectively, expressed in gram-equivalents,  $v$  being the volume in which they are contained, then  $\frac{p}{v}, \frac{q}{v}, \frac{r}{v}, \frac{s}{v}$ , are called by Guldberg and Waage the *active masses* of the four substances, and they assume that the amount of A and B which in unit time changes into C and D is proportional to the product of the active masses, and may be expressed by

$$\kappa \frac{p}{v} \frac{q}{v},$$

where  $\kappa$  is what they call the coefficient of affinity of A and B; similarly the amount of C and D which in unit time passes into A and B is

$$\kappa' \frac{r}{v} \frac{s}{v},$$

where  $\kappa'$  is the coefficient of affinity of C and D. When the system is in equilibrium the amount of A and B which passes into C and D in unit time must equal the amount of C and D which passes into A and B, so that

$$\kappa pq = \kappa' rs,$$

or if P, Q, R, S, are the amounts of A, B, C, D, initially present, and  $\xi$  is the number of equivalents of A and B which change into C and D, this equation may be written,

$$\kappa(P - \xi)(Q - \xi) = \kappa'(R + \xi)(S + \xi) \quad (11)$$

This is a quadratic equation to determine  $\xi$ ; but we may easily show that it has only one admissible root, for if  $\xi$  is positive it must not be greater than the smaller of the quantities P and Q, and if negative it must not be greater than

the smaller of the two quantities R and S. This root is given by

$$\xi = \frac{\kappa(P + Q) + \kappa'(R + S)}{2(\kappa - \kappa')} \pm \sqrt{\left\{ \frac{\kappa(P + Q) + \kappa'(R + S)}{2(\kappa - \kappa')} \right\}^2 + \frac{\kappa PQ - \kappa' RS}{\kappa - \kappa'}}$$

the + or - sign being taken according as  $\kappa - \kappa'$  is negative or positive.

From equation (11) we see that if P is very much greater than Q, R, and S,  $Q - \xi$  must be very small, that is, nearly the whole of B must combine; thus if we mix a large quantity of hydrochloric acid with smaller quantities of NaCl, HNO<sub>3</sub>, NaNO<sub>3</sub>, nearly the whole of the NaNO<sub>3</sub> will be changed into NaCl. Again, if  $\kappa PQ$  is greater than  $\kappa' RS$ ,  $\xi$  is positive, but if less, then  $\xi$  is negative; thus the way the reaction goes will depend upon the relative amounts of the combining substances initially present. Thus, if, in the case before considered, the amounts of HCl and NaNO<sub>3</sub> are large compared with those of NaCl and HNO<sub>3</sub>, the reaction which goes on will be the conversion of NaNO<sub>3</sub> into NaCl and HNO<sub>3</sub>; but if the quantities of HCl and NaNO<sub>3</sub> are small compared with those of NaCl and HNO<sub>3</sub>, the reverse action will go on, and NaCl and HNO<sub>3</sub> will be converted into NaNO<sub>3</sub> and HCl. This effect of the quantities of the various substances in determining the nature of the chemical reaction is called *mass action*.

If we put  $P = Q$ ,  $R = 0$ ,  $S = 0$ , equation (11) becomes

$$\kappa(P - \xi)^2 = \kappa' \xi^2.$$

Now if P and R are acids, Q and S salts,  $\frac{\xi}{P - \xi}$  is the ratio in which the base divides itself between the acids A and B respectively, so that for this case  $\frac{\kappa}{\kappa'}$  is the square of the ratio in which the base divides itself between the acids.

#### Comparison of Guldberg and Waage's Theory with Experiment.

*Etherification.*—Guldberg and Waage have compared their theory with the results of the experiments of Berthelot and St. Gilles upon etherification (*A. Ch.* [3] 65, 385; 66, 1; 68, 225). If A, B, C, D are respectively acetic acid, water, ether, and alcohol, they find  $\frac{\kappa}{\kappa'} = 4$ . The

observed and calculated effects of mixing these substances in different proportions is given in the following table:—

Initial quantities of				Quantity of acetic acid which enters into combination	
acetic acid	water	ether	alcohol	observed	calculated
P	Q	R	S	$\xi$	$\xi$
1	0	0	1	.665	.667
1	0	0	2	.828	.845
1	0	0	4	.902	.980
2	0	0	1	.858	.845
1	0	1.6	1	.521	.493
1	3	0	1	.407	.409
1	23	0	1	.116	.131
1	98	0	2	.073	.073

*Division of a base between two acids.* Thomsen's experiments. Thomsen, by measuring the thermal changes accompanying the reaction, was able to calculate the distribution of the masses (Thomsen's *Thermochemische Untersuchungen*, I, 98). When A, B, C, D were respectively nitric acid, sodium sulphate, sulphuric acid, and sodium nitrate, Thomsen found that  $\frac{\kappa}{\kappa'} = 4$ , and when they were mixed in different proportions the results were given in the following table, where  $Q=1$ ,  $R=0$ ,  $S=0$  :—

P equivalents of nitric acid + 1 equivalent of sodium sulphate :—

P	$\xi$	Heat absorbed	
		observed	calculated
$\frac{1}{2}$	.121	452	462
$\frac{1}{3}$	.232	808	828
$\frac{1}{4}$	.423	1292	1331
$\frac{1}{5}$	.667	1752	1773
$\frac{2}{5}$	.845	2024	1974
$\frac{3}{5}$	.903	2050	2019

The following tables, derived from Thomsen's experiments, are given by Guldberg and Waage (*J. pr.* 19, 87) :—

Relative values of  $\kappa$ .

TABLE I.

Substance A	Substance D	$\kappa$
HCl	NaCl	1
HNO <sub>3</sub>	NaNO <sub>3</sub>	1
$\frac{1}{2}$ (H <sub>2</sub> SO <sub>4</sub> )	$\frac{1}{2}$ (Na <sub>2</sub> SO <sub>4</sub> )	.25
$\frac{1}{2}$ (H <sub>2</sub> C <sub>2</sub> O <sub>4</sub> )	$\frac{1}{2}$ (Na <sub>2</sub> C <sub>2</sub> O <sub>4</sub> )	.0676
H <sub>3</sub> PO <sub>4</sub>	NaH <sub>2</sub> PO <sub>4</sub>	.0625
$\frac{1}{2}$ (C <sub>2</sub> H <sub>3</sub> O <sub>2</sub> )	$\frac{1}{2}$ (C <sub>2</sub> H <sub>3</sub> NaO <sub>2</sub> )	.0025
$\frac{1}{2}$ (C <sub>2</sub> H <sub>3</sub> O <sub>2</sub> )	$\frac{1}{2}$ (C <sub>2</sub> H <sub>3</sub> NaO <sub>2</sub> )	.0025
C <sub>2</sub> H <sub>3</sub> O <sub>2</sub>	C <sub>2</sub> H <sub>3</sub> NaO <sub>2</sub>	.0009
HBO <sub>2</sub>	NaBO <sub>2</sub>	.0001

TABLE II.

Substance A	Substance D	$\kappa$
HCl	Chloride of a metal	1
$\frac{1}{2}$ (H <sub>2</sub> SO <sub>4</sub> )	sulphate	.25

where the metal may be potassium, sodium, or ammonium.

TABLE III.

Substance A	Substance D	$\kappa$
HCl	Chloride of a metal	1
$\frac{1}{2}$ (H <sub>2</sub> SO <sub>4</sub> )	sulphate	.5

where the metal may be Mg, Mn, Fe, Zn, Co, Ni, Cu. We see, therefore, that the value of  $\frac{\kappa}{\kappa'}$  is

almost independent of the nature of the base.

Ostwald repeated the experiments, using the change in volume of the solution to determine the distribution of the substances. The experiments are described and the results given in the *art. Aequilibrium* (vol. i. p. 75).

*Heterogeneous systems.*—So far we have only considered those cases in which the four substances are in the same condition, being either all soluble or all gaseous; we can, however, apply the same considerations to the case when one of them, D suppose, is an insoluble solid. In this case if the extent of surface of D exposed to the solution does not alter, its active mass is constant; thus, using the same notation as before, we must regard  $s$  as constant, and then the equation becomes

$$\kappa pq = \kappa' rs,$$

or since  $s$  is constant,

$$(P - \xi)(Q - \xi) = c(R + \xi),$$

where  $c$  is  $\frac{\kappa s}{\kappa'}$ . This expression has been verified by W. Engel (*J. pr.* 19, 94) for the case where A, B, C, D were respectively oxalic acid, chloride of calcium, hydrochloric acid, and calcium oxalate. The results are given in the following table :—

1 equivalent of calcium chloride + P equivalents of oxalic acid.

Oxalic acid	Quantity of calcium oxalate precipitated	
	observed	calculated
P	$\xi$	$\xi$
.398	.385	.385
.596	.569	.568
.795	.744	.736
.994	.873	.863
1.491	.967	.961
1.988	.973	.970
1.000	.863	.864

If two of the four substances, B and D, are insoluble, then if the surfaces remain constant their active masses are constant, and the equation

$$\kappa pq = \kappa' rs$$

will become

$$(P - \xi) = c(R + \xi),$$

where  $c$  is a constant and equal to  $\frac{\kappa s}{\kappa'}$ . This

expression has been tested by Guldberg and Waage for two cases (*J. pr.* 91, 92). The first case is when A, B, C, D are respectively potassium sulphate, barium carbonate, potassium carbonate, and barium sulphate; they found that when the system had reached its state of equilibrium, the quantity of potassium sulphate was  $\frac{1}{2}$  that of the potassium carbonate. The effect of mixing the substances in different proportions is given in the following table :—

Initial quantities of		Quantity combined	
potassium sulphate	potassium carbonate	observed	calculated
P	R	$\xi$	$\xi$
0	3.5	.719	.706
0	2.5	.500	.500
0	2	.395	.400
0	1 <sup>c</sup>	.176	.200
.25	2	.200	.200
.25	2.5	.300	.300
.25	3	.408	.400
.25	3.5	.593	.560
.50	2	trace	.000

The second case of this kind investigated by Guldberg and Waage was when A, B, C, D were respectively sodium sulphate, barium carbonate, sodium carbonate, and barium sulphate; they found that in this case when the system had reached its state of equilibrium the quantity of sodium sulphate was  $\frac{1}{2}$  of the quantity of sodium carbonate. The effect of mixing the substances in various proportions is given in the following table:—

Initial quantity of		Quantity combined	
sodium sulphate	sodium carbonate	observed	calculated
P	R	$\xi$	$\xi$
0	5	·837	·833
0	3·5	·605	·583
0	2	·337	·333
0	1	·157	·167
·2956	3	·234	·254
·2956	3·86	·438	·396
·2956	4·10	·440	·437
·2956	4·73	·558	·543

The method we previously described will lead to the same results for the equilibrium of heterogeneous substances as Guldberg and Waage's method.

The preceding instances show that in a large number of cases Guldberg and Waage's formula  $\kappa pq = \kappa' q' r$  represents accurately the state of equilibrium; nevertheless as given by Guldberg and Waage the formula must be regarded as almost empirical. The reasoning they give is only applicable to the special case of combination when the two molecules A and B after coming into contact separate as two molecules of A' and B'; the reasoning as they give it is not applicable to the case where the molecules of A and B have to split up into atoms before combination can take place, though if we use the kinematical method previously described we shall arrive at the same formula, in this case, if the chemical equivalents and the molecules are identical. The agreement of the formula with the experiments in some cases throws some light on the constitution of the molecules which take part in the reaction. Thus take the case represented by the equation

Now if the molecule of sodium nitrate is represented by  $\text{NaNO}_3$ , the molecule of  $\text{H}_2\text{SO}_4$  has to come into collision with two molecules of  $\text{NaNO}_3$ , simultaneously for combination to take place, and the number of such collisions is proportional to  $pq^2$ . Again the number of collisions which can give rise to the reverse chemical action will be proportional to  $rs^2$ , so that for equilibrium

$$\kappa pq^2 = \kappa' rs^2.$$

If we compare this formula with Thomsen's experiments on this reaction we shall find that it does not agree at all well with the results, while the formula  $\kappa pq = \kappa' rs$  does so. Again, if we consider the question from the dynamical point of view (v. p. 442) we shall also arrive at the equation  $\kappa pq^2 = \kappa' rs^2$ , if we assume that the molecule of sodium nitrate is represented by  $\text{NaNO}_3$ ; if on the other hand we assume that the molecule is represented by  $\text{Na}_2\text{N}_2\text{O}_6$ , both methods

lead to the equation  $\kappa pq = \kappa' rs$ , which is verified by experiment. Hence we conclude, either that the relative composition of the molecules is represented by the scheme  $\text{H}_2\text{SO}_4, \text{Na}_2\text{N}_2\text{O}_6, \text{Na}_2\text{SO}_4, \text{H}_2\text{N}_2\text{O}_6$ , or else that a salt solution is in no way analogous to a number of particles of the salt moving about in a volume equal to that of the solvent. It may be well to remark that we cannot get over the difficulty by assuming the above reaction to take place in two stages, thus

Ostwald's researches (v. AFFINITY) show that the ratio in which a base divides itself between two acids is generally independent of the nature of the base, though if one of the acids is  $\text{H}_2\text{SO}_4$ , there are exceptions to this rule. We may therefore regard  $\kappa$  as the product of two factors  $\alpha$  and  $\beta$ , of which  $\alpha$  depends only upon the acid and  $\beta$  only upon the base, while  $\kappa'$  will be the product of  $\beta$  and another factor  $\alpha'$  which depends only on the other acid; the ratio of  $\kappa$  to  $\kappa'$  will then be the same as the ratio of  $\alpha$  to  $\alpha'$ , and will depend only upon the acids. If we apply the method given on p. 436 to this case we can see how this may be brought about. Let us consider the reaction

Let  $p, q, r, s$  be the number of molecules of  $\text{HCl}, \text{NaNO}_3, \text{HNO}_3$ , and  $\text{NaCl}$  respectively,  $t_1, t_2, t_3, t_4$  the paired time of these molecules, and let  $x, y, s, w$  be the number of free atoms of  $\text{H}, \text{Cl}, \text{NO}_3$ , and  $\text{Na}$  respectively,  $\frac{y}{t_1}$  the time an atom

of  $\text{H}$  is free from one of  $\text{Cl}$ ,  $\frac{s}{t_2}$  the time an

atom of  $\text{H}$  is free from one of  $\text{NO}_3$ ,  $\frac{w}{t_4}$  the time an

atom of  $\text{Cl}$  is free from one of  $\text{Na}$ , and  $\frac{w}{t_3}$  the

time an atom of  $\text{NO}_3$  is free from one of  $\text{Na}$ ; then, by the method on p. 437, we have the following equations:—

$$\frac{dp}{dt} = \frac{xy}{t_1} - \frac{p}{t_1}$$

$$\frac{dq}{dt} = \frac{sw}{t_2} - \frac{q}{t_2}$$

$$\frac{dr}{dt} = \frac{xs}{t_3} - \frac{r}{t_3}$$

$$\frac{ds}{dt} = \frac{wy}{t_4} - \frac{s}{t_4}$$

So that when there is equilibrium

$$\frac{t_1 t_2}{t_1 t_2} pq = \frac{t_3 t_4}{t_3 t_4} rs \quad . \quad . \quad (12)$$

$t_1, t_2, t_3, t_4$  are the only quantities which depend upon the base. We may regard the salt as made up of two systems, the radicle and the base, held together by forces between them; these forces will depend upon the relative configuration of the two systems, and we may suppose that this force vanishes when the two systems have simultaneously the configurations  $\alpha$  and  $\beta$ . Now if  $T_1, T_2$  are the times of vibrations of the systems about the configurations  $\alpha$  and  $\beta$  respectively, the time which elapses between the two systems leaving this configuration and entering it again will, if

$T_1$  and  $T_2$  are incommensurable, be  $T_1 \times T_2$ , so that if the system can get into the state in which the force between them vanishes, the longest time they can exist without doing so will be  $T_1 \times T_2$ , and thus the paired time will be proportional to  $T_1 \times T_2$ . The two systems will probably vibrate approximately as if they were free, so that, approximately,  $T_1$  will only depend upon the radicle and  $T_2$  on the base; thus, since the base in NaCl is the same as in  $\text{NaNO}_3$ , the ratio of  $t_2$  to  $t_1$  will be independent of the base. Again, when the base and radicle come together again after having been dissociated, the force between them will depend upon their configuration, and we may suppose that unless the atoms are in certain configurations the force between them will not be sufficient to cause them to enter into combination. If  $T_1', T_2'$  are the times of vibration of the radicle and the base about these configurations, the time which will elapse between the systems leaving this configuration and entering it again will be  $T_1' \times T_2'$ , the longer these intervals are separated the less chance will there be of the system entering into combination, and the free time will be proportional to  $T_1' \times T_2'$ ; since one of these factors depends only on the base, and the other only upon the radicle,  $\frac{T_2}{T_1}$  will be independent of the base, and therefore by equation (12) the proportion in which the base divides itself between the two acids will be independent of the base. (For another method, partly kinematical, v. Pfaunder, *P. Jubelbd.* 182, 181, 55.)

#### DYNAMICAL METHODS.

In any dynamical system in a steady state there is a certain quantity called the Lagrangian Function ( $T - V$ , where  $T$  and  $V$  are respectively the mean kinetic and potential energies of the system) which reaches a maximum value when the system is in a steady state, and the knowledge of the expression for this quantity enables us to determine the configuration of the system when in this state. Exactly the same thing holds for the physical and chemical systems whose equilibrium we are now considering. It may be proved (see *Applications of Dynamics to Physics and Chemistry*, J. J. Thomson, chap. ix.) that when such systems are in a steady state their mean Lagrangian Function has a maximum value, and that all the circumstances of the equilibrium can be obtained by making use of this property. We shall for brevity call the mean Lagrangian Function, the quantity which has this property, the 'directrix' of the system, as the behaviour of the system is entirely regulated by this function.

The directrix is closely analogous to what in thermodynamics is called the entropy of the system, and the theorem that in the steady state the 'directrix' is a maximum is analogous to Clausius' theorem that the entropy of the system tends to a maximum. Willard Gibbs (*Equilibrium of Heterogeneous Substances*; *Am. S.* 16, 442), Horstmann (*B.* 12, 64), Liveing (*Chemical Equilibrium the result of the degradation of Energy*) (Planck, *W. A.* 80, 562; 81, 189; 82, 462), have treated the subject of chemical equilibrium from this point of view. As the problems can, however, be solved by purely mechanical

principles it seems preferable to do so. Though we can obtain the conditions of equilibrium both from mechanical principles and from the Second Law of Thermodynamics, it does not follow that we can therefore deduce the Second Law of Thermodynamics entirely from mechanical principles. The Second Law of Thermodynamics consists of two parts: one, that every distribution of heat tends to uniformity, by heat passing from places of higher to places of lower temperature; the other, that the entropy is a perfect differential; the second of these statements, but not the first, can be proved by purely dynamical principles. It must be remembered that what we show is that if the system does reach a steady state, the directrix must be a maximum; we cannot, however, prove that it must reach this state; this has to be deduced from observation.

In order to apply this method to find the conditions of equilibrium for chemical systems, we shall require the expressions for the directrix both for a mass of gas and a mass of liquid. If  $L_1$  be the directrix for a mass  $\xi$  of a gas, which obeys Boyle's Law, and whose density is  $\rho$ , and absolute temperature  $\theta$ , then (J. J. Thomson, *Applications of Dynamics*, chaps. x. and xi.)

$$L_1 = \xi R \theta \log \frac{p_0}{p} + \xi A \theta + \xi B \theta \log \theta - \xi V_1 \quad (13)$$

where  $R$ , is the value of  $\frac{p}{\rho \theta}$ ,  $p$  being the pressure;  $\rho$ ,  $A$ , and  $B$  are constants, and  $V_1$  is the mean potential energy of the molecules of unit mass of the gas.

The directrix  $L_2$  of a mass  $\eta$  of liquid, free from strain, electrification, &c., is given by the equation

$$L_2 = \eta \phi(\theta) - \eta V_2 \quad (14)$$

when  $\phi(\theta)$  is a function of the temperature, and  $V_2$  is the mean potential energy of the molecules of unit mass of the liquid. If the liquid is strained or electrified, or if it possesses energy in virtue of its surface tension, we can easily calculate the correction to the directrix; for, since the directrix is  $T - \bar{V}$ , all that we have to do is to calculate the potential energy arising from the strain, &c., and subtract it from the expression (14). Thus if the liquid is strained we must subtract from (14)  $\frac{1}{2} k V_s \sigma^2$ , where  $k$  is the bulk modulus of the liquid,  $V_s$  its volume when unstrained, and  $\sigma$  is the compression; again if the liquid has a free surface it will possess potential energy in virtue of its surface tension, equal to  $ST$  when  $S$  is the area of the surface and  $T$  the surface tension; to get the directrix in this case we must, therefore, subtract  $ST$  from the value given by (14).

To illustrate the method of solving problems by this principle, let us take the case of the evaporation of a liquid in a closed vessel. We have here two systems to consider: the vapour and the liquid; if  $\xi$  is the mass of the vapour, which we shall assume to obey Boyle's Law, its directrix  $L_1$  is given according to (13) by

$$L_1 = \xi R \theta \log \frac{p_0}{p} + \xi A \theta + \xi B \theta \log \theta - \xi V_1;$$

while if  $\eta$  is the mass of the liquid, its directrix  $L_2$  is given by

$$L_2 = \eta \phi(\theta) - \eta V_2;$$

and if  $\Delta$  is the directrix of the whole system,

$$\Delta = L_1 + L_2.$$

When the system is in equilibrium  $\Delta$  must be a maximum, so that if we suppose a mass  $\delta\xi$  of the liquid to evaporate we must have in the state of equilibrium

$$\frac{d\Delta}{d\xi} = 0 \quad . \quad . \quad (15)$$

Since the sum of the masses of the vapour and liquid is constant  $\frac{d\eta}{d\xi} = -1$ , so that equation (15) leads to the relation

$$R\theta \log \frac{\rho_2}{\rho} + R\theta \log \frac{\rho}{\sigma} + A\theta + B\theta \log \theta - \phi(\theta) - (v_1 - v_2) = 0 \quad (16)$$

where  $\sigma$  is the density of the liquid. This gives the expression for the vapour density  $\rho$  of the liquid at the temperature  $\theta$ .

It may be well to consider this case more in detail. Let us suppose that we start with some of the liquid and no vapour: then the system will move so as to increase the directrix; now at first when  $\rho = 0$  the rate of increase of  $L_1$  with  $\xi$  is infinitely great, so that  $\Delta$  will increase if a small quantity of the liquid evaporates, and therefore, by the principle just stated, evaporation will take place; as more liquid evaporates the rate of increase of  $L_1$  gets smaller and smaller, until a point is reached where the increase in the directrix of the vapour, when a small quantity of the liquid evaporates, equals the diminution of the directrix of the liquid under the same circumstances; when this point is reached the directrix will be a maximum and the system will remain in this state. If the external circumstances alter so as to affect the rate of change of the directrix of either the vapour or liquid as evaporation goes on, it will alter the point at which equilibrium is reached. Thus, for example, suppose that the liquid is in the form of a spherical drop: then, in virtue of its surface tension, it will possess potential energy proportional to its surface; when it evaporates, the surface, and therefore the potential energy, will diminish; but since the directrix of the liquid is  $\bar{T} - \bar{V}$ , the diminution in the potential energy of the liquid when it evaporates will cause the directrix to diminish more slowly with evaporation than it would if the liquid were of such a form that the area of its surface did not change on evaporation. The evaporation will, therefore, have to go on further than before, in order that the rate of increase of the directrix of the vapour shall sink to that of the rate of diminution in the directrix of the liquid. The vapour pressure, therefore, when there is equilibrium will be greater when the liquid is in the form of drops than when its surface is plane. If the drop, however, had been electrified, then, since the electricity is not carried away by the vapour, the potential energy of the liquid will increase as evaporation goes on, and the drop gets smaller, so that the same reasoning as before will show that the vapour pressure over an electrified drop is less than over one which is not electrified. These cases are examples of a corollary from the principle we are considering, which may be stated generally by saying that when the physical environment of a system is changed, and the consequent

change in the directrix of the system increases as any physical process goes on, then this process will have to go on further in the changed state before equilibrium is reached than in the unchanged one, while if the change in the directrix diminishes as the process goes on it will not have to proceed so far. The principle that the directrix is a maximum in equilibrium readily enables us to calculate the change made in the extent to which the process goes on. Thus, in the case of evaporation, if  $\chi$  is the change in the directrix caused by any change in the conditions,  $\delta\rho$  the consequent change in the vapour pressure when there is equilibrium, then we can easily show that

$$\delta\rho = \frac{1}{R\theta} \frac{\rho\sigma}{\sigma - \rho} \frac{d\chi}{d\xi}.$$

In the case of the spherical drop,  $\chi$  is minus the potential energy due to surface tension, or if  $a$  be the radius  $-4\pi a^2 T$ , and since  $\frac{da}{d\xi} = -\frac{1}{4\pi a^2 \sigma}$  we get

$$\delta\rho = \frac{2\rho}{\sigma - \rho} \frac{T}{a} \frac{1}{R\theta}.$$

**Dissociation.**—We can apply the same principles to cases of dissociation: let us suppose that we have a gas A which dissociates into two others, B and C; let  $\xi, \eta, \zeta$  be the masses of these gases;  $\rho_1, \rho_2, \rho_3$  their densities;  $v_1, v_2, v_3$  the mean potential energy of unit mass of their molecules;  $R_1, R_2, R_3$  the values of  $\frac{p}{\rho\theta}$  for the three gases respectively; then if  $L_1, L_2, L_3$  are the directrices of the three gases

$$L_1 = \xi R_1 \theta \log \frac{\rho_2}{\rho_1} + \xi A_1 \theta + \xi B \theta \log \theta - \xi V_1;$$

with corresponding expressions for  $L_2$  and  $L_3$ .  $\Delta$ , the directrix of the whole system, is given by the equation

$$\Delta = L_1 + L_2 + L_3;$$

if  $v$  is the volume in which the gases are confined  $\rho_1 = \frac{\xi}{v}, \rho_2 = \frac{\eta}{v}, \rho_3 = \frac{\zeta}{v}$ . When the system has reached equilibrium,  $\Delta$  is a maximum and therefore  $\frac{d\Delta}{d\xi}$  is zero, if  $c_1, c_2, c_3$  are the combining weights of the gases A, B, C,

$$\frac{d\eta}{d\xi} = -\frac{c_2}{c_1} \text{ and } \frac{d\zeta}{d\xi} = -\frac{c_3}{c_1}.$$

So that the condition

$$\frac{d\Delta}{d\xi} = 0$$

leads to the equation

$$\begin{aligned} & R_1 \theta \log \frac{\rho_2}{\rho_1} - \frac{c_2}{c_1} R_2 \theta \log \frac{\rho_2}{\rho_1} - \frac{c_3}{c_1} R_3 \theta \log \frac{\rho_2}{\rho_1} \\ & - (R_1 \theta - \frac{c_2}{c_1} R_2 \theta - \frac{c_3}{c_1} R_3 \theta) + (A_1 - \frac{c_2}{c_1} A_2 - \frac{c_3}{c_1} A_3) \theta \\ & + (B_1 - \frac{c_2}{c_1} B_2 - \frac{c_3}{c_1} B_3) \theta \log \theta - (v_1 - \frac{c_2}{c_1} v_2 \\ & \quad - \frac{c_3}{c_1} v_3) = 0, \end{aligned}$$

or since

$$c_1 R_1 = c_2 R_2 = c_3 R_3$$

this may be written

$$\frac{\eta_{\zeta}^{\circ}}{\xi v} = C\theta^{\alpha} \frac{(v_1 - \frac{c_2}{c_1}v_2 - \frac{c_3}{c_1}v_3)}{R, \theta} \quad \dots (17)$$

Where  $C$  and  $\alpha$  are constants, in the case of the dissociation of an elementary gas into atoms, we must suppose  $B$  and  $C$  to be the same, so that  $\eta = \zeta$ ,  $c_2 = c_3 = \frac{1}{2}c_1$ ; thus equation (17) reduces to

$$\frac{\eta_{\zeta}^{\circ}}{\xi v} = C\theta^{\alpha} \frac{v_1 - v_2}{R, \theta} \quad \dots (18)$$

This equation is the same as that which we previously obtained from kinematical principles, but expresses in addition the way the dissociation varies with the temperature. Formulae derived from thermodynamical principles have been given by Willard Gibbs (*Equilibrium of Heterogeneous Substances*, p. 169) and Boltzmann (*W. A.* 22, 39). In Willard Gibbs's formula  $\alpha$  is equal to  $-1$ , and in Boltzmann's it is equal to zero. Natanson's experiments on the dissociation of  $N_2O$ , show that neither of these values of  $\alpha$  agrees well with the observations. We see from (17) that if we have given masses of the substances,  $\frac{\eta_{\zeta}^{\circ}}{\xi}$  is proportional to  $v$ , so that the greater the volume in which the gas is contained the greater is the dissociation. The effect of an excess of one of the products of the dissociation (*v. art. DISSOCIATION*) follows at once from (17).

$\frac{c_2}{c_1}v_2 + \frac{c_3}{c_1}v_3 - v_1$  is the increase in the potential energy when unit mass of the gas dissociates; it may be approximately measured by  $H$ , the amount of heat which must be supplied to the system to keep the temperature constant when unit mass dissociates; when dissociation is accompanied by an absorption of heat,  $H$  is positive, when by an evolution,  $H$  is negative. Introducing  $H$  into equation (17) we get

$$\frac{\eta_{\zeta}^{\circ}}{\xi v} = C\theta^{\alpha} e^{-\frac{H}{R, \theta}} \quad \dots (18)$$

so that if  $H$  be positive  $\frac{\eta_{\zeta}^{\circ}}{\xi v} = 0$  when  $\theta$  is 0, and, therefore, either  $\eta$  or  $\zeta$  must vanish, so that at the absolute zero of temperature there is no dissociation; when  $\theta$  is infinite  $\frac{\eta_{\zeta}^{\circ}}{\xi v}$  is infinite if  $\alpha$  be positive, i.e.  $\xi$  must vanish, and therefore all the gas be dissociated; if  $\alpha$  be zero  $\frac{\eta_{\zeta}^{\circ}}{\xi v}$  is finite, and there is a finite amount of dissociation; and if  $\alpha$  be negative  $\frac{\eta_{\zeta}^{\circ}}{\xi v}$  is zero, and there is again no dissociation. We see from (18) that the greater the thermal changes accompanying dissociation, other circumstances being the same, the smaller will be the amount of dissociation at a given temperature.

*Dilute solutions.*—So far we have only considered gases, but Van 't Hoff (*L'Equilibre chimique dans les systèmes gazeux ou dissous à l'état dilué*, *Archiv. Néerlandais*, 20, 239 (1887)) has pointed out that Pfeffer's experiments on the osmotic pressures produced by salts dissolved in water (*Pfeffer, Osmotische Untersuchungen*, Leip-

zig, 1887), and Raoult's experiments on the effect of dissolved salts on the freezing points of solutions (*A. Ch.* [6] 4, 401), show that the molecules of a salt in a dilute solution exert the same pressure as they would exert if they were in the gaseous state at the same temperature, and occupying a volume equal to that of the liquid in which the salt is dissolved, and that the pressure exerted by these molecules obeys Boyle's and Gay-Lussac's laws. This being so, the directrix for the salt dissolved in the liquid must be the same as that for an equal mass of gas filling the volume occupied by the liquid. The preceding remarks are strictly true for such solvents as benzene or alcohol, but when the solvent is water there are many exceptions to them; most inorganic acids and salts behave as if they exerted a greater pressure than this rule would indicate, and it has been suggested by Arrhenius that this is due to the dissociation of the salt in the solution, though in some cases it would be necessary to suppose that dissociation amounted to more than 95 p.c. in order to explain the effect. We must remember that this representation of the behaviour of a solution is founded on the hypothesis that the solvent merely sustains the particles of the salt or acid, and it would require to be modified if anything analogous to chemical combination took place between the salt and the solvent; as such combinations do undoubtedly in many cases take place, it does not seem necessary to call in the aid of extreme dissociation until it has been shown that the effects could not be explained as due to the chemical action between the salt and the water. The fact that in order to produce comparable osmotic pressures it is necessary to have in the solution the same number of chemical equivalents rather than the same number of molecules points also to this explanation. If we assume that the directrix of the dissolved salt is the same as that of an equal mass of the substance when gaseous and occupying the same volume, it is easy to calculate the conditions of chemical equilibrium between them. For, let us take the case where we have dilute solutions of four substances A, B, C, D, such that when A acts upon B it produces C and D, and when C acts upon D it produces A and B. Let  $\{A\}$ ,  $\{B\}$ ,  $\{C\}$ ,  $\{D\}$  represent the molecules of A, B, C, D respectively, and let the chemical action which takes place be represented by the equation

Let  $\xi$ ,  $\eta$ ,  $\zeta$ ,  $\epsilon$  represent the masses of these substances respectively, and let the directrices be

$$\xi R, \theta \log \frac{vp_1'}{\xi} + \zeta \{A, \theta + B, \theta \log \theta\} - \xi w_1$$

$$\eta R, \theta \log \frac{vp_2''}{\eta} + \eta \{A, \theta + B, \theta \log \theta\} - \eta w_2$$

$$\zeta R, \theta \log \frac{vp_3'''}{\zeta} + \zeta \{A, \theta + B, \theta \log \theta\} - \zeta w_3$$

$$\epsilon R, \theta \log \frac{vp_4'''}{\epsilon} + \epsilon \{A, \theta + B, \theta \log \theta\} - \epsilon w_4$$

where  $v$  is the volume of the solvent, let  $Q$  represent the directrix of the solvent,  $w_1$ ,  $w_2$ ,  $w_3$ ,  $w_4$ , being the potential energies of unit masses of the substances. If  $c_1$ ,  $c_2$ ,  $c_3$ ,  $c_4$  are the combining weights of the four substances, and  $d\xi$ ,

$1\eta$ ,  $d\zeta$ ,  $d\epsilon$  are corresponding increments in their masses; then the increments in the number of molecules of each of the substances are proportional to  $\frac{d\zeta}{c_1}$ ,  $\frac{d\eta}{c_2}$ ,  $\frac{d\zeta}{c_3}$ ,  $\frac{d\epsilon}{c_4}$ ; but by the nature of the reaction which goes on between these substances, the increments in the number of molecules must be proportional to  $a$ ,  $b$ ,  $-c$ ,  $-d$ , so that we have

$$\frac{d\zeta}{ac_1} = \frac{d\eta}{bc_2} = -\frac{d\zeta}{cc_3} = -\frac{d\epsilon}{dc_4} \quad \text{or} \quad \frac{d\eta}{d\zeta} = \frac{bc_2}{ac_1}, \quad \frac{d\zeta}{d\zeta} = -\frac{cc_3}{ac_1}, \quad \frac{d\epsilon}{d\zeta} = -\frac{dc_4}{ac_1} \quad (19)$$

Then, since in equilibrium the directrix is a maximum,  $\frac{d\Delta}{d\zeta}$  must vanish; from this condition, and remembering equation (19), and that  $R_1c_1 = R_2c_2 = R_3c_3 = R_4c_4$ , we get

$$\frac{\zeta^{\epsilon d}}{\xi^{\alpha \eta b}} = \phi(\theta) v + d - a - b \cdot \frac{1}{R_1 c_1} \frac{dw}{d\zeta} e^{-\frac{a}{R_1 c_1} \frac{dw}{d\zeta}} \quad (20)$$

when  $\phi(\theta)$  is a function of the temperature, and  $w = \xi w_1 + \eta w_2 + \zeta w_3 + \epsilon w_4$ .

The value of  $\frac{dQ}{d\zeta}$  will be zero if the properties of the solvent do not change as chemical action goes on; in any case since the solutions are very dilute the properties of the solvent may be assumed to be changed by an amount proportional to the quantity of the salt dissolved, so that  $Q$  will be a linear function of  $\xi$ ,  $\eta$ ,  $\zeta$ ,  $\epsilon$ , and therefore  $\frac{dQ}{d\zeta}$  will be independent of  $\zeta$ ; thus the existence of the term involving  $Q$  will not modify the form of the equation, but is at most equivalent to a slight alteration in the value of  $\frac{dw}{d\zeta}$ , the increase in the potential energy of the system when the mass of  $\xi$  is increased by unity. It may be shown (v. J. J. Thomson, *Applications of Dynamics to Physics and Chemistry*, p. 278) that

$$\phi(\theta) = c \cdot \theta^{\frac{1}{R_1 c_1} (a s_1 c_1 + b s_2 c_2 - c s_3 c_3 - d s_4 c_4)}$$

where  $s_1$ ,  $s_2$ ,  $s_3$ ,  $s_4$  are the specific heats of the substances A, B, C, D respectively.

Equation (20) will enable us to find the effects of pressure and temperature upon chemical combination.

**Effect of pressure.**—From equation (20) we see that, if  $a + b = c + d$ , then  $\frac{\zeta^{\epsilon d}}{\xi^{\alpha \eta b}}$  is independent of the volume; but if  $a + b > c + d$ , the number of the molecules is not altered by the chemical reaction, so that in this case the amount of combination is independent of the pressure; if  $a + b$  is greater than  $c + d$ , then the greater the volume  $v$  the smaller is the ratio  $\frac{\zeta^{\epsilon d}}{\xi^{\alpha \eta b}}$ . Now, the action of C upon D tends to diminish this ratio, while that of A on B tends to increase it, and if  $a + b$  is greater than  $c + d$  the number of molecules is increased when C acts upon D and diminished when A acts upon B. Thus, when chemical combination alters the number of molecules, the state of equilibrium depends upon

the volume of the solvent, and the effect of increasing the volume is to favour that reaction which is attended by an increase in the number of molecules. In other words, the chemical action which produces an increase in volume is hindered by pressure, while that which produces a diminution is helped by it. This is an example of the corollary stated on p. 443.

**Effect of temperature.**—In equation (20)  $\frac{dw}{d\zeta}$  represents the increment in the potential energy of the system when  $\xi$  is increased by unity, and may be approximately measured by the amount of heat given out when  $\xi$  diminishes by unity; if the combination of C and D is accompanied by the production of heat,  $\frac{dw}{d\zeta}$  is

negative, and therefore, when  $\theta$  is zero,  $\frac{\zeta^{\epsilon d}}{\xi^{\alpha \eta b}}$  is zero too, and therefore either  $\zeta$  or  $\epsilon$  must vanish; that is, the combination of C and D goes on until one of the components is exhausted; in other words, the reaction which is attended with the production of heat will go on as far as possible.

According to Berthelot's law of maximum work the reaction accompanied by the formation of heat goes on as far as possible at all temperatures; we see, however, from equation (20) that in reality it only does so at the absolute zero of temperature, though, if the reaction is accompanied by large thermal effects, the law will be an approximation to the truth for a considerable range of temperature.

This equation shows, too, that if there is any thermal effect at all, the relative affinities of two acids at the absolute zero of temperature is either zero or infinity.

If the substances obey Dulong and Petit's law

$$s_1 c_1 = s_2 c_2 = s_3 c_3 = s_4 c_4 = w, \text{ say;}$$

and then

$$\frac{\zeta^{\epsilon d}}{\xi^{\alpha \eta b}} = c \cdot \theta^{\frac{1}{R_1 c_1} (a + b - c - d)} \cdot \frac{a}{R_1 c_1} \frac{dw}{d\zeta}$$

If  $a + b$  is greater than  $c + d$ , then  $\frac{\zeta^{\epsilon d}}{\xi^{\alpha \eta b}}$  is infinite

when  $\theta$  is infinite, that is, the reaction accompanied by a diminution in volume goes on as far as possible at an infinitely high temperature. If  $a + b = c + d$ , that is, if the combination does not change the volume, the combination will only be partial at an infinitely high temperature.

We saw that Ostwald's experiments showed that in the case of an acid and two bases the value of

$$\left( \frac{\zeta}{c_3} \right)^c \left( \frac{\epsilon}{c_4} \right)^d \left( \frac{\xi}{c_1} \right)^a \left( \frac{\eta}{c_2} \right)^b$$

was independent of the nature of the base; equation (20) shows that for this to be the case the amount of heat given out, when the number of molecules of one of the salts increases by unity and that of the other diminishes by the same amount, must be independent of the nature of the base. Now Thomsen's thermochemical researches have shown that the heat of formation of a salt seems to be the sum of two parts

(v. Lothar Meyer, P. M. 23, 504), one of which depends only on the base and the other only on the acid. Thus, in the reactions of the kind we are considering, where we have two salts of the same base, one of which is formed while the other disappears, the thermal effects will be independent of the nature of the base. We see, therefore, that thermochemical investigations confirm Ostwald's results.

The greater the thermal effects which accompany the reaction the more rapidly will the conditions of equilibrium vary with the temperature.

By the principle enunciated on p. 442 we can readily find the effect of any alteration in the physical conditions on the amount of chemical combination which must take place before equilibrium is reached. Thus, take for example the effect of surface tension; if the energy due to the surface tension increases as a chemical action proceeds, then the larger the surface of the solution the smaller is the amount of this action which takes place before the condition of equilibrium is reached; in other words, the surface tension checks that reaction which is accompanied by an increase in that part of the energy of the system which depends upon surface tension. For illustration of the effect of surface tension on chemical action v. *Proc. Camb. Phil. Soc.* 1888. The same principle will show that if the coefficient of compressibility of the solution alters as chemical action proceeds, the amount of this action which takes place before equilibrium is reached will depend upon the pressure applied to the solution; since, if pressure is applied to the liquid, the energy of the system, and therefore its directrix, will alter as the chemical change proceeds. Again, if the coefficient of magnetisation alters as chemical combination goes on, the point at which equilibrium will be reached will depend upon the intensity of the magnetic field in which the solution is placed.

In fine, if the quantity of any kind of energy changes as chemical combination proceeds, the conditions for chemical equilibrium will depend on the amount of the energy possessed by the system.

The amount of the alteration in the value of  $\kappa$ , the value of  $\xi_{\text{act}}^{\text{ced}}$  produced by an alteration  $x$  in the directrix, is given by the equation

$$\frac{\delta \kappa}{\kappa} = - \frac{\alpha}{R_1 \theta} \frac{d\chi}{dt}.$$

If we apply dynamical methods to heterogeneous systems we shall get exactly the same equations as those we previously deduced from kinematical principles. J. J. T.

**EQUINIC ACID.** A crystalline acid said to exist in fresh mare's-milk (Duval, C. R. 82, 419).

**EQUISETIC ACID** v. **ACONITIC ACID.**

**EQUIVALENCY.** The conception of chemical equivalence is founded upon the relations between acids and bases. In the latter part of the last century some interesting and important investigations were carried on by Bergmann, Kirwan, Wenzel, and Richter on neutralisation. Their object was to determine the relative quantities of acids and bases which are necessary to effect neutralisation. Taking a certain quantity

of an acid, they attempted to determine the quantities of various bases which were necessary to neutralise this quantity of the acid; and on the other hand, taking a certain quantity of a base, they attempted to determine the quantities of various acids necessary to neutralise this quantity of the base. The important result was reached that there is a simple relation between the quantities of bases necessary to neutralise a definite quantity of an acid, and the quantities of acids necessary to neutralise a definite quantity of a base. Not long after this discovery was made, the fact that the elements combine according to a similar law, called the law of definite proportions, was discovered. This discovery, and that of the law of multiple proportions, suggested at once an enlargement of the old atomic hypothesis, and the connexion between the relative weights of the elements which enter into combination and the relative weights of the atoms was pointed out. Owing to serious difficulties in the way of determining the atomic weights, some chemists felt the necessity of getting back upon a more solid foundation than was afforded by the atomic theory in the form which it then had. It was proposed to give up the hypothesis in dealing with the proportions by weight in which the elements combine; and it was at this time that Wollaston introduced into chemistry the word equivalent. Wollaston proposed to do for the elements what some of his predecessors had done for the acids and bases. He proposed to determine the relations between the weights of the elements which combine with one another, and then to state these relations without reference to any hypothesis. The figures expressing these relations he proposed to call equivalents. The meaning of the word is simple enough. When the statement is made that 35.5 parts of chlorine are equivalent to 80 parts of bromine and 127 parts of iodine, the meaning is only that 35.5 parts of chlorine, 80 parts of bromine, and 127 parts of iodine combine with exactly the same number of parts of some other element, as, for example, with 1 part of hydrogen, 23 parts of sodium, 39.1 parts of potassium, &c. &c. The quantities named of chlorine, bromine, and iodine, are equivalent in their combining power. Clearly, figures determined in this way are independent of hypothesis.

Turning back to the acids and bases, it will be seen that the problem with which Bergmann, Richter, and others were engaged was of the same general character. In their neutralisation experiments they determined the equivalents of the acids and bases. They determined how much of a given acid is necessary to neutralise a certain quantity of a base, and how much of a second acid is necessary to neutralise the same quantity of the same base; and the quantity of the first acid was equivalent to the quantity of the second acid. So also the equivalents of the bases could be determined. Thus it is clear that the equivalent quantities of all acids on the one hand, and the equivalent quantities of all bases on the other, might be determined. By enlarging the meaning of the word equivalent, a given quantity of a base and the quantity of an acid which it can neutralise might be called equivalent.

On first thought, it would appear to be a simple matter to determine the equivalents of acids and bases; but difficulties are soon met with. We can easily determine the equivalent quantities of hydrochloric, hydrobromic, and hydriodic acids, and as each of these acids forms but one salt with a simple base, like caustic potash, the results obtained leave us in no doubt. When, however, we attempt to determine the quantity of sulphuric acid which is equivalent to 36.5 parts of hydrochloric acid, we find that the acid forms two salts with such a base as caustic potash. If we take one of these as the guide the equivalent of the acid will be one number; if we take the other salt as the guide the equivalent will be entirely different. It may be said that one of these salts has an acid reaction, and therefore, as it is obviously not neutral, it should not be taken as the guide. But if we take the case of phosphoric acid, we shall easily be misled if we depend upon the reactions of the salts to inform us which one should be used in determining the equivalent of the acid. This acid forms three salts with caustic soda. The quantities of the base necessary to form these salts are to one another as 1 to 2 to 3. As is well known, only the second salt has a neutral reaction, the third one being distinctly alkaline, and the first one acid. Why not then agree to measure the equivalents of the acids by means of those salts of the acids which contain the largest proportion of the basic constituent? That would lead us into another difficulty due to the fact that some bases have the power to form what are called basic salts, and others have not. Should we determine the equivalent of an acid by means of a base which forms basic salts, we should get one result, while if we should determine the equivalent by means of a base which does not form basic salts we should get quite a different result. Similar difficulties are encountered in attempting to determine the equivalents of the bases.

The determination of the equivalents of chlorine, bromine, and iodine is easily made. Each of these elements combines with hydrogen in only one proportion. As hydrogen has the smallest equivalent, the idea suggests itself at once of using this element as the measure of the equivalents of all the other elements. The problem would then be simply to determine the quantities of other elements which enter into combination with a fixed quantity of hydrogen, and the figures representing these quantities would bear to one another the relations of the equivalents. Using this method, it is found that the equivalent of sulphur is 16, that of nitrogen  $4\frac{1}{2}$ , that of oxygen 8, &c.

The case of carbon presents peculiar difficulties, for the reason that this element combines with hydrogen in a great many different proportions. In one of the compounds 1 part of hydrogen is combined with 3 parts of carbon, in another with 4 parts, in another with  $4\frac{1}{2}$  parts, in another with 6 parts, &c.

But most of the elements do not combine with hydrogen. In these cases how shall we determine the equivalents? It seems to be fair to use some other element, as, for example, chlorine, the equivalent of which has been determined by means of the hydrogen standard. As 35.5

parts of chlorine are equivalent to 1 part of hydrogen, it is only necessary to determine what weight of some other element combines with 35.5 parts of chlorine in order to know the equivalent of this other element. Thus 39.1 parts of potassium, 23 parts of sodium, 20 parts of calcium, and 9 parts of aluminium, combine with 35.5 parts of chlorine, and, therefore, the figures just given represent the equivalents of these elements. If chlorine is used as a measure of equivalence, then in some cases results are obtained which are different from those obtained when hydrogen is used as the measure. Thus the equivalent of phosphorus measured by hydrogen is 10 $\frac{1}{2}$ , whereas measured by chlorine it is either 10 $\frac{1}{2}$  or 6 $\frac{1}{2}$ . We may, however, agree to measure by means of chlorine the equivalents of only those elements which do not combine with hydrogen, though it would be hard to give any reason for this, except that we are led into difficulties unless the use of chlorine is thus limited. Does this end the difficulties? By no means. Iron combines with chlorine in two proportions. In one of the compounds 14 parts of iron, in the other only 9 $\frac{3}{4}$  parts of iron, are combined with 35.5 parts of chlorine. What is the equivalent of iron? If we agree to regard 14 parts of iron as equivalent to 35.5 parts of chlorine, in what light shall we regard the 9 $\frac{3}{4}$  parts which, in the other chloride, also hold in combination 35.5 parts of chlorine? Are these also equivalent to 35.5 parts of chlorine? If so, then plainly we are led to the startling conclusion that 14 parts of iron are equivalent to 9 $\frac{3}{4}$  parts of iron.

It appears that any attempt to determine the equivalents of the elements without reference to some hypothesis must end in failure, or at least it must lead to unsatisfactory results. There is so much room for doubt in regard to which figure to select as the equivalent that, in many cases, two, and even more than two, equivalents might with equal right be selected by different investigators. Plainly, the solid foundation which Wollaston desired, and which we all desire, is not furnished by a system of equivalents. In dealing with similar elements and similar compounds we can speak of equivalent quantities without danger of confusion. Thus, for example, we cannot be misunderstood in speaking of equivalent quantities of chlorine, bromine, and iodine; of nitric acid and hydrochloric acid; of sulphuric acid and sulphurous acid. At present, however, the word equivalent is used very much less than it was in the early part of this century, for the reason that other and clearer conceptions have been introduced into the science. What relation the equivalent bears to the later conceptions will be shown further on.

For the cases named above, and for similar cases in which an element combines with another in more than one proportion, it may be assumed that in one compound a certain number of equivalents of the one element are in combination with one equivalent of the other element, while in the second compound another number of equivalents of the second element are in combination. Thus, in water, 8 parts of oxygen are in combination with 1 part of hydrogen, while in hydrogen dioxide 16 parts of oxygen are in combination with 1 part of hydrogen. It may

be assumed that in water one equivalent of oxygen is combined with 1 equivalent of hydrogen, while in hydrogen dioxide 2 equivalents of oxygen are in combination with 1 equivalent of hydrogen. In this case, what is an equivalent? How can we properly speak of 2 equivalents of one element combining, with 1 equivalent of another? In doing so we unconsciously make use of an hypothesis, and, if we attempt to express this hypothesis in words clearly, we shall certainly find that it is essentially the atomic hypothesis of Dalton, according to which the combination of elements takes place between small particles which have definite weights. Call these weights equivalents, combining weights, or atomic weights, the hypothesis is essentially the same. The moment we accept such an hypothesis the problem of determining equivalents in the new sense becomes the determination of the relative weights of the smallest particles of the elements which enter into chemical combination. To these new weights the term equivalent is not applicable. It may, however, be retained in its old sense, while the name atomic or combining weight is applied to the smallest weight of an element which enters into chemical combination. This atomic weight may or may not be identical with the equivalent.

To make this clear we may consider the case of nitrogen. As we have seen, the equivalent of nitrogen, deduced from a consideration of the composition of ammonia, is  $4\frac{1}{2}$ . On studying the compounds of nitrogen carefully we soon find that the quantity of nitrogen found in these is generally considerably larger than is represented by the figure  $4\frac{1}{2}$ . Thus in nitric acid 1 part of hydrogen there are 14 ( $= 3 \times 4\frac{1}{2}$ ) parts of nitrogen; and when ammonia enters into combination with other substances, as with hydrochloric and nitric acids, the quantity which thus combines is three times as great as that which is represented by one equivalent ( $4\frac{1}{2}$  parts) of nitrogen and one equivalent (1 part) of hydrogen. Or, instead of  $5\frac{1}{2}$  parts of ammonia being the smallest weight of the substance which enters into combination, this smallest weight is 3 times  $5\frac{1}{2}$  parts or 17 parts. When ammonia acts upon hydrochloric acid, for example, 86.5 parts of the acid combine with 17 parts of ammonia, and not with  $5\frac{1}{2}$  parts. Similar observations are made in the cases of all compounds of ammonia. Further, a study of certain changes which can be effected in ammonia shows clearly that the hydrogen contained in the substance can be taken out one-third at a time in three stages, and other things put in its place, thus proving that in the smallest particle of ammonia there must be contained at least three smallest particles of hydrogen. The nitrogen cannot, however, be thus displaced in parts. If it leaves the compound at all, all of it leaves at once. Taking, then, all our knowledge together, it appears that the smallest particle of nitrogen which enters into chemical combination is 14 times heavier than the smallest particles of hydrogen, and that in ammonia one of these particles of nitrogen is in combination with three of the smallest particles of hydrogen. We therefore call 14 the combining weight, or, now, accepting the hypothesis, the atomic weight, of nitrogen. But the equivalent of nitrogen is not changed by this; the equivalent remains  $4\frac{1}{2}$ .

The atomic weight is three times as great as the equivalent.

The case of carbon is also instructive. Taking marsh gas it appears that the equivalent of carbon is 3, as in this compound 3 parts of carbon are combined with 1 part of hydrogen. But the hydrogen of marsh gas can be easily displaced by other elements, and four distinct steps in the reaction can be recognised. In each step one-fourth of the hydrogen is displaced. In all the reactions of marsh gas a quantity takes part which contains 12 parts of carbon and 4 parts of hydrogen. Further, an extensive study of carbon compounds has shown that the smallest particle of this element which enters into chemical action is twelve times as great as the smallest particle of hydrogen found in combination. Therefore, we say the atomic weight of carbon is 12. But the equivalent of carbon as deduced from the analysis of marsh gas is 3. The atomic weight is four times as great as the equivalent. Similar studies of oxygen compounds have shown that the atomic weight of oxygen is 16, while its equivalent is 8, or the ratio of equivalent to the atomic weight is 1:2. On the other hand, the atomic weights of chlorine, bromine, and iodine are 35.5, 80, and 127 respectively, and these are also the equivalents; so that while, in the case of carbon, the ratio of the equivalent to the atomic weight is 1:4, in the case of nitrogen 1:3, and in the case of oxygen 1:2; in that of chlorine, bromine, and iodine it is 1:1. This suggests that there is some fundamental difference between chlorine, oxygen, nitrogen, and carbon, which is not taken into consideration in the atomic hypothesis of Dalton. Study of other elements besides those mentioned shows that they may be divided into classes according to the ratio between the equivalent and the atomic weight. This ratio varies from 1:1 to 1:6.

It has already been pointed out that the determination of the equivalents of the elements is a difficult problem. The determination of atomic weights by chemical means alone is also a difficult matter. Although by analysing chemical compounds and studying the chemical changes which these compounds undergo, we can draw conclusions as to the atomic weights of some of the elements, yet as to others we should be left in doubt if assistance were not furnished by a study of some of the physical properties of the compounds. In the article on ATOMIC AND MOLECULAR WEIGHTS (vol. i. p. 336) the application of Avogadro's hypothesis, and of the law of Dulong and Petit regarding the specific heat of the elements, to the problem of determining atomic weights, has been discussed. It is an important fact that the atomic weights determined by the physical methods are in most cases those which experience has shown to be best adapted to the interpretation of known chemical reactions. Not only does Avogadro's hypothesis give us a method for determining atomic weights, but primarily it leads us to definite values for molecular weights. By determining the molecular weights and analysing the compounds, and thus determining the atomic weights, we are led to definite conceptions regarding the composition of the molecules of compounds and of elements. At present we endeavour to express the composition of molecules by our formulae.

There are now three conceptions to be distinguished carefully from one another. These are the *molecule*, the *atom*, and the *equivalent*. By the molecule is meant the smallest gaseous particle of a substance, whether elementary or compound, which exhibits the characteristic properties of the substance; by the atom is meant the smallest particle of an element which enters into the composition of molecules. The basis upon which the conceptions of molecule and atom rest is considered more fully in the article on ATOMIC AND MOLECULAR WEIGHTS.

With these conceptions clearly in mind we may now ask, what is the equivalent of an element? It is that mass of the element which combines with one atom of hydrogen. In the case of oxygen it corresponds to half the atom, in that of nitrogen to one-third the atom, and in that of carbon to one-fourth the atom. With those elements which do not combine with hydrogen some other element like hydrogen in respect to the ratio between the equivalent and atomic weight is taken as the measure of the equivalent. The results reached in this way have already been referred to.

While those investigations were in progress which finally led to the clear recognition of the difference between atoms and molecules, chemists came to recognise resemblances between different classes of compounds, and it was finally suggested that all compounds are related to a few simple ones, which may be regarded as types. For example, hydrochloric acid,  $\text{HCl}$ , hydrobromic acid,  $\text{HBr}$ , and hydriodic acid,  $\text{HI}$ , are similar compounds and they have a similar composition. Of such compounds, hydrochloric acid,  $\text{HCl}$ , may be taken as the type. Water  $\text{H}_2\text{O}$ , hydrogen sulphide  $\text{H}_2\text{S}$ , and other compounds belong to the water type. Ammonia  $\text{NH}_3$ , phosphine  $\text{PH}_3$ , arsine  $\text{AsH}_3$ , belong to the ammonia type. Marsh gas  $\text{CH}_4$ , silicon hydride  $\text{SiH}_4$ , belong to the marsh-gas type. This classification of compounds according to the type was extended so as to include most compounds, even those which are complex. Serious difficulties were met with in many cases. In some, the difficulty was due mainly to the fact that one and the same compound could belong at the same time to two or more types. This led to the introduction of mixed types. In other cases the difficulty was due to the fact that the reactions of the substance gave little or no clue to its type. In such cases the imagination was freely brought into play with highly unsatisfactory results. Notwithstanding the difficulties which were encountered in the attempt to classify compounds according to types, the attempt led to valuable results. It led to a clearer recognition of differences between molecules, differences which are as real as the molecules themselves. The recognition of these differences does not, however, carry with it any explanation. For to say that each of these compounds belongs to a certain type is not even to attempt an explanation. It is simply the statement of what appears to be a fact. We might determine with certainty to which type or types every known chemical compound belongs, and yet be no nearer an understanding of the differences between the compounds than before the determination. This was first clearly seen by Kekulé,

who showed that, in order to understand the relations which exist between the various chemical compounds, it is necessary to go back to the atoms themselves, and inquire what relations they bear to one another in the molecules. The cause of the difference between hydrochloric acid, water, ammonia, and marsh gas, is to be looked for in the atoms of chlorine, oxygen, nitrogen, and carbon. Obviously the first conclusion that forces itself upon us is that the atoms of different elements differ with respect to the number of hydrogen atoms with which they can combine to form compound molecules. While one atom of chlorine combines with only one atom of hydrogen, one atom of oxygen combines with two atoms of hydrogen, one atom of nitrogen combines with three atoms of hydrogen, and one atom of carbon combines with four atoms of hydrogen. Having recognised this difference, the question suggests itself whether an atom of chlorine can hold more than one atom of hydrogen in combination; further, whether an atom of oxygen can combine with a larger or smaller number of hydrogen atoms than two; and similar questions arise with reference to nitrogen and carbon. How far, in other words, are the differences which we have observed fixed and invariable? These questions can be answered only by carefully studying the compounds of the elements named. There is only one compound of hydrogen and chlorine. It therefore appears that one atom of chlorine can hold but one atom of hydrogen in combination, and similarly one atom of hydrogen can hold but one atom of chlorine in combination. Oxygen and hydrogen, however, combine in two different proportions forming the compounds  $\text{H}_2\text{O}$  and  $\text{H}_2\text{O}_2$ ; while in water it appears that one atom of oxygen holds two atoms of hydrogen in combination, in hydrogen dioxide it appears that two atoms of oxygen hold two atoms of hydrogen.<sup>1</sup> Nitrogen and hydrogen form but one compound with each other. Carbon and hydrogen on the other hand form a large number of compounds with each other. Of these only one contains a single atom of carbon in the molecule. That is marsh gas, and in the molecule of this compound there are four hydrogen atoms to the atom of carbon. There are three compounds of these elements in whose molecules there are two atoms of carbon. They are  $\text{C}_2\text{H}_2$ ,  $\text{C}_2\text{H}_4$ , and  $\text{C}_2\text{H}_6$ . Before attempting to explain this let us see what general conclusion is justified by the facts above recorded. What is true of the relations of chlorine and hydrogen is equally true of bromine and hydrogen, and of iodine and hydrogen. What is true of oxygen and hydrogen is true of sulphur, selenium, and tellurium, and hydrogen. What is true of nitrogen and hydrogen is true of phosphorus, arsenic, and antimony, and hydrogen. And, finally, what is true of carbon and hydrogen, so far as their relations in marsh gas are concerned, is also true of silicon and hydrogen. We are therefore justified in making the statement that the atoms of different elements differ from one another with reference to the number of atoms of hydrogen they can

<sup>1</sup> But it is to be observed that as hydrogen peroxide has not been gasified, the formula  $\text{H}_2\text{O}_2$  does not necessarily represent the atomic composition of the molecule of this compound.—M. M. F. M.

combine with to form compound molecules. As regards formation of molecules, the atoms of the elements can be divided into at least four classes:—

1. Those which combine with hydrogen in the simplest proportion of one atom to one atom of hydrogen.
2. Those which combine with hydrogen in the proportion of one atom to two atoms of hydrogen.
3. Those which combine with hydrogen in the proportion of one atom to three atoms of hydrogen; and
4. Those which combine with hydrogen in the proportion of one atom to four atoms of hydrogen.

Our conception of the chemical atom is thus enlarged. It is not only a minute particle of matter, which in chemical changes is not broken up, and which has a definite mass, and the power of combining with other atoms, but it also has some power which determines how many atoms of another kind it can combine with. At present we cannot form a clear conception as to the cause of this power, and no hypothesis has as yet been proposed to account for it. We can represent the fact by means of symbols, but these symbols do not help us to understand the cause, though they are convenient. We may also adopt figurative forms of expression suggested by our symbols, but this has not as yet advanced our knowledge of the cause of the property of the atoms with which we are dealing.

On examining the composition of the molecules of the compounds which any element forms with other elements than hydrogen, we find that just as the number of hydrogen atoms with which one atom of the element can combine is limited so the number of atoms of other elements with which it can combine is limited. Thus phosphorus combines with chlorine to form the compounds  $\text{PCl}_3$  and  $\text{PCl}_5$ , with hydrogen to form the compounds  $\text{PH}_3$  and  $\text{P}_2\text{H}_4$ , and with oxygen to form the compounds  $\text{P}_2\text{O}_3$  and  $\text{P}_2\text{O}_5$ . Sulphur combines with hydrogen to form the compounds  $\text{SH}_2$  and probably  $\text{S}_2\text{H}_2$ , with chlorine to form the compounds  $\text{S}_2\text{Cl}_2$ ,  $\text{SCl}_2$  and  $\text{SCl}_4$ , and with oxygen to form  $\text{SO}_2$  and  $\text{SO}_3$ , &c., &c. From facts like these we conclude that atoms are so constructed, or act in such ways, that the number of other atoms with which each can combine is limited, and that as regards the number of other atoms with which they can combine, they differ from one another.

The property of an atom which determines the number of other atoms with which it can combine to form a compound molecule is called its *valency*. The relation between the atomic weight of an element, its equivalent, and its valency, will readily be understood by the aid of a few examples. The atomic weight of nitrogen, as determined by chemical and physical methods, is 14; its hydrogen-equivalent is  $\frac{14}{4}$ , as this is the relative weight of nitrogen which combines with one part by weight of hydrogen. The number of atoms of hydrogen with which the atom of nitrogen combines is 8 or  $\frac{14}{\frac{14}{4}}$  (at. wt.). So also in the case of carbon. The atomic weight of carbon is 12, its

hydrogen-equivalent is 3; the number of hydrogen atoms with which an atom of carbon can combine is  $\frac{12}{3}$  (at. wt.) = 4, &c. In general, the

number of hydrogen atoms with which the atom of any element can combine is expressed by a figure which also expresses the relation between the atomic weight and the hydrogen equivalent of the element.

The recognition of the property called valency proved of the highest importance for chemistry. Discussions in regard to this property have now been carried on for nearly thirty years, and our views in regard to the structure of chemical compounds are based upon it. It is, therefore, desirable to study it with some care, with the object of determining exactly what is known in regard to it, so that we may be in a position, on the one hand, to recognise its value, and, on the other hand, to avoid the dangers to which we are exposed in following the conception blindly.

Before the introduction of the conception of valency, each chemical compound was looked upon as a whole. To be sure, the difference between atoms and molecules, first pointed out by Avogadro, gradually came to be recognised, and in a general way it was acknowledged that the molecule is made up of atoms. But, beyond this, inquiry was not pushed to any extent. This is shown in an instructive way by a study of the investigations of Hofmann, Wurtz, and others, on the so-called substituted ammonias. When Hofmann began his investigations on aniline, the prevailing view in regard to this compound was that it was a conjugated compound (*gepaarte Verbindung*); that it contained ammonia combined with a hydrocarbon. Using the modern atomic weights, the view referred to is expressed by the formula  $\text{C}_6\text{H}_5\text{NH}_2$ . The common reactions of aniline were interpreted by supposing that the group  $\text{C}_6\text{H}_5$  simply accompanied the ammonia. Some time before this Liebig had suggested that certain bases like aniline might be regarded as containing the group  $\text{NH}_2$ . According to this 'amide theory' of Liebig, aniline is to be represented by the formula  $\text{C}_6\text{H}_5\text{NH}_2$ . In this compound, then, ammonia as such is not supposed to be present, but, nevertheless, there is in it a remnant of ammonia which gives to the compound certain of the characteristic properties of ammonia. Wurtz discovered the bases methylamine and ethylamine at the time that Hofmann was engaged in his studies on aniline, and at about the same time each suggested that the substances he was working with might be regarded as ammonia in which one of the hydrogen atoms is replaced by a radicle. Before Hofmann closed his work on aniline he furnished strong experimental evidence against the theory of conjugated compounds as far at least as it applies to aniline. He showed that the reactions between ammonium oxalate and phosphoric anhydride are not the same as those between aniline oxalate and phosphoric anhydride, and that the difference cannot be understood if aniline be regarded as a conjugated compound, but that it is easily explained if aniline be regarded as ammonia in which one hydrogen has been replaced by the hydrocarbon residue  $\text{C}_6\text{H}_5$ . The subsequent preparation of substituted ammonias in which two and three

hydrogen atoms of ammonia were replaced by radicles, and of compounds derived from ammonium by the replacement of all the hydrogen atoms, furnished a solid foundation for the view put forward in the so-called theory of types. As has already been stated, according to the theory of types every compound is built according to some plan, and the number of plans according to which compounds are built is small, the fundamental plans or types being hydrogen  $\text{IH}$ , hydrochloric acid  $\text{HCl}$ , water  $\text{H}_2\text{O}$ , and ammonia  $\text{H}_3\text{N}$ . Much attention was now given to determining the type to which any given compound belonged, and when, after investigation of the properties and composition of a compound, a definite statement regarding the type to which it belonged could be made, the problem was considered to be solved. No further questions were asked. It was as if one should look alone at the exterior of buildings, and compare them solely with reference to the exterior, without making any inquiry with regard to the interior arrangements, the connexions between the rooms, &c.

Shortly after Hofmann's papers appeared, an important paper by E. Frankland was published (1852). The author had been investigating a new class of compounds containing metals. At the close of the paper, the chemical structure of the compounds is discussed. Attention is called to the fact that when a metal has combined with a hydrocarbon, as in the case of tin ethyl,  $\text{SnC}_2\text{H}_5$ , (using old formulae), the power of the metal to combine with other elements, as oxygen, is not so great as that of the uncombined metal. While tin alone combines with oxygen in two proportions, forming the compounds  $\text{SnO}$  and  $\text{SnO}_2$ , tin-ethyl  $\text{SnC}_2\text{H}_5$  combines with oxygen in only one proportion, forming the compound  $\text{SnC}_2\text{H}_5\text{O}$ , and this compound cannot take up any more oxygen even when boiled with dilute nitric acid. Similar observations were made with reference to the corresponding derivatives of antimony and arsenic. In commenting further upon these remarkable facts, the author shows that they are directly opposed to the theory of conjugated compounds, according to which the compounds under consideration are regarded as containing the unchanged metals conjugated with hydrocarbons. He then says: 'When the formulae of inorganic chemical compounds are considered, even a superficial observer is struck with the general symmetry of their construction; the compounds of nitrogen, phosphorus, antimony, and arsenic especially exhibit the tendency of these elements to form compounds containing 3 or 5 equivalents of other elements, and it is in these proportions that their affinities are best satisfied; thus in the ternary group we have  $\text{NO}_2$ ,  $\text{NH}_3$ ,  $\text{NI}_3$ ,  $\text{NS}_3$ ,  $\text{PO}_3$ ,  $\text{PH}_3$ ,  $\text{PCl}_3$ ,  $\text{SbO}_3$ ,  $\text{SbH}_3$ ,  $\text{SbCl}_3$ ,  $\text{AsO}_3$ ,  $\text{AsH}_3$ ,  $\text{AsCl}_3$ , &c., and in the five-atom group  $\text{NO}_5$ ,  $\text{NH}_5\text{O}$ ,  $\text{NH}_5\text{I}$ ,  $\text{PO}_5$ ,  $\text{PH}_5\text{I}$ , &c. Without offering any hypothesis regarding the cause of this symmetrical grouping of atoms, it is sufficiently evident, from the examples just given, that such a tendency or law prevails, and that, no matter what the character of the uniting atoms may be, the combining power of the attracting element, if I may be allowed the term, is always satisfied by the same number of these atoms' (*Philosophical Transactions*, 1852, p. 440).

Thus the conception of the saturation of atoms was introduced into chemistry. It was soon taken up by others, as Williamson and Odling, and finally, at about the same time in 1858, Kekulé and Cooper showed how this conception might be applied to the explanation of the constitution of chemical compounds in general. Kekulé took up the problem in a broad way, and it is largely due to his efforts that the conception of valency became the controlling conception in the discussions in regard to the structure of chemical compounds. Kekulé says: 'I consider it necessary, and, in the present condition of chemical knowledge, in many cases possible, in the explanation of the properties of chemical compounds, to go back to the elements themselves which make up the compounds. I do not consider the chief task of investigation to be the detection of groups of atoms which on account of certain properties are to be regarded as radicles, and thus to refer the compounds to a few types which are scarcely more than sample formulæ. I believe rather that investigation may include the radicles themselves, and point out the relations between the radicles, and that, from the nature of the elements, the nature of the radicles and of the compounds can be deduced.'

In the valencies of the atoms we now find the explanation of types. The reason why most compounds are to be compared with hydrochloric acid, water, ammonia, and marsh gas, is that the atoms of most elements are like chlorine oxygen, nitrogen, or carbon in respect to the number of atoms of other elements with which they can combine. The simplest kind of atom is one like that of chlorine or hydrogen; next come those which are like those of oxygen. The chlorine atom can hold in combination but one atom of hydrogen: the oxygen atom has twice this power, it can hold two atoms of hydrogen in combination; the nitrogen atom can hold three atoms of hydrogen in combination; and finally the carbon atom can hold in combination four atoms of hydrogen. Chlorine, oxygen, nitrogen, and carbon represent these four different kinds of elements.

Chlorine is called a *monovalent* element, because its atom combines with but one atom of hydrogen to form a compound molecule; oxygen is called a *divalent* element, nitrogen a *trivalent* and carbon a *tetravalent* element. Further, the elements are called respectively *monads*, *dyads*, *triads*, *tetrads*, *pentads*, *hexads*, &c.

From what has been said it will be clear the valency is something quite different from affinity. By affinity is commonly meant the unknown cause of the combination of atoms. Hydrogen and chlorine combine very readily; they have as we say, a strong affinity for each other; yet they are monovalent with reference to each other. Carbon and chlorine do not combine readily they have not a strong affinity for each other yet carbon is tetravalent towards chlorine, its atom is capable of holding four atoms of carbon in combination. The two properties valency and affinity are possessed by every atom, and exhibit themselves whenever atoms act upon or another, the latter determining the intensity of the reaction, the former the complexity of the resulting molecule.

In this discussion thus far the valency of an element has been measured by considering the number of atoms of hydrogen with which its atom can combine to form a compound molecule. It is, however, a fair question whether the valency of an element towards other elements is necessarily the same as towards hydrogen. Is it fair to conclude that, because an element is trivalent towards hydrogen, it is also trivalent towards chlorine and other elements? As we have yet no conception in regard to the cause of the property which we call valency, we have not a right to make assumptions of this kind. The only way to answer the question is to study the facts. For this purpose let us take the case of carbon. This element is tetravalent towards hydrogen. Towards chlorine it is also tetravalent, as is shown by the molecule  $\text{CCl}_4$ . Towards oxygen it appears to be tetravalent in carbon dioxide,  $\text{CO}_2$ , in which we have the atom of carbon in combination with two divalent atoms of oxygen. But in carbon monoxide,  $\text{CO}$ , either carbon acts as a divalent element or oxygen acts as a tetravalent element. Towards sulphur carbon is tetravalent, as shown in carbon disulphide,  $\text{CS}_2$ , in which one atom of carbon holds in combination two divalent atoms of sulphur. Phosphorus is trivalent towards hydrogen, it cannot form a compound with hydrogen containing a larger number of atoms of hydrogen than three. It is, however, pentavalent towards chlorine, as shown in the compound phosphorus pentachloride,  $\text{PCl}_5$ , and it is also trivalent towards this element, as shown in the trichloride  $\text{PCl}_3$ . Phosphorus also combines with oxygen in two proportions, forming the trioxide,  $\text{P}_2\text{O}_3$ , and the pentoxide,  $\text{P}_2\text{O}_5$ , and the compositions of these can be best explained by assuming that, in the former, the phosphorus is trivalent, and, in the latter, pentavalent. Sulphur is divalent towards hydrogen, forming the compound  $\text{SH}_2$ . With chlorine it forms the compounds  $\text{S}_2\text{Cl}_2$ ,  $\text{SCl}_2$ , and  $\text{SCl}_4$ . With oxygen it forms the compounds  $\text{SO}_2$  and  $\text{SO}_3$ , in which the sulphur appears to be tetravalent and hexavalent. Iodine is monovalent towards hydrogen, but towards chlorine it acts both as a monovalent and as a trivalent element, as shown in the compounds  $\text{ICl}$  and  $\text{ICl}_3$ . Nitrogen, which is only trivalent towards hydrogen, appears to be pentavalent in the compound  $\text{NH}_4\text{Cl}$  and other similar ammonium compounds. With oxygen it combines in a number of proportions, as is well known.<sup>1</sup>

The simplest interpretation of the facts just stated is that the valency of an element towards hydrogen is not necessarily its valency towards other elements, and that the valency of one element towards another may be one thing in one compound and different in another compound. Although this is the simplest interpretation, it does not follow that it is the correct one. It is possible that the valency of an element is always the same, but that, owing to the surrounding conditions and the character of the element with

which it combines, the full valency is not always exhibited. Until we have a clear conception in regard to the cause of valency, or until we have a satisfactory hypothesis of valency, discussions on the question whether valency is constant or variable must be more or less idle. If valency be something inherent in the atom, like the mass of the atom, then it is impossible to conceive of it as being variable. If, however, it be a condition of the atom; if, for example, it is dependent on the motion of the atom, then, as the motion may differ under different circumstances, the valency also may differ.

It is not uncommon to think of atoms as joined together in some such way as small objects adhere to one another under the influence of electric or magnetic attraction. It is supposed that the monovalent atom has but one place where another atom can be attached, or that it has but one pole, or that there is but one direction in which another atom can enter into combination with it. These phrases do not help us much, and they do not differ materially from one another. If such a view is held, it carries with it, of course, a similar view in regard to divalent, trivalent, and, in general, polyvalent, atoms. Each atom has a number of places where other atoms can be attached, the number corresponding to the valency of the atom. The graphic symbols so commonly used to represent the structure of chemical compounds in terms of the conception of valency are well calculated to give the idea that the view just stated is generally accepted. Of course, if it is accepted, valency is considered as a constant property. In this case it will be necessary to furnish explanations of those compounds which seem to prove that valency is variable. Some of the explanations which have been offered will now be considered.

Among the compounds which appear to show that valency is variable is the well-known series of oxygen compounds of chlorine and of nitrogen. While chlorine forms only one compound with hydrogen, and is unquestionably monovalent towards hydrogen, it appears to have a greater valency towards oxygen. This is explained by some by assuming that in those compounds of chlorine and oxygen in which there is more than one atom of oxygen in the molecule the oxygen atoms are combined with each other as represented in the formulae  $\text{Cl}-\text{O}-\text{O}-\text{Cl}$  and  $\text{Cl}-\text{O}-\text{O}-\text{O}-\text{Cl}$ , in which the chlorine is represented as monovalent and the oxygen as divalent. To explain the existence of the series of oxides of nitrogen, on the assumption that the valency of oxygen is always two and that of nitrogen three, a similar method is used; if necessary, combination is assumed between nitrogen atoms, between oxygen atoms, and between nitrogen and oxygen atoms. But even with these possibilities all these compounds cannot be explained without the aid of a new conception. It is assumed that a polyvalent element may be in combination with itself in more than one way. Just as hydrogen in the hydrogen molecule must be assumed to be in combination with itself in the same way that it is in combination with chlorine in the molecule of hydrochloric acid, so oxygen must be in combination with itself in the molecule of oxygen. But oxygen

<sup>1</sup> It is important to note that many of the compounds cited above have not been gasified, and that therefore the formulae given are not all molecular; it is known that some of the compounds, e.g.  $\text{PCl}_5$  and  $\text{NH}_4\text{Cl}$ , are dissociated by heat. It is doubtful whether arguments regarding the valencies of atoms should be based on the compositions of any compounds except those which have been gasified; as it is only to gases that the conception of the theory of atoms and molecules can, at present, be strictly applied.—M. M. P. M.

is divalent; i.e., on the present hypothesis, its atom has two places where combination with other atoms can be effected. To express the conception that both these places are occupied in the molecule of oxygen, this molecule is represented graphically thus  $O=O$ , while the molecule of hydrogen is represented thus  $H-H$ . The latter condition is spoken of as single union, the former as double union. So, too, triple union is supposed to exist in the molecule of nitrogen as represented thus  $N\equiv N$ . Now, in explaining the oxides of nitrogen it is assumed that in some cases the nitrogen atoms are in combination by single union, and in others by double union. Thus nitrous oxide  $N_2O$  is represented in this

way  $\begin{array}{c} N \\ \diagup \quad \diagdown \\ O \end{array}$ ; the trioxide thus  $\begin{array}{c} N-O \\ \diagup \quad \diagdown \\ N-O \end{array} O$ . The

compounds  $NO$  and  $NO_2$  plainly cannot be explained in this way. For these a new assumption, which will be considered later, must be made. The tetroxide  $N_2O_4$  may be represented

in this way  $\begin{array}{c} N-O-O \\ | \quad | \\ N-O-O \end{array}$ .

The question will now suggest itself, have we any evidence that the structural formulae above given are correct? Is there any experimental evidence in favour of them? The answer is that we have no evidence whatever in favour of them, and the only reason for accepting them is that they are in accordance with the indefinite and crude view in regard to the nature of valency above referred to. The argument is this: valency must be a constant property of elementary atoms; but nitrogen is trivalent and oxygen is divalent; therefore the compounds of these elements must be constituted in the way represented. It must, however, be distinctly borne in mind that for some of the compounds there are other formulae, besides those given above, which answer the requirements, and which are just as probable. For example, nitrogen trioxide

may be represented thus  $O \begin{array}{c} N-O \\ | \quad | \\ N-O \end{array}$ ; and the to-

trioxide thus  $O \begin{array}{c} N-O \\ | \quad | \\ N-O \end{array} O$ , or thus  $\begin{array}{c} O-N-O \\ | \quad | \quad | \\ O-N-O \end{array}$ .

In explaining the existence of the two series of compounds of mercury, copper, iron, aluminium, &c., the same method is commonly adopted. Mercury and copper are regarded as divalent in both series of compounds, and the structure of the compounds is represented thus: mercuric compounds  $Hg \begin{array}{c} Cl \\ | \\ Cl \end{array}$ ,  $Hg=O$ ; cupric compounds

$Cu \begin{array}{c} Cl \\ | \\ Cl \end{array}$  and  $Cu=O$ ; mercurous\* compounds

$Hg-Cl \quad Hg \begin{array}{c} Cl \\ | \\ Cl \end{array} O$ ; cuprous compounds  $Cu-Cl$

$Hg-Cl \quad Hg \begin{array}{c} Cl \\ | \\ Cl \end{array} O$  and  $\begin{array}{c} Cu \\ | \\ Cu \end{array} O$ .

There are many cases which cannot be explained by any of the assumptions thus far referred to. As good an example as any is that of the two chlorides of phosphorus,  $PCl_3$  and  $PCl_5$ . Here, plainly, phosphorus is in combination with chlorine in more than one proportion,

and this cannot be explained by assuming that in one of these compounds two atoms of phosphorus are in combination with each other, for the molecular weights of the chlorides are properly represented by the above formulae. It has been suggested by Kekulé that the pentachloride is not a true chemical compound, but that it is made up of a molecule of phosphorus trichloride and a molecule of chlorine held in combination by some force different in character from that which holds the atoms together in a molecule. This conception may be represented thus  $PCl_3 \cdot Cl_2$ . The fact that when the compound is heated it readily breaks down, forming the trichloride and free chlorine, was regarded by Kekulé as evidence in favour of the view which he put forward. He called compounds of this kind 'molecular compounds,' to distinguish them from true chemical compounds or atomic compounds. He considered them to be similar to salts with water of crystallisation, from which the water is given off by heat.

One serious objection to this view is that many of the cases which it was invented to explain cannot be explained by it. While it is true that phosphorus pentachloride does break down under the influence of heat, the analogous pentafluoride is stable, and there is no reason for assuming that it differs from other chemical compounds. Then, too, it has been shown that the pentachloride itself can be converted into vapour in the presence of the vapour of the trichloride. At present this hypothesis of molecular compounds does not play an important part in dealing with the subject of valency.<sup>1</sup>

A more satisfactory suggestion which has been made with reference to the variations in valency is that while an atom may have a constant maximum valency, its entire valency may not be exhibited in certain compounds. Those compounds of an element in which its full valency is brought into play are called *saturated compounds*, and those in which the full effect of the valency is not shown are called *unsaturated compounds*. Thus, according to this view, phosphorus is pentavalent, and in the pentachloride, which is a saturated compound, its full valency is brought into play, while in the trichloride only a part of its valency is brought into play, the compound being unsaturated. The difference between carbon monoxide  $CO$  and the dioxide  $CO_2$  is accounted for in the same way. The expressions 'its full valency is brought into play' and 'only a part of its valency is brought into play' cannot at present be further explained, but this is not a sufficient reason for refusing to use them. The facts show clearly that the manifestation of that power which we call valency is subject to variations. We must use some expressions to state these facts. The chief objection to the expressions is that they suggest the idea of parts of an atom acting differently, or of some parts of an atom being brought into action while other parts are not acting, an idea which is not only improbable, but absurd. But this idea is not necessarily involved in the conception of saturated and unsaturated atoms. Thus carbon has the power

<sup>1</sup> This is especially true if we agree to restrict our conceptions of valency to the consideration of gaseous molecules.—M. M. P. M.

to combine with oxygen in the proportions indicated by the formula  $\text{CO}$  and  $\text{CO}_2$ . It is certain that the carbon atom in the monoxide has the power to take up more oxygen, and that when more oxygen is presented to it under the right conditions the additional oxygen is taken up. Because the monoxide can take up as much oxygen as it already contains, it does not follow that the carbon atom in the monoxide is only half employed, any more than it follows that, because a magnet which can support two pounds is supporting only one pound, it is therefore only half employed. The whole magnet acts in both cases: in the one case it is saturated, in the other it is unsaturated. There is, however, this marked difference between the case of the magnet and that of the atom. In the former any weight, from the lightest to that necessary for saturation, can be held in combination, whereas in the latter the variations are determined by the weights of the atoms which are held in combination. Although then it is most probable that in every chemical compound, whether saturated or unsaturated, every atom is brought into action in every part, it appears probable that the atoms can adjust themselves in different ways with reference to one another.

Some investigations have been undertaken with the object of throwing light upon the question whether different parts of an atom can act differently. To illustrate the methods the case of carbon may be taken. The carbon atom is tetravalent. It combines with four atoms of hydrogen, chlorine, &c., to form compound molecules. Are all the four atoms which it holds in combination held with the same force? The facts appear to give an affirmative answer. If the atoms were held in different ways, then it should be possible to make more than one compound of the formula  $\text{CH}_4\text{Cl}_4$ , or any other mono-substitution product of marsh gas. But, as a matter of fact, only one variety of these mono-substitution products has ever been prepared. Then, further, the theory in regard to the structure of the hydrocarbons of the paraffin series is based upon the assumption that each of the four hydrogen atoms in marsh gas is held in exactly the same way by the carbon atom; and this assumption is so perfectly in accordance with a large number of facts that it is worthy of the most serious consideration as an argument. There is one experiment which appears to show that in the case of sulphur the four affinities, as the hypothetical individual points of attraction, or the parts into which the total valency may be divided, are called, are not exactly the same. Krüger asserts that the product of the combination of  $(\text{C}_2\text{H}_5)_2\text{S}$  and  $\text{CH}_3\text{I}$  is different from the product formed by combining  $\text{S}(\text{CH}_3)(\text{C}_2\text{H}_5)$  with  $\text{C}_2\text{H}_5\text{I}$ ; yet both compounds are represented by the formula  $\text{SEt.MeI}$ . If it is assumed that in these compounds the sulphur is tetravalent, then it appears to follow that the four affinities of the sulphur atom are not identical in value; because if it were immaterial in what way the groups Et and Me, and the atom I, were arranged relatively to the S atom with which all are in direct union, then only one compound  $\text{SEt.MeI}$  could exist. A similar conclusion seems

\* Recent research has invalidated Krüger's results.

to be justified in the case of nitrogen, as shown by Lossen's investigations on derivatives of hydroxylamine. Lossen showed that when two different radicles are introduced into hydroxylamine in place of hydrogen, a large number of isomeric substances are obtained instead of one, as we should expect. The case of nitrogen has been investigated by V. Meyer and by Ladenburg, but the results obtained by these two investigators differ. Taking all the evidence into consideration it appears that by far the larger number of facts of chemistry clearly indicate that the affinities of an atom are of the same kind, while in the case of sulphur and of nitrogen the facts referred to require further investigation.

It is sometimes held that, because a certain number of atoms are readily given off from a molecule of a compound, there are weaker and stronger affinities. Thus, when phosphorus pentachloride is heated it gives up two atoms of chlorine. From this the conclusion is sometimes drawn that in phosphorus pentachloride three of the atoms of chlorine are held in combination more firmly than the other two. Such a conclusion is, however, evidently unjustified. All that we can say is, that at the higher temperature the more complex compound cannot exist, while the trichloride can. It is probable that in the trichloride the whole of the phosphorus atom is employed in holding the three chlorine atoms in combination, and that this is also true of the phosphorus atom and the five chlorine atoms in the pentachloride. If this is true, then it follows that the pentachloride must be a less stable compound than the trichloride.

Whatever method of explaining the variations in the composition of the compounds of any elements we may adopt, it is plain that these variations are observed. Whether we agree to say that carbon is divalent in carbon monoxide and tetravalent in carbon dioxide, or to call carbon dioxide a saturated compound and the monoxide an unsaturated compound, the facts remain the same; and the most important thing to be done is to discover the laws which express the variations in composition. This subject has received considerable attention, but a law which shall express all cases has not been deduced. Nevertheless a fact of great importance has been learned. It is this, that the apparent valency of an element in nearly all cases changes from even to even or from odd to odd, and but rarely from odd to even or *vice versa*. Thus the valency of phosphorus changes from three to five, and all compounds of phosphorus can be explained by assuming that the element is either trivalent or pentavalent, and there are no facts known which indicate that it is ever divalent or tetravalent. Sulphur, on the other hand, is apparently divalent in hydrogen sulphide,  $\text{SH}_2$ , tetravalent in sulphur dioxide,  $\text{SO}_2$ , and in the tetrachloride,  $\text{SOCl}_2$ , and hexavalent in sulphur trioxide,  $\text{SO}_3$ ; and there is no compound of sulphur requiring the assumption that the element is ever monovalent, trivalent, or pentavalent. Elements whose valencies are expressed by an even number have been called *artads*, and those whose valencies are expressed by an uneven number have been called *perissads*. Although the

division of the elements into *artids* and *perissads* is justified by many facts, there are a few which show clearly that the law is subject to exceptions. The most prominent of these are the oxides of nitrogen, nitric oxide, NO, and the peroxide, NO<sub>2</sub>. Plainly in neither of these is nitrogen trivalent or pentavalent. In the former it appears to be divalent, and in the latter tetravalent, the compounds corresponding in composition to the two oxides of carbon. It is true there is nothing to prevent our regarding the nitrogen as monovalent in nitric oxide, and perhaps representing its structure thus =N—O—; but we shall hardly make much progress if we are willing to make use of such methods to deceive ourselves by supposing that we are thus helped out of difficulties; and it should be said, for the credit of chemists, that this suggestion has not been made, so far as is known to the writer.<sup>1</sup>

The law of variation in the composition of compounds, or in the valency of the elements, is highly suggestive of the law which expresses the variations in what may be called the valency of certain hydrocarbons. The hydrocarbon, C<sub>2</sub>H<sub>10</sub>, is a saturated compound, and is not capable of combining directly with atoms or molecules. In this sense it has no valency, and is to be compared to the elements in the state of molecules. As is well known, the simplest change which can take place in hexane, to convert it into a compound with active valencies, is the abstraction of two atoms of hydrogen. In this way the hydrocarbon, C<sub>2</sub>H<sub>8</sub>, or hexylene, is formed. This compound is divalent. An intermediate monovalent compound cannot be obtained. The next change of the same kind gives a compound, C<sub>2</sub>H<sub>6</sub>, which is tetravalent; and thus successively are formed the hexavalent compound, C<sub>2</sub>H<sub>4</sub>, and the octovalent compound, C<sub>2</sub>H<sub>2</sub>. The valencies of these compounds are then 2, 4, 6, and 8, the variations following the same law as is observed in the case of the elements. The variations in the case of the hydrocarbons are commonly explained by assuming different kinds of union between the carbon

atoms. The hexavalent group  $\begin{array}{c} \diagup \text{C} - \text{C} \diagdown \\ | \quad | \end{array}$  becomes tetravalent by the establishment of double union between the carbon atoms, giving a group  $\begin{array}{c} | \\ \text{C} = \text{C} \\ | \end{array}$ , and it becomes divalent by the establishment of triple union between the carbon atoms as indicated thus, —C≡C—. Other possibilities present themselves when we have a compound containing more than two atoms of carbon in the molecule. As has already been shown this same method of explanation has been used in the cases of the compounds of mercury, copper, and iron, but it is plainly not directly applicable to the phosphorus compounds, or the sulphur compounds above referred to. It has been suggested by Professor Sylvester (*v. Am.* 1, 54) that the variation in the valency of elements may

be accounted for by supposing each *n*-valent atom to be made up of *n*-trivalent atomicules united in such a way as to leave one valency of each atomicule free. The explanation is fanciful, but may perhaps prove of some service.

In studying the valencies of the elements in connexion with their position in the periodic system, certain regularities appear which are of great interest. As regards the hydrogen valency it is a noteworthy fact that the elements of the first three groups in Mendeleeff's table do not unite with hydrogen. Beginning with carbon in the fourth group the hydrogen valency decreases regularly, as is shown in the following table:—

Group	1	2	3	4	5	6	7
Element	Li	Be	B	C	N	O	F
Hydrogen compound	—	—	—	CH <sub>4</sub>	NH <sub>3</sub>	OH <sub>2</sub>	HF

Taking next the chlorine valency we find, beginning with Group 1, a regular increase to Group 4, and then a regular decrease, as is shown in this table:—

Group	1	2	3	4	5	6	7
Element	Na	Mg	Al	Si	P	S	Cl
Chlorine compound	NaCl	MgCl <sub>2</sub>	AlCl <sub>3</sub>	SiCl <sub>4</sub>	PCl <sub>5</sub>	SOCl <sub>2</sub>	Cl <sub>2</sub>

Towards oxygen the valency increases regularly from Group 1 to Group 7, as shown thus:—

Group	1	2	3	4	5	6	7
Element	Na	Mg	Al	Si	P	S	I
Oxygen compound	Na <sub>2</sub> O	MgO	Al <sub>2</sub> O <sub>3</sub>	SiO <sub>2</sub>	P <sub>2</sub> O <sub>5</sub>	S <sub>2</sub> O <sub>7</sub>	I <sub>2</sub> O <sub>7</sub>

This series of oxygen compounds is of special interest. One cannot study it impartially without reaching the conclusion that we have here to deal with a regular increase in the valency from 1 to 7. Any other conclusion involves an explanation for the compounds P<sub>2</sub>O<sub>5</sub>, SO<sub>2</sub>, and I<sub>2</sub>O<sub>7</sub>, entirely different from that which we make use of for the other oxygen compounds in the series. Further, when we consider the hydroxyl derivatives of these elements, we shall see that it is impossible to deal with them satisfactorily on any other assumption than that phosphorus is tetravalent, sulphur hexavalent, and iodine heptavalent towards oxygen. This is perhaps most strikingly shown in the case of periodic acid. This compound is commonly represented by the formula HIO<sub>4</sub>, and the structure H—O—O—O—O—I is given to it. It can easily be shown, however, that on this assumption most of the salts of periodic acid cannot be explained. Whereas, if the periodates be considered as derived from several acids, all of which are in turn derived from the normal periodic acid I(OH)<sub>7</sub>, by processes of dehydration, they can all be explained without serious difficulty. The acid HIO<sub>4</sub>, according to this, is derived from normal periodic acid thus: I(OH)<sub>7</sub> = O<sub>2</sub>I(OH)<sub>5</sub> + 2H<sub>2</sub>O; and in it the iodine is regarded as heptavalent, holding three atoms of oxygen and one hydroxyl. In a similar way sulphuric acid is regarded as derived from the normal acid or maximum hydroxyl compound S(OH)<sub>6</sub>, by loss of water:

According to this, in sulphuric acid the sulphur is hexavalent, holding two atoms of oxygen and two hydroxyls. Several facts which have come to light in the study of derivatives of sulphuric acid speak in favour of this view, or at least against

<sup>1</sup> There are several exceptions to the so-called law of *artids* and *perissads*; InCl, and InCl<sub>3</sub>, and probably also InCl<sub>2</sub>, exist as gases; WO<sub>3</sub> and WO<sub>2</sub>; CrCl<sub>3</sub> probably exists as a vapour, besides CrCl<sub>4</sub>; HgCl<sub>2</sub> is probably the molecular formula of calomel, while the composition of the molecule of corrosive sublimate is represented by the formula HgCl<sub>2</sub>.—M. M. F. M.

the view sometimes held that the acid is constituted thus,  $\text{HO}-\text{O}-\text{S}-\text{O}-\text{OH}$ . In short, whether we study the elements with reference to their positions in the periodic system or with reference to the chemical transformations of their compounds, we are led to the conclusion that the more probable view in regard to their valency towards oxygen is that it increases regularly from 1 to 7 from Group I. to Group VII.; and that the valency of the elements towards hydrogen is quite different from their valency towards oxygen, except in Group N. Taking the last four groups it is seen that as the valency towards hydrogen decreases the valency towards oxygen increases:

Group	4	5	6	7
Hydrogen compound	$\text{SiH}_4$	$\text{PH}_3$	$\text{SH}_2$	$\text{IH}$
Oxygen compound	$\text{SiO}_2$	$\text{P}_2\text{O}_5$	$\text{S}_2\text{O}_7$	$\text{I}_2\text{O}_5$

It appears from further study that the valency of an element towards hydrogen is constant, while towards chlorine and oxygen it is evident from what has already been said that the valency varies. Except in the fourth group the maximum valency is never exhibited towards hydrogen. Chlorine occupies an intermediate place. In the fourth and fifth groups the valency towards chlorine is the same as towards oxygen. In the sixth group the valency towards hydrogen is two, towards oxygen six, and towards chlorine, as shown by the highest chlorine compound of sulphur, it is four. In the seventh group the valency towards hydrogen is one, and towards oxygen seven, while the highest valency shown towards chlorine by a member of this group is three, as in the compound  $\text{ICl}_3$ . Towards fluorine, however, the valency of iodine is five, as shown by the compound  $\text{IF}_5$ .

The facts just referred to show beyond question that the valency of an element is not a constant property, residing as it were in the element, but that it is determined to some extent by external circumstances, and particularly by the character of the element with which an element is brought in contact. We find analogy for this in the conduct of some acids towards bases. Thus, ordinary phosphoric acid is commonly spoken of as a tribasic acid, but its basicity is to some extent dependent upon the character of the base with which it reacts. Strictly speaking it is only dibasic towards sodium hydroxide, while towards most other bases it is tribasic. The intensity of the action of the acid towards sodium hydroxide is greater than towards most other bases, and after the acid has taken up two atoms of sodium its power is nearly exhausted. It can, to be sure, take up a third atom of sodium, but the compound thus formed is very unstable. But it can take up and hold firmly in combination three atoms of silver. Considering the differences in the valency of any element towards other elements, it appears in general that the valency is small towards an element with which it combines with much energy, while it is larger towards an element with which it combines with little energy. This is well illus-

<sup>1</sup> If by the valency of an element is meant the maximum number of atoms with which one atom of the given element can be directly associated in a gaseous molecule, then conclusions about the valency of this or that element must be drawn, at present, only from a study of gaseous molecules. In this case, some of the remarks about the valencies at I, II, &c., in these paragraphs would be rather irrelevant.

M. M. P. M.

trated by the compounds of chlorine with hydrogen and with oxygen.

The phenomena studied under the head of valency show clearly that, when atoms combine to form a molecule, they are not merged into one homogeneous mass, but are arranged with a certain definiteness; and the study of the facts of isomerism confirms this view in a striking way. We speak of the atoms as being linked together, and this linking is found to take place according to the laws of valency. By the constitution or structure of a compound is meant the way in which the atoms are linked together. The constitution is expressed by means of a formula which is intended to show—on the basis of certain assumptions, and by the help of several conventions—how the atoms are linked together. Thus

the formulae  $\text{H}-\text{O}-\text{H}$ ,  $\text{O}_2\text{S} \begin{smallmatrix} \text{O}-\text{H} \\ \diagup \quad \diagdown \\ \text{O}-\text{H} \end{smallmatrix}$ , &c., are constitutional formulae. These are determined by

methods which will be considered in the article FORMULÆ. It need only be remarked here that they are determined chiefly by studying the reactions of compounds, and the methods by which they are built up from simpler substances. The reactions being known, they are interpreted in terms of the atomic theory and the hypothesis of the linkage of atoms.

To sum up in a few words the chief conclusions which we are justified in drawing in regard to valency:—

The so-called theory of types was the forerunner of the valency hypothesis.

Frankland first recognised the fact that the power of atoms to unite with other atoms is limited to a definite number of other atoms.

Kekulé and Couper elaborated the valency hypothesis, and showed how it may be used to explain chemical compounds.

The facts show plainly that valency is not a constant property of the elements, but that it varies: (1) according to the nature of the uniting elements; (2) according to surrounding circumstances, such as the temperature.

Valency is not to be thought of as determined by a certain number of points of attraction in the atom, but rather as a condition—perhaps a form of motion. Valency is a function of the atomic weights of the elements. I. R.

**ERBIUM** Er. At. w. 166. Mol. w. unknown as element has not been gasified. Chief lines in emission-spectra: 5826, 5256, 4951 (Cleve, *C. R.* 91, 381).

In 1788 Gadolin, professor at Abo, found a new earth in a mineral from Ytterby in Sweden; the discovery was confirmed by Ekeberg in 1797, and the new earth was called *Yttria*. The examination of yttria from *Gadolinite* (the mineral was thus named after Gadolin) by Berzelius (1819), Mosander (1839 and 1843), and Scheerer (1842), led to the recognition of seven earths in what had been regarded by Gadolin as a homogeneous substance, viz. beryllia, lanthana, ceria, didymia, yttria, erbia, and terbia. Many researches were conducted in the years 1860–1878 on the earths from *Gadolinite*; some of the results pointed to the non-existence of terbia as a distinct earth, while others made the existence of this body very probable; the investigations of Cleve seem to show that terbia is a definite earth. The substance to which the name of erbia had been

given was very carefully examined by Marignac in 1878, and subsequently by Nilson, and then by Cleve, with the result that it was shown to be a mixture of the three earths ytterbia, scandia, and erbia, and to these Cleve afterwards added two others, viz. holmia and thulia. The investigation of these earths is yet far from complete.

To obtain the crude earths from *Gadolinite*, Bahr a. Bunsen (*A.* 137, 1) decompose the mineral by  $\text{HClAq}$ , separate  $\text{SiO}_2$  by evaporation to dryness and addition of  $\text{HClAq}$ , heat to boiling, and ppt. by oxalic acid; they wash the pp., convert the oxalates into nitrates, and ppt. the cerium compounds by addition of  $\text{K}_2\text{SO}_4$ ; the earths of the erbium group are then ppd. from the filtrate by oxalic acid, the oxalates are heated in a Pt dish, the carbonates thus obtained are boiled in water (to dissolve out  $\text{KCO}_3$ ), and dissolved in  $\text{HNO}_3\text{Aq}$ ; oxalic acid is again added, and the ppd. oxalates are once more converted into carbonates by heating; the carbonates are tested for didymium by observing the absorption-spectrum of a very conc. solution in  $\text{HNO}_3\text{Aq}$ ; if Di is present the treatment with  $\text{K}_2\text{SO}_4$  is repeated until a pp. is obtained free from Di; the earths are then ppd. by  $\text{NH}_4\text{Aq}$  free from  $(\text{NH}_4)_2\text{CO}_3$ ; the pp. is dissolved in  $\text{HNO}_3\text{Aq}$ , and the oxalates are ppd. by addition of oxalic acid. There are different methods for obtaining erbia from the mixed oxalates. Auer v. Welsbach recommends the following (*M.* 4, 630). The oxalates are converted into oxides by heating strongly, the oxides are made into a paste with water and thrown into a quantity of hot nitric acid insufficient for their complete solution; a basic erbium nitrate containing yttria forms on cooling; the process is repeated several times; at last, when there is a considerable quantity of undissolved oxide in the boiling nitric acid, the whole becomes somewhat pasty and greyish-red in colour; the mass is now allowed to cool, and conc. nitric acid is added in small successive quantities until the colour becomes reddish. The acid dissolves compounds of Ce and traces of Fe salts; a compact rose-coloured pp. settles down, from which the mother-liquor can be poured off. The pp. is washed with alcohol with the aid of a filter-pump; the alcohol dissolves nitrates but leaves the basic nitrates. The pp., which consists of basic erbium nitrate containing yttrium nitrate, is purified by a long and tedious process, based on the fact that basic erbium nitrate is produced more readily than the basic yttrium salt by heating the mixed nitrates with the oxides of the metals, and that the basic yttrium salt is more soluble than the erbium salt in liquid containing the normal nitrates. Another method of obtaining basic erbium nitrate consists in heating the mixed nitrates (formed by dissolving the oxides or carbonates in  $\text{HNO}_3\text{Aq}$ ) in a Pt dish until red fumes are evolved, and a portion of the residue is insoluble in water; the insoluble portion is again heated, and then treated with water, and so on (Marignac, *A. Ch.* [5] 14, 247; Cleve, *C. R.* 91, 881).

R.* 87, 578. Nilson, *C. R.* 88, 645; 91, 118. De Boisbaudran, *C. R.* 88, 322; 89, 212. Von Welsbach, *M.* 4, 630.

The metal erbium has not yet been isolated. The atomic weight was determined by Delafontaine (*Ar. Sc.* 1866. 112), Cleve a. Höglund (*Bl.* [2] 18, 193, 289), Humpidge a. Burney (*C. J.* 35, 11), but the results were too high. Cleve re-determined the at. w. by synthesising the sulphate from pure  $\text{Er}_2\text{O}_3$ ; he obtained the value 166.15 (*C. R.* 89, 706; 91, 381).

So far as the investigation of Er compounds has gone, it shows that this metal is best placed in Group V, in the odd series 9, between Sb and Bi; Er is also analogous to the earth-metals Sc, Y, La, and Yb, and it shows resemblances to Ce (*cf.* NITROGEN GROUP OF ELEMENTS, and EARTHS, METALS OF THIS).

**Erbium, haloid compounds of.** Erbium bromide, chloride, fluoride, and iodide,  $\text{ErX}_3$  ( $\text{X} = \text{Br}, \text{Cl}, \text{F}, \text{I}$ ), have been described; but as the material worked with was not known to be perfectly free from other metals of the yttria group, but little stress can be laid on the descriptions given. These compounds are said to be rose-coloured and deliquescent.

**Erbium, oxide of.**  $\text{Er}_2\text{O}_3$ . S.G. 8.64. S.H. .065. S.V.S. 43.98 (Nilson a. Pettersson, *B.* 13, 1459). Emission-spectrum characterised by bright lines 6546 (red), 5631 and 5397 (yellow), 5228 and 5204 (green) (Bahr a. Bunsen, *A.* 137, 1; De Boisbaudran, *C. R.* 76, 1080; 88, 1167, 1342; 89, 212, 516); the dark lines of the absorption-spectrum of the solution of an Er salt correspond with these. Obtained by heating the nitrate or oxalate in air. Pale rose-coloured powder. Not changed when heated in H. Infusible; glows with intense green light when heated, without volatilising. Slowly dissolved by hot  $\text{HNO}_3\text{Aq}$ ,  $\text{H}_2\text{SO}_4\text{Aq}$ , or  $\text{HClAq}$ . Does not directly combine with water.

**Erbium, salts of.** Compounds obtained by replacing H of acids by Er. These salts are formed by dissolving  $\text{Er}_2\text{O}_3$  in acids; many are also formed by double decomposition from the sulphate or nitrate. Solutions of Er salts are more or less rose-coloured; they generally have an acid reaction with litmus, and taste sweetish but astringent. The salts all belong to the form  $\text{Er}_3\text{X}$  where  $\text{X} = \text{SO}_4, 2\text{NO}_3, \frac{2}{3}\text{PO}_4$ , &c.; a few basic salts, e.g.  $\text{Er}_2\text{O}_3 \cdot 2\text{CO}_3$ , have been obtained. The principal salts are the bromate, carbonate, chlorate and perchlorate, formate, iodate and periodate, nitrate, oxalate, selenate and selenite, sulphate and sulphite, and phosphate (*v.* CARBONATES, NITRATES, &c.). M. M. P. M.

**ERGOSTERIN**  $\text{C}_{28}\text{H}_{48}\text{O}$ . [154°]. S.G. 1.04.  $[\alpha]_D = -114^\circ$ . Extracted from ergot of rye (Tanret, *C. R.* 108, 98). Pointed needles (containing aq); sol. alcohol and ether; insol. water. Slowly oxidises in air, very rapidly at 100°. Is not attacked even by hot concentrated alkalis. Resembles cholesterol in many reactions, but gives different results with sulphuric acid and chloroform. The acid dissolves the ergosterin, and agitation with chloroform gives

no colouration till evaporation takes place, when a trace of violet appears.

**Formyl derivative**  $C_{20}H_{33}(CHO)O$ . [154°].  $[\alpha]_D = -93.4^\circ$ . Spangles, sol. ether.

**Acetyl derivative**  $C_{20}H_{33}AcO$ . [169°].  $[\alpha]_D = -80^\circ$ . Pearly spangles, sol. ether and alcohol, insol. water.

**Butyryl derivative**  $C_{20}H_{33}(C_4H_7O)O$ . [95°].  $[\alpha]_D = -57^\circ$ .

**ERGOTININE**  $C_{20}H_{33}N_2O_5$ . *Ecboline*. S. (95 p.c. alcohol).  $[\alpha]_D = 137.5^\circ$ . Occurs in ergot of rye, together (according to Dragendorff) with 'scleromucin,' 'sclerotic acid,' 'sclererythrin,' 'sclerocrystallin'  $C_{10}H_{15}O_4$ , 'scleroxanthin'  $C_{10}H_{15}O_4$ , a hydrate of sclerocrystallin, mycose, mannite, cholesterolin, leucine, lactic acid, methylamine, and trimethylamine (Wiggers, A. 1, 171; Manassewitz, Z. [2] 4, 154; Denzel, Ar. Ph. [3] 22, 49; Dragendorff, Ar. Ph. 7, 82; C. C. 1878, 125; Bombelon, C. C. 1888, 472). Ergot also contains a fatty oil (Hermann, Rep. Pharm. 20, 283; Ganser, Rep. Pharm. 20, 301). Tanret (J. Ph. 26, 320; C. J. 34, 81) also obtained from ergot a crystalline substance, smelling like camphor [165°], (209°), insol. water, sol. alcohol, and chloroform. Kobert (J. 1884, 1512) describes ergot as containing cornutine and sphacelic (ergotic) acid.

**Preparation.**—The ergot is exhausted with alcohol, caustic soda is added to alkaline reaction, the alcohol is distilled off, and the residue agitated with ether. The ethereal extract is then shaken with a concentrated solution of citric acid, the citrate is decomposed by  $K_2CO_3$ , and the ergotinine extracted by ether, from which it crystallises. In this way 1.2 g. is got from 1 kilo of ergot (Tanret, A. Ch. [5] 17, 499; C. R. 81, 896; 86, 888; cf. Blumberg, Ph. [3] 9, 23, 598).

**Properties.**—Delicate prismatic needles, turning brown in air. Insol. water, sol. alcohol, ether, and  $CHCl_3$ . When the ergot is old an amorphous substance (modification of ergotinine) present, which increases its solubility in alcohol. Its solutions fluoresce violet. The rotatory power of the amorphous ergotinine  $[\alpha]_D = 122^\circ$  is less than that of the crystalline variety. Ergotinine gives all the general tests characteristic of alkaloids. When a drop of  $H_2SO_4$  is added to its solution in acetic acid a red colouration passing rapidly to violet and blue is formed. Ergotinine when injected hypodermically produces intoxication.

**Salts.**— $BHCl$ .— $BHBr$ .

**ERICIN.** A dye-stuff in *Erica vulgaris*. It gives a bronze-green pp. with iron salts, a golden-green pp. with tin salts, and a green colour with copper salts (Savigny a. Collineau, C. C. 1881, 703; C. J. 42, 309).

**ERICINONE**  $C_{20}H_{33}O$  (?).  $[\alpha]_D = 167^\circ$ . An indifferent crystalline substance, said by Uloth (A. 111, 216) to be obtained by the dry distillation of ericaceous plants. May be sublimed.

**ERICOLIN**  $C_{20}H_{33}O_2$ . A resinous glucoside found in several plants of the heath family, e.g. common ling (*Calluna vulgaris*), wild marsh rosemary (*Ledum palustre*), in the red bearberry (*Arctostaphylos uva ursi*), in *Gaultheria procumbens*, in *Epigaea repens*, and in *Rhododendron ferrugineum* (Roehleider a. Schwarz, A. 84, 354, 368; Kawaler, Sitz. W. 9, 29; Ozley, Ph. [3] 2, 1050; Thal, J. 1888, 1401). It has a bitter

taste. Dilute acids split it up into glucose and ericicol.

**Ericinol**  $C_{20}H_{33}O_2$ . Formed, together with glucose, by distilling ericicol or pinipierin with dilute  $HCl$  or  $H_2SO_4$ . Volatile oil, turning brown in the air (Roehleider; Kawaler; Thal; Fröhde, J. pr. 82, 181). Ericinol takes up water, becoming 'ericinol hydrate'  $C_{20}H_{33}O_3$ , which has a very characteristic odour (Thal).

**ERIGERON OIL.** The volatile oil from *Erigeron canadense* contains a terpene (1176°). S. G. 12.848.  $[\alpha]_D = 6^\circ 15'$ , identical with citrène and hesperidene (Wallach, A. 227, 292; cf. Vigier a. Cloëz, J. Ph. [5] 4, 333).

**ERUCIC ACID**  $C_{22}H_{41}O_2$ . *Brassicid acid*. Mol. w. 338. [34°]. An acid occurring as glyceryl ether in colza-oil (Welsky, J. pr. 58, 449; Staedeler, A. 87, 133; Otto, A. 127, 182; 135, 226; Haussknecht, A. 143, 40), in the fixed oil of white mustard (*Sinapis alba*), and of black mustard (Darby, A. 69, 1; Goldschmiedt, Sitz. W. [2] 70, 451; 74, 394), and in the fatty oil from grape seeds (Fitz, B. 4, 442).

**Preparation.**—Rape-seed oil is saponified by alcoholic KOH; after distilling off most of the alcohol the fatty acids are precipitated with dilute  $H_2SO_4$ , separated, and dissolved in three times the weight of 95 p.c. alcohol; on cooling the solution to  $0^\circ$  the erucic acid crystallises out, and is recrystallised in the same way (Reimer a. Will, B. 19, 3320). Long needles (from alcohol). Decomposed by potash-fusion into acetic and arachic acids. Br forms the dibromide  $C_{22}H_{39}Br_2O_2$  (43°) (v. Di-bromo-erucic acid). Nitrous acid converts erucic acid into the isomeric brassic acid (q. v.). HI and P at  $200^\circ$  give behenic acid.

**Salts.**— $NaA'$ .— $BaA'_2$ .— $PbA'_2$ .— $AgA'$ .

**Ethyl ether  $EtA'$**  (above  $300^\circ$ ); colourless odourless oil; converted by nitrous acid into ethyl brassate.

**Glycerin-di-erucic ether**  $C_2H_5(OEt)A'_2$ . *Dierucin*. [47°]. Silky colourless crystals (from ether-alcohol). Occurs as a deposit from rapeseed oil after long standing. V. sol. ether and ligroin, m. sol. hot alcohol, insol. cold alcohol. By nitrous acid it is converted into glycerin-dibassic ether.

**Glycerin-tri-erucic ether**  $C_3H_7A'_3$ . *Tri-erucin*. [31°]. From erucic acid and glycerin at  $300^\circ$ .

**Amide**  $C_{21}H_{41}.CONH_2$ : [84°]; colourless needles; v. sol. ether and benzene, sl. sol. alcohol, insol. water. Formed by the action of  $NH_3$  gas upon the anhydride.

**Anilide**  $C_{21}H_{41}.CONHPh$ : [55°]; crystals; v. sol. ether and benzene, sl. sol. alcohol.

**Anhydride**  $(C_{22}H_{41}.CO)_2O$ : oil which solidifies in a freezing mixture; v. sol. ether and benzene, v. sl. sol. alcohol. Formed by the action of  $PCl_5$  upon erucic acid and subsequent addition of alcohol (Reimer a. Will, B. 19, 3320).

**ERYTHRENE v. BUTYRENE.**

**Erythrene bromide v. Tetra-bromo-butane and Di-bromo-butylene.**

**ERYTHRIN**  $C_2H_2O_2$ , i.e.  $C_4H_8(C_2H_3O)_2O$ . *Erythric acid*. Mol. w. 422. [187°]. S. 42 at  $100^\circ$ ; S. (ether) 3 at  $20^\circ$ . Occurs in *Roccella tinctoria*, *R. Montagnei*, *R. fuciformis* and other lichens (Heeren, Schuss. J. 59, 818; Kane, A. 89, 25; Schunck, A. 61, 69; Stenhouse, A. 88, 72;

Pr. 12, 268; C. J. 20, 222; Hesse, A. 117, 804; De Luynes, A. Ch. [4] 2, 385; Menschutkin, Bl. [2] 2, 424). Extracted by milk of lime, and p.p.d. by HCl. Crystalline mass (containing  $1\frac{1}{2}$  aq.). Sl. sol. water, v. sol. alcohol and ether. Its alcoholic solution gives a violet colour with  $\text{Fe}_2\text{Cl}_6$ .

**Reactions.**—1. Boiling water or alkalis split it up into orsellic acid  $\text{C}_9\text{H}_6\text{O}_4$  and picroerythrin  $\text{C}_{11}\text{H}_{10}\text{O}_8$ ; the orsellic acid being resolved by longer boiling into  $\text{CO}_2$  and orcin. Boiling alcohol produces, in the same way, orsellic ether and picroerythrin. Methyl and amyl alcohols act in like manner.—2. Boiling with excess of lime-water gives erythrite, orcin, and  $\text{CO}_2$  (Lamparter, A. 134, 255).—3. Bromine forms  $\text{C}_{20}\text{H}_{18}\text{Br}_2\text{O}_{10}$ .

**Metallic derivatives.**— $\text{C}_{20}\text{H}_{18}\text{PbO}_{10}$ , aq.  $\text{Pb}_3(\text{C}_{20}\text{H}_{18}\text{O}_{10})_2$ , 3aq.— $\text{C}_{20}\text{H}_{18}\text{Pb}_2\text{O}_{10}$ .— $\text{Pb}_2(\text{C}_{20}\text{H}_{18}\text{O}_{10})_2$ .

( $\beta$ )-Erythrin  $\text{C}_{21}\text{H}_{20}\text{O}_{10}$ . Occurs in *Roccella fuciformis* (Menschutkin, Bl. [2] 2, 424). White crystalline powder (containing aq.). Nearly insol. water, sol. alcohol, and ether. Decomposed by boiling alcohol or water into orsellic ether or acid and ( $\beta$ )-picroerythrin. Boiling baryta splits it up into erythrite,  $\text{CO}_2$ , and betorcin.— $\text{Pb}_2\text{C}_{21}\text{H}_{20}\text{O}_{10}$ .

Erythrin v. Bromo-Fluorescein.

ERYTHRITE  $\text{C}_4\text{H}_6\text{O}_4$ , i.e.

$\text{CH}_2(\text{OH})\text{CH}(\text{OH})\text{CH}(\text{OH})\text{CH}_2(\text{OH})$ . Erythrol. Erythromannite. Erythroglycerin. Eryglucin. Phycite. Mol. w. 122. [112°]. S.G. 1.45 (Schroder, B. 12, 562).  $R_{\infty}$  43.65 (in a 14 p.c. aqueous solution) (Kanonnikoff, J. R. 15, 449). Heat of solution—5200 at 9° (Colson, C. R. 104, 113). Occurs ready-formed in *Protococcus vulgaris* and is produced by the action of boiling lime or baryta upon erythrin or picroerythrin (Stenhouse, Tr. 1848, 76; 1849, 399; Strecker, A. 68, 111; Schunck, P. M. 7, 33, 254; Lamy, A. Ch. [3] 85, 138; 51, 232; Wagner, J. pr. 61, 125; Hesse, A. 117, 327; Hofmann, B. 7, 512; De Luynes, A. Ch. [4] 2, 339; C. R. 56, 803).

**Properties.**—Large dimetric crystals with sweet taste. Inactive. Neutral to litmus. V. sol. water, sl. sol. cold alcohol, insol. ether. Does not reduce Fehling's solution. Is not p.p.d. by lead subacetate. Its aqueous solution dissolves lime, a pp. being formed on boiling or on adding alcohol. Does not undergo alcoholic fermentation. Like other polyhydric alcohols, it renders a solution of borax acid (Dunstan, Ph. [3] 13, 257). In presence of vegetable mould it undergoes butyric fermentation (Witz, B. 11, 1890; 12, 476). Erythrite does not react when heated with aldehyde or isobutyric aldehyde at 125° (Loechert, A. Ch. [6] 18, 64).

**Reactions.**—1. Potash-fusion gives acetic and oxalic acids.—2. Fuming nitric acid forms the nitrate. Dilute nitric acid oxidises it to oxalic and tartaric acids (Przybytek, Bl. [2] 35, 108); at the same time there is formed an aldehyde or ketone whose phenyl-hydrazide  $\text{C}_{10}\text{H}_{12}\text{N}_4\text{O}_5$  melts at [167°] (Fischer a. Tafel, B. 20, 1088).—3.  $\text{CrO}_3$  and  $\text{KMnO}_4$  give formic and oxalic acids.  $4\text{H}_2\text{SO}_4$  forms a sulphuric acid  $\text{C}_4\text{H}_4\text{O}_6(\text{SO}_3\text{H})_2$  (Hesse, A. 117, 329). The salts  $\text{Ca}_2\text{A}''''$ , 6aq.,  $\text{Ba}_2\text{A}''''$ , 6aq., and  $\text{Pb}_2\text{A}''''$ , 12aq. have been described.—4. Heating with aqueous HI forms secondary butyl iodide.—5. PBr, gives  $\text{C}_4\text{H}_5\text{Br}$  [112°] (Colson, C. R. 104, 113).—6. Yields

thiophene by heating with  $\text{P}_2\text{S}_5$  (Paal a. Tafel, B. 18, 688).—7. Distillation with  $\text{S}_2\text{Cl}_2$  under 100mm. pressure yields a substance ( $\text{? C}_4\text{H}_4\text{SO}_4$ ) which crystallises from ether in needles [115°] (Henninger, A. Ch. [6] 7, 231).—8. Formic acid produces several formins, including the crystalline tetraformin  $\text{C}_4\text{H}_4(\text{OCHO})_4$ . When the mixture of formins is distilled at 250° there is given off  $\text{CO}_2$ , butene, and  $\text{CO}$ , and a liquid distils over consisting of water, formic acid, crotonic aldehyde, di-oxy-butylene (crotonylene glycol),  $\text{C}_4\text{H}_4(\text{OH})_2$ , 'dihydrofurfurane' ( $\text{C}_4\text{H}_4\text{O}_2$ , (67°), and the anhydride of erythrite  $\text{C}_4\text{H}_2\text{O}_4$  (Henninger, C. R. 98, 149; A. Ch. [6] 7, 210; Bl. [2] 19, 2, 145; 21, 242).—9. Phenyl cyanate (4 mols.) heated with erythrite (1 mol.) forms  $\text{C}_4\text{H}_2(\text{O.CO.NHPh})_4$  [215°] a microcrystalline solid, sl. sol. alcohol and ether (Tessmer, B. 18, 970).

**First Anhydride**  $\text{C}_4\text{H}_2\text{O}_4$ . Erythrane. (155°) at 18 mm.

**Formation.**—1. A product of the action of formic acid on erythrite.—2. By heating erythrite with equal weights of water and conc.  $\text{H}_2\text{SO}_4$ .—3. In small quantity by the action of HCl on erythrite.

**Properties.**—Liquid. Conc. HCl converts it into erythrite dichlorohydrin (Henninger, A. Ch. [6] 7, 225).

**Second Anhydride**  $\text{C}_4\text{H}_2\text{O}_4$ , i.e.

$\text{CH}_2\text{CH}(\text{CH}_2\text{CH}_2\text{O})_2$  (?). Erythrite dioxide. Erythrane. (138°). S.G. 2 1.132; 12 1.113. C.E. (0°-18°) 00095. V.D. 3.16 (obs.). Formed by treating erythrite dichlorohydrin in ethereal solution with KOH, the yield being 70 p.c. (Przybytek, B. 17, 1092; Bl. [2] 41, 393; 42, 322). Mobile liquid, miscible with water. Slowly unites with water to form erythrite. Combines with HCl reproducing the dichlorohydrin. Unites with HCN to form the nitrile of di-oxy-adipic acid. Readily combines with  $\text{NH}_3$  and amines. Aniline forms a compound  $\text{C}_{10}\text{H}_{10}\text{N}_2\text{O}_4$ . Reduces  $\text{AgNO}_3$  forming a mirror. Ppts. MgO from magnesium salts.

**Isomeride of the Second Anhydride**  $\text{C}_4\text{H}_2\text{O}_4$  [173°]. Formed, together with  $\text{C}_4\text{H}_4(\text{OH})(\text{OEt})_2$ , by the action of NaOEt upon erythrite dichlorohydrin, or by treating the dichlorohydrin with powdered NaOH (Henninger, A. Ch. [6] 7, 225). Plates (from alcohol).

**Di-ethyl ether**  $\text{C}_4\text{H}_4(\text{OH})(\text{OEt})_2$  [135°]. (141°) at 22 mm. From the dichlorohydrin and NaOEt at 100° (Henninger, A. Ch. [6] 7, 230).

**Erythrite tetranitrate**  $\text{C}_4\text{H}_2(\text{NO}_3)_4$ . Nitroerythrite. [61°]. Formed by dissolving erythrite in cold fuming  $\text{HNO}_3$  and ppg. by the addition of  $\text{H}_2\text{SO}_4$  (Stenhouse, Tr. 1849, 399). Large plates (from alcohol). Insol. cold water. Explodes when struck. Alcoholic ammonium sulphide reconverts it into erythrite.

**Erythrite tetra-sulphuric acid**  $\text{C}_4\text{H}_2(\text{SO}_3\text{H})_4$ . Deliquescent crystals got by dissolving erythrite in  $\text{ClSO}_3\text{H}$ . Boiling water slowly resolves it into erythrite and hydric sulphate (Claesson, J. pr. [2] 20, 7).

**Salts.**— $\text{K}_2\text{A}''''$ , 4aq. Nearly insol. cold water.  $\text{BaA}''''$ , 4aq. Insol. water. Ppd. by adding  $\text{BaCl}_2$  to a solution of the free acid but not to one of the potassium salt (Claesson).

**Mono-formyl derivative**  $C_4H_4(OH)_2(O.CHO)$ . *Erythrite monoformin*. (192°). Formed, together with the following, by boiling erythrite (1 pt.) with formic acid (2½ pts.) for 6 hours (Henninger, *A. Ch.* [6] 7, 215).

**Tetra-formyl derivative**  $C_4H_4(O.CHO)_4$ . [150°]. Prepared by heating erythrite with formic acid at 200° and extracting with dry ether; the product being treated in the same way with 20 pts. of formic acid (S.G. 1.18). Long needles (from alcohol).

**Benzoyl derivative**  $C_4H_4(OH)_2(OBz)$ . From erythrite and HOBz at 250° (Berthelot, *Chimie organique*, 2, 224). Crystalline mass, insol. water, v. sol. alcohol and ether.

**Tetra-benzoyl derivative**  $C_4H_4(OBz)_4$ . From the preceding (1 pt.) and HOBz (15 pts.) at 200° (B.). Nearly insol. water.

**Orsellyl derivative**  $C_4H_4O_4$ , i.e.  $C_4H_4(OH)_2(O.CO.C_6H_4(OH)_2Me)$ .

**Picroerythrin**. [158°]. Obtained by boiling erythrin with water, alcohols, or alkalis (Schunck, *A.* 61, 64; Stenhouse, *A.* 68, 76; Hesse, *A.* 117, 321). Silky prisms (containing 3aq). Tastes bitter. V. e. sol. hot water. Decomposed by boiling lime-water into erythrite, orcin, and  $CO_2$ . Gives a purple colour with  $FeCl_3$ .

**(β)-Orsellyl derivative. Anhydride.**  $C_4H_4O_4$ . **(β)-Picroerythrin**. Obtained by boiling (β)-erythrin with alcohol (Menschutkin, *Bl.* [2] 2, 424). Needles, v. e. sol. water and alcohol, insol. ether. Reduces hot silver solution. Split up by boiling with baryta into  $CO_2$  erythrite, and betorein  $C_4H_4O_4$ .

**Erythrite chlorhydrin**  $C_4H_4(OH)_2Cl$ . [66°]. Flat interlacing needles, sol. alcohol, insol. ether.

**Erythrite dichlorhydrin**  $C_4H_4(OH)_2Cl_2$ . [126°]. (152°) at 80 mm. Prepared by heating erythrite (200 g.) with conc.  $HClAq$  (2400 g.) for 6 hours, and distilling the product under reduced pressure. Arborescent mass of crystals, v. sol. alcohol (Henninger, *A. Ch.* [6] 7, 228; Przybylak, *B.* 17, 1091). A mixture of  $HNO_3$  and  $H_2SO_4$  converts it into the nitrate  $C_4H_4(NO_3)_2Cl_2$  [60°] (Champion, *C. R.* 73, 114).

**Erythrite tetrachlorhydrin** v. **TETRA-CHLOROBUTANE**.

**Erythrite dibromhydrin**  $C_4H_4(OH)_2Br_2$ . [130°]. From erythrite and conc.  $HBrAq$  at 110° (Champion, *Z.* 1871, 348; *C. R.* 73, 114). Crystals (from ether), insol. water. A cold mixture of fuming  $HNO_3$  (1 pt.) and conc.  $H_2SO_4$  (2 pts.) forms the nitrate  $C_4H_4(NO_3)_2Br_2$  [75°].

**ERYTHROCENTAUREIN**  $C_4H_4O_4$ . [136°]. S. -06 at 15°; 7 at 100°; S. (86 p.c. alcohol) 2; S. (ether) 4; S. (chloroform) 7. A substance allied to santonin which may be extracted by alcohol from the common centaury (*Erythraea Centaurium*). Tasteless crystals (from ether); neutral to litmus. Inactive. Sol. most menstrua; water ppts. it unaltered from its solution in  $H_2SO_4$ . It turns bright red in sunlight, being affected by the blue or violet rays; the red colour disappears on solution or on heating to 130° (Mehu, *J. Ph.* [4] 8, 265).

**ERYTHROGLUCIC ACID**  $C_4H_4O_4$ , i.e.  $CH_2(OH).CH(OH).CH(OH).CO_2H$ . Obtained by the oxidation of erythrite by air in presence of platinum-black or by nitric acid (Sell, *Bl.* [2] 5, 384; Lamparter, *A.* 134, 243). Deliquescent mass;

v. sol. water and alcohol.— $BaC_4H_4O_4$  aq (L.)—( $C_4H_4PbO_4$ ),  $PbO_4H_4(S_2)$ — $C_4H_4PbO_4$  (at 160°; L.).

**ERYTHRO-OXY-ANTHRAQUINONE** v. **OXY-ANTHRAQUINONE**.

**ERYTHROPHLEINE**. An alkaloid in the bark of *Erythrophloeum guineense* (Gallois a. Hardy, *Bl.* [2] 26, 39). Sol. alcohol, al. sol. ether. Gives a violet colour with  $MnO_2$  and  $H_2SO_4$ .

**ESENBECKINE**. An alkaloid in the bark of *Esenbeckia febrifuga* (Buchner, *Rep. Pharm.* 31, 481; 37, 1; Am Ende, *Ar. Ph.* [2] 143, 112).

**ESERINE**  $C_5H_7N_3O_2$ . *Phytostigmine*. [45°]. An alkaloid which may be extracted by moist alcohol from Calabar beans (Petit, *J. Ph.* [4] 14, 255; *C. R.* 72, 569; Hesse, *A.* 129, 115; 141, 82). Resinous; v. sol. alcohol, ether, benzene, and  $CHCl_3$ ; m. sol. water. Alkaline to litmus. Poisonous, producing contraction of the pupil. The sulphate evaporated with ammonia leaves a blue residue. Bleaching powder colours its solution red.— $B^+HIHgLi$ . [70°] (H.).

**ESSENTIAL OILS**. Oils, usually obtained from plants, which are volatile either alone or with steam. They usually contain one or more hydrocarbons such as terpenes (*q. v.*) and one or more substances containing oxygen, which sometimes separate in a solid form on cooling strongly and are then called stearoptenes, the remaining liquid being termed eleoptene (*v. also* Ours).

**ESTER**. A name applied by Gmelin to compound ethers derived from oxygenated acids to distinguish them from simple and mixed ethers.

**ETHALDEHYDE** v. **ALDEHYDE**.

**ETHANE**  $C_2H_6$  i.e.  $CH_3.CH_3$ . *Di-methyl-ethyl hydride*. Mol. v. 30. S. -0871 at 0° (Bunsen); S. (alcohol) 1.5 (Berthelot, *J.* 1867, 344). H.F.p. 25.670 (Thomsen, *J. pr.* [2] 23, 158); 28,560 (Th.); 28,000 (Dulong; Favre a. Silbermann). H.F.v. 21,510 (Thomsen); 27,400 (Th.).

**Occurrence**.—In the gases given off by natural petroleum (Smith, *A. Ch.* [5] 8, 566).

**Formation**.—1. By the action of methyl iodide upon zinc or sodium (Frankland, *C. J.* 2, 173; *A.* 71, 213; Wanklyn a. Buckeisen, *A.* 116, 329).—2. By heating propionitrile with potassium (Frankland a. Kolbe, *C. J.* 1, 60; *A.* 65, 269).—3. By the electrolysis of potassium acetate (Kolbe, *A.* 69, 279).—4. By the action of water on zinc ethyl (Frankland, *C. J.* 3, 338; *A.* 71, 203; 85, 360; 95, 53).—5. By heating ethyl iodide (9 pts.) with  $Al_2Cl_3$  (2.6 pts.) at 150° (Köhnelein, *B.* 16, 562).—6. In small quantity together with methane and  $CO_2$  by heating  $Ac_2O$  with  $BaO_2$  (Schützenberger, *B.* [2] 5, 278; Darling, *C. J.* 21, 496).—7. From  $HgEt_2$  and  $H_2SO_4$  (Schorlemmer, *A.* 132, 234).—8. From  $EtI$ , alcohol, and zinc-dust (Sabanejeff, *B.* 9, 1810).

**Preparation**.—By dropping a mixture of equal volumes of ethyl iodide and absolute alcohol upon the copper-zinc couple, the gas being passed through a scrubber containing copper-zinc, through alcoholic  $NaOH$ , through bromine-water, through caustic soda, and finally through slaked lime (Percy Frankland, *C. J.* 47, 236).

**Properties**.—Colourless gas. Burns with pale flame. With water under pressure it forms a crystalline hydrate (Villard, *C. R.* 106, 1602). The identity of ethane from  $ZnEt_2$  with that from  $KOAc$  may be shown by chlorination, both yielding ethyl chloride (Schorlemmer, *A.* 131,

76; 182, 234) or by their heats of combustion (Thomsen, *J. pr.* [2] 23, 158).

**Derivatives** v. Bromo-, Bromo-iodo-, Bromo-nitro-, Chloro-, Chloro-iodo-, Chloro-nitro-, Nitro-ethanes, &c.

**ETHANE-ARSONIC ACID** v. ARSENIC COMPOUNDS, ORGANIC.

**ETHANE-TRICARBOXYLIC ACID**

$\text{CO}_2\text{H}.\text{CH}_2.\text{CH}(\text{CO}_2\text{H})_2$ . [159°]. From the ether by conc. KOHAq. Formed also by saponifying ethane tetra-carboxylic acid and from bromosuccinic ether by successive treatment with alcoholic KCy and KOH (Orlowsky, *J. R.* 9, 278; *B.* 9, 1604). Small hard prisms (from ether). V. sol. alcohol, ether, of water, sl. sol. benzene. When melted it splits up into  $\text{CO}_2$  and succinic acid.

**Salts.**—The ammonium salt gives pps. with  $\text{BaCl}_2$  or  $\text{Pb}(\text{OAc})_2$  in the cold, and with  $\text{CaCl}_2$  or  $\text{FeCl}_3$  on warming. —  $\text{CaA}'''$ . —  $\text{Zn}_2\text{A}'''$ . 2aq. —  $\text{Ag}_2\text{A}'''$ .

**Ethyl ether**  $\text{CO}_2\text{Et}.\text{CH}_2.\text{CH}(\text{CO}_2\text{Et})_2$ . (278° uncor.). S.G.  $\frac{1}{4}$  1.083. From malonic ether, NaOEt, alcohol, and chloro-acetic ether (Bischoff, *A.* 214, 38). Oil. V. e. sol. alcohol or ether. By the action of Cl on the ether chloro-ethane-tricarboxylic ether is formed, which on boiling with HCl gives fumaric acid, and with KOH gives malic acid. By the successive action of sodium and chloro-acetic ether on the ether, the ether of propane-tetra-carboxylic acid  $(\text{CO}_2\text{H})\text{CH}_2.\text{C}(\text{CO}_2\text{H})_2.\text{CH}_2(\text{CO}_2\text{H})_2$  is formed, and this acid on heating gives  $\text{CO}_2$  and tricarballic acid  $(\text{CO}_2\text{H})\text{CH}_2.\text{CH}(\text{CO}_2\text{H})_2.\text{CH}_2(\text{CO}_2\text{H})_2$  (Bischoff, *B.* 13, 2161).

**First nitrile** v. CYANO-SUCCINIC ETHER.

**Ethane tetra-carboxylic acid**  $\text{C}_4\text{H}_4\text{O}_8$  i.e.  $(\text{CO}_2\text{H})_2\text{CH}_2.\text{CH}(\text{CO}_2\text{H})_2$ .

**Acetylene tetra-carboxylic acid.**

**Di-ethyl ether**

$\text{CO}_2\text{Et}.\text{CH}(\text{CO}_2\text{H})_2.\text{CH}(\text{CO}_2\text{H})_2.\text{CO}_2\text{Et}$ . [133°]. The potassium salt is formed as a sticky pp. by the action of KOH (36 g.) on the tetra-ethyl ether (28 g.) dissolved in alcohol (720 g.) at 0°. Plates with obtuse angles. Deliquescent, v. sol. alcohol or ether, sl. sol. chloroform or  $\text{CS}_2$ . When heated, it splits off  $\text{CO}_2$ , becoming succinic ether (Guthzeit, *A.* 214, 72). The salt  $\text{Na}_2\text{Et}_2\text{A}'''$  is converted, by di-bromo-*o*-xylene  $\text{C}_6\text{H}_4(\text{CH}_2\text{Br})_2$  into naphthalene tetra-hydride tetracarboxylic acid (Baeyer a. Perkin, *B.* 17, 449).

**Tetra-ethyl ether**  $\text{Et}_4\text{A}'''$ . [76°]. (305°). From malonic ether, chloro-malonic ether, NaOEt and alcohol (Conrad a. Bischoff, *A.* 214, 68; *B.* 13, 601; 21, 2087). Formed also by the action of iodine (1 mol.) on sodio-malonic ether (2 mols.), dissolved in absolute alcohol (Bischoff a. Raab, *B.* 17, 2781). Needles. V. sol. alcohol, ether or benzene.

**Reactions.**—1. Very stable. NaOEt and benzyl chloride do not form a benzyl derivative. 2. Heated with aqueous HCl, or with aqueous KOH, it forms  $\text{CO}_2$ , ethane tri-carboxylic acid and alcohol.

**Amide**  $\text{C}_4\text{H}_4(\text{CONH}_2)_4$ . Crystals, v. sl. sol. water. Decomposes above 230°.

**ETHANE-PHOSPHONIC ACID**  $\text{C}_2\text{H}_5.\text{PO}(\text{OH})_2$ . [44°]. From ethyl-phosphine and fuming  $\text{HNO}_3$  (Hofmann, *B.* 5, 106). Crystals, v. e. sol. water. —  $\text{Ag}_2\text{A}'$ : amorphous yellow powder.

**Chloride**  $\text{C}_2\text{H}_5.\text{POCl}_2$ . (c. 175°). Liquid (Michaelis, *B.* 13, 2174).

**ETHANE-SELENIC ACID** v. SELENIUM COMPOUNDS, ORGANIC.

**ETHANE-SULPHINIC ACID**  $\text{C}_2\text{H}_5.\text{SO}_2\text{H}$ .

**Ethyl-sulphinic acid.**

**Formation.**—1. By the action of  $\text{ZnEt}_2$  followed by water upon  $\text{SO}_2$  (Wischin, *A.* 139, 364).—2. From ethane-sulphonic chloride and zinc-dust (Pauly, *B.* 10, 941).—3. By the oxidation of sodium mercaptide  $\text{NaSEt}$ .—4. From  $\text{PbEt}_2$  and  $\text{SO}_2$  (Frankland a. Lawrance, *C. J.* 35, 246).

**Properties.**—Syrup. Gives ethane-sulphonic acid when oxidised by  $\text{HNO}_3$  (Claesson, *J. pr.* [2] 15, 222) and a compound  $\text{C}_2\text{H}_5.\text{NSO}_3$  [81°] (Zuckerschwerdt, *A.* 174, 308).

**Salts.**— $\text{NaA}'$ : crystals (from alcohol). —  $\text{BaA}'_2$  aq. —  $\text{ZnA}'_2$  aq. —  $\text{PbA}'_2$ . From  $\text{PbEt}_2$  and  $\text{SO}_2$  (Frankland a. Laurance, *B.* 12, 846). —  $\text{AgA}'$ : laminae, m. sol. water.

**Ethane di-sulphinic acid**  $\text{C}_2\text{H}_5.\text{S}_2\text{O}_4$  i.e.  $\text{C}_2\text{H}_5(\text{SO}_2\text{H})_2$ .

**Ethylene-disulphinic acid.** From ethane disulphonic chloride  $\text{C}_2\text{H}_4(\text{SO}_2\text{Cl})_2$ , zinc-dust and water (Otto, *J. pr.* [2] 36, 439). The free acid is unstable.

**Salts.**— $\text{Na}_2\text{A}''$  4aq: small laminae (from alcohol), v. e. sol. water, sl. sol. alcohol. —  $\text{ZnA}''_2$ : small plates, sl. sol. cold, v. sol. hot water.

**Di-methyl ether**  $\text{Me}_2\text{A}''$ . [190°]. **Di-methyl ethylene disulphone.** From the sodium salt and MeBr. Plates, insol. cold, sol. hot water and alcohol.

**Di-ethyl ether**  $\text{Et}_2\text{A}''$ . [137°]. **Ethylene diethyl sulphone.** From  $\text{Na}_2\text{A}''$  and  $\text{EtBr}$  (Otto, *J. pr.* [2] 36, 436). Needles. Sl. sol. ether, benzene, chloroform and  $\text{CS}_2$ , v. sol. hot alcohol. Converted by  $\text{PCl}_5$  into  $\text{C}_2\text{H}_5(\text{SO}_2\text{Cl})_2$  [91°]. Reduced in alkaline solution to ethane sulphonic acid. Aqueous KOH forms  $\text{C}_2\text{H}_5(\text{OH})(\text{SO}_2\text{Et})$  and ethane-sulphonic acid. Ammonia forms a substance [83°].

**Di-propyl ether**  $\text{Pr}_2\text{A}''$ . [155°]. From  $\text{Na}_2\text{A}''$  and  $\text{BrPr}$  (Otto). Iridescent plates.

$\text{CH}_2.\text{SO}_2.\text{CH}_2$   
**Ethylene ether**  $\text{C}_2\text{H}_4\text{A}''$  i.e.  $\text{CH}_2.\text{SO}_2.\text{CH}_2$   
From  $\text{Na}_2\text{A}''$  and ethylene bromide (Otto, *J. pr.* [2] 36, 446). Prisms, insol. ordinary solvents, m. sol. hot conc.  $\text{HNO}_3$ .

**ETHANE SULPHONIC ACID**  $\text{C}_2\text{H}_5.\text{SO}_3\text{H}$

**Ethyl sulphonic acid.**

**Formation.**—1. By the oxidation of mercaptan, of ethyl sulphocyanide, or of di-ethyl disulphide (Löwig a. Weidmann, *P.* 47, 158; 49, 329; Kopp, *A.* 35, 346; Muspratt, *C. J.* 3, 18) 2. From  $\text{K}_2\text{SO}_3$  and  $\text{EtI}$  (Strecker, *A.* 148, 90 Graebe, *A.* 146, 37).

**Properties.**—Deliquescent mass. Not acted on by Cl, but converted by  $\text{ICl}$  into  $\text{C}_2\text{H}_5.\text{Cl}.\text{SO}_3\text{H}$  and  $\text{C}_2\text{Cl}_5$  (Spring a. Winsinger, *B.* 15, 446).

**Salts.**— $\text{NaA}'$  2aq. —  $\text{NaA}'_2$  NaI (Bender, *A.* 148, 90). —  $\text{KA}'$  aq. —  $\text{CaA}'$  2aq. —  $\text{BaA}'$  aq. —  $\text{ZnA}'$  7aq. —  $\text{CuA}'$  5aq. —  $\text{HgA}'$   $\text{HgO}$  (Claesson, *A.* 148, 90). —  $\text{PbA}'$  aq. —  $\text{AgA}'$ .

**Methyl ether**  $\text{MeA}'$ . (c. 199°). From ethane sulphonic chloride and NaOMe (Carius, *J. pr.* [2] 2, 262).

**Ethyl ether**  $\text{EtA}'$ . Mol. w. 188. (218 cor.). S.G.  $\frac{1}{4}$  1.1712;  $\frac{1}{2}$  1.1452.  $B_m$  90.79. Free

$C_2H_5SO_2Cl$  and  $NaOEt$  (C.); or from  $EtI$  and  $Ag_2SO_4$  (Kurbatoff, A. 178, 7; Nasini, B. 15, 2884; G. 13, 804).

**Chloride**  $C_2H_5SO_2Cl$ . (178° cor.). S.G. 1.357. From the sodium salt and  $PCl_5$  (Gerhardt a. Chanocel, C. R. 35, 691). Also from di-ethyl sulphoxide and phlorine in presence of water (S. a. W.).  $PCl_5$  decomposes it into  $EtCl$  and  $SOCl_2$ .

**Amide**  $C_2H_5SO_2NH_2$ . [58°]. Silky needles or long prisms (from ether). Sol. water, alcohol and ether (James, C. J. 43, 43).

**Methylamide**  $C_2H_5SO_2NHMe$ . (276°). S.G. 1.216. From the chloride and methylamine, both being dissolved in cold ether (Franchimont a. Klobbie, R. T. C. 5, 274). Liquid, miscible with water. When poured into 5 pts. of fuming  $HNO_3$  (S.G. 1.6) it forms a nitramide  $C_2H_5SO_2N(NO_2)Me$  [11°], a liquid which deflagrates at 100° and is sl. sol. cold water. The nitramide is volatile with steam.

**Di-methyl-amide**  $C_2H_5SO_2NMe_2$ . (240°). S.G. 1.146. Liquid, miscible with water. When poured into 5 vols. of  $HNO_3$  (S.G. 1.5) it gives di-methyl-nitramine  $NMe_2NO_2$ .

**Ethylamide**  $C_2H_5SO_2NHEt$ . (272°). S.G. 1.154. Liquid, miscible with water, sol. ether.  $HNO_3$  (S.G. 1.5) gives the nitramide  $C_2H_5SO_2NEtNO_2$  [20°], a crystalline substance sl. sol. cold water, volatile with steam.

**Diethylamide**  $C_2H_5SO_2NEt_2$ . (254°). S.G. 1.080. Liquid, with characteristic odour, sol. ether, sol. water, but not miscible therewith. Fuming  $HNO_3$  (S.G. 1.6) gives  $C_2H_5SO_2NEt_2NO_2$  (F. a. K.).

**s-Ethane-disulphonic acid**  
 $SO_3H.CH_2.CH_2.SO_3H$ . *Ethylene disulphonic acid*. [94°] (when anhydrous).

**Formation**.—1. Together with sulphopropionic acid and  $CO_2$ , by heating propionamide or propionitrile with fuming  $H_2SO_4$  (Buckton a. Hofmann, C. J. 9, 250; A. 100, 129).—2. By the action of fuming nitric acid upon ethylene thiocarbonate  $C_2H_4CS$  (Husemann, A. 126, 269) or upon  $C_2H_4(SH)_2$ .—3. From nitro-ethane and fuming  $H_2SO_4$  (Meyer a. Wurster, B. 11, 1168).

**Properties**.—Deliquescent mass of radiating crystals (containing aq). Potash-fusion gives acetylene (Berthelot, Z. 1863, 682).

**Salts**.— $(NH_4)_2A'$ : long monoclinic prisms.— $K_2A''$ : thick, four-sided, monoclinic prisms. S. 38 at 17°.— $KHA''$  1:1 aq: hard crystalline crusts.— $Na_2A''$  2aq. S. 0.23 at 21° (Guarreschi, G. 9, 88).— $Ag_2A''$ : thin monoclinic tables.— $AgHA''$  1:2 aq.— $BaA''$  aq: stellate groups of six-sided tablets (B. a. H.).— $BaA''$ : monoclinic prisms; ppd. by alcohol, or from water. S. 2.85 at 17° (G.).— $BaA''$  2aq: trimetric octahedra (Husemann).— $CaA''$ — $CuA''$  4aq: monoclinic light-blue prisms.— $PbA''$  1:1 aq: easily soluble crystals.— $PbA''$  2aq.— $MgA''$  6aq.— $HgA''$  6aq: long thin monoclinic prisms.— $Hg_2A''$  aq: white crusts, which separate on warming into an acid and a basic salt.— $ZnA''$  6aq: nacreous monoclinic tables.

**Chloride**  $C_2H_5(SO_2Cl)_2$ . [91°]. Needles (from ether). Boiling alcohol decomposes it, giving off  $SO_2$  and  $EtCl$  (Königs, B. 7, 1163).

**s-Ethane disulphonic acid**  $CH_3CH(SO_3H)_2$ . *Ethylidene disulphonic acid*. Obtained by oxidising thio-aldehyde ( $C_2H_4S$ ), or thialdine by

$KMnO_4$  (Guarreschi, G. 9, 75; A. 222, 802). Syrup, v. sol. water and alcohol.

**Salts**.— $Na_2A''$  aq: tables, nearly insol. alcohol.— $K_2A''$  2aq: prisms (from water).— $K_2A''$ : needles, ppd. by adding alcohol to its aqueous solution. S. 64 at 17°.— $MgA''$  5aq.— $CaA''$ — $BaA''$  3aq: tables (from water). S. (of  $BaA''$ ) 11 at 17°.— $BaA''$  3:1 aq: ppd. by alcohol.— $CaA''$  2aq.— $CuA''$  aq.— $Ag_2A''$  aq: slender needles.

**Ethylether**  $Et_2A''$ . From  $Ag_2A''$  and  $EtI$  (Manzelius, B. 21, 1551). Reddish oil, insol. alkalis, v. sol. alcohol and ether. With  $NaOEt$  it gives  $CH_3ONa(SO_3Et)_2$ , whence  $EtI$  gives butane disulphonic ether.

**Ethane-tri-sulphonic acid**  
 $CH_3(SO_3H).CH(SO_3H)_2$ . *Ethenyl-tri-sulphonic acid*. Formed by boiling tri-chloro-ethane (chloro-ethylene dichloride) with a saturated aqueous solution of neutral ammonium sulphite (Monari, B. 18, 1346). Large hexagonal tables. V. sol. water and alcohol. Strongly acid.

**Salts**.— $A'''Na_2$  4aq: large six-sided tables.— $A'''(NH_4)_2$ : large prisms.— $A'''Ba_2$  5:1 aq: octahedral crystals, somewhat sol. water.

#### ETHANE-THIO-SULPHONIC ACID

$C_2H_5SO_2SH$ . Prepared by the action of  $K_2S$  on ethane-sulphonic chloride (Spring, B. 7, 1182).

**Ethyl ether**  $C_2H_5SO_2SCH_3$ . *Ethyl-disulphozide*. (130°–140°). S.G. 1.24. Prepared by the action of  $C_2H_5Br$  on the potassium salt (Otto, B. 15, 122; 11, 2073). Formed also by heating mercaptan or  $Et_2S_2$  with nitric acid (S.G. 1.23) (Löwig a. Weidmann, A. 35, 343; Lukaschewitch, Z. 1868, 641). Oil, smelling of onions; volatile with steam; v. sol. alcohol and ether, insol. ligroin. Further oxidation by  $HNO_3$  converts it into ethane-sulphonic acid. Zinc and dilute  $H_2SO_4$  reduce it to mercaptan. Aqueous potash forms  $Et_2S_2$ , ethane sulphonic acid, and ethane sulphinic acid (Pauly a. Otto, B. 11, 2073).

**ETHENYL**. The trivalent radicle  $CH_2Cl$ . Vinyl is the name given to the isomeric monovalent radicle  $CH_2CH$ .

#### ETHENYL-AMIDINE v. ACETAMIDINE.

**ETHENYL-AMIDO-BENZAMIDE v. Oxy-methyl-quinazoline.**

#### ETHENYL TRI-AMIDO-BENZENE

$C_6H_3(NH_2)(N_2HC_2H_5)_3$ . The hydrochloride of this base  $B'H_3Cl$  1:1 aq, formed by the action of  $HCl$  on its acetyl derivative, crystallises in easily soluble lustrous crystals.

#### Acetyl derivative

$C_6H_3(NHAc)(N_2HC_2H_5)_3$  2aq. [85°–90°] (above 350°). From tri-amido-benzene and  $Ac_2O$  (Sal-kowski a. Rudolph, B. 10, 1692). Geodes of prisms (from water); v. sl. sol. cold water.

**Ethenyl-tetra-amido-benzene**  $C_6H_2N_4$ , i.e.

$C_6H_2(NH_2)_2\langle\begin{smallmatrix} NH \\ N \end{smallmatrix}\rangle CMe$  [1:2:3:4]. Formed by reduction of nitro-ethenyl-tri-amido-benzene. The free base is at once oxidised by the air to brown bodies. With quinones it forms quinoxalines.— $B'H_3Cl_2$ : colourless plates. The picrate forms sparingly soluble yellow needles (Nietzki a. Hagenbach, B. 20, 889).

**Di-ethenyl-tetra-amido-benzene**  $C_6H_2N_4$ , i.e.  $C_6H_2\langle\begin{smallmatrix} NH \\ N \end{smallmatrix}\rangle CMe$ , [1:2:3:4]. [210°]. Long colourless needles (containing aq). V. sol. alco-

hol and hot water, sl. sol. cold water, nearly insol. ether. Formed by reduction of di-nitro-di-acetyl-*p*-phenylene-diamine with tin and HCl. It is a very stable body and cannot be saponified.

**Salts.**— $B''H_2Cl_2$  aq: colourless soluble crystals.— $B''H_2Cl_2PtCl_3$  2aq: long yellow needles.— $B''H_2SO_4$  aq: colourless needles.—Picrate  $B''C_6H_3(NO_2)_3OH$ : yellow needles (Nietzki a. Hagenbach, *B.* 20, 329).

**Di-ethenyl-tetra-amido-benzene**  $C_{12}H_8N_4$ , i.e.  $C_6H_2(\text{N} \begin{smallmatrix} \text{NH} \\ \text{CMe} \end{smallmatrix})_4$ , [1:2:4:5]. (above 360°).

Colourless needles. Formed by reduction of di-acetyl-di-nitro-*m*-phenylene-diamine.

**Salts.**— $B''H_2SO_4$ : colourless needles.— $B''H_2Cl_2PtCl_3$  4aq: yellow needles (Nietzki a. Hagenbach, *B.* 20, 336).

#### ETHENYL-DI-AMIDO-BENZOIC ACID

$C_8H_4(CO_2H)(\text{N} \begin{smallmatrix} \text{NH} \\ \text{CCH}_3 \end{smallmatrix})_2$ , [1:3:4]. *Ethenyl-o-phenylene-diamine carboxylic acid*. [*c.* 302°]. Formed by reduction of *m*-nitro-*p*-acetamidobenzoic acid [221°], or of *p*-nitro-*m*-acetamidobenzoic acid [206°], with tin and acetic acid (Kaiser, *B.* 18, 2941). White needles (containing aq). V. sol. hot acetic acid, less sol. hot alcohol, nearly insol. ether, acetone, benzene, and chloroform.

**Salts.**— $A'K$ : very soluble microscopic needles.— $A'H_2HCl$  ½aq: easily soluble fine white needles.— $(A'H_2HCl)PtCl_3$  2aq: thick yellow needles, sol. hot, sl. sol. cold, water.

#### ETHENYL-AMIDO-*p*-CRESOL

$[1\frac{1}{2}] C_8H_7(OH)(\text{N} \begin{smallmatrix} \text{NH} \\ \text{CCH}_3 \end{smallmatrix})$ , (219° uncor.). Formed by boiling the hydrochloride of amido-*p*-cresol with acetic anhydride and sodium acetate (Nölting a. Kohn, *B.* 17, 361). Liquid. Sol. alcohol, ether, and aqueous acids, v. sl. sol. water.

**Salts.**— $B'HCl$ : very soluble white crystalline powder.— $B''H_2Cl_2PtCl_3$ : yellow powder, sol. water and alcohol.

**ETHENYL-TRI-AMIDO- $\psi$ -CUMENE** v. AMIDO- $\psi$ -CUMYLENE-ACETAMIDINE.

#### ETHENYL-TRI-AMIDO-NAPHTHALENE

$C_{12}H_{11}N_3$ , i.e.  $NH_2 \cdot C_{10}H_7(\text{N} \begin{smallmatrix} \text{NH} \\ \text{CCH}_3 \end{smallmatrix})_3$ . From the acetyl derivative of di-nitro-( $\alpha$ )-naphthylamine by reduction with tin and HCl (Meldola a. Streatfeild, *C. J.* 51, 692). The free base is extremely soluble in water, and is rapidly oxidised by exposure of its solution to the air. Aqueous solutions of its salts are oxidised by air.

**Salts.**— $B''H_2SO_4$  ½aq.— $B''H_2Cl_2$  1½aq: stellate aggregates of thick stumpy needles.— $B''H_2Cl_2$  ½aq: long white needles.— $B''H_2PtCl_3$ — $B''H_2ZnCl_2$  aq.

#### ETHENYL-( $\alpha$ )-AMIDO-( $\beta$ )-NAPHTHOL

$C_{10}H_7(\text{N} \begin{smallmatrix} \text{NH} \\ \text{CCH}_3 \end{smallmatrix})$ . Formed by heating acetyl-( $\alpha$ )-amido-( $\beta$ )-naphthol  $C_{10}H_7(NHAc)OH$ — $B''H_2Cl_2PtCl_3$  2aq: yellow crystalline powder (Böttcher, *B.* 16, 1939; *C. C.* 1884, 898).

**ETHENYL-( $\alpha$ )-AMIDO-NAPHTHYL-MERCAPTAN**  $C_{10}H_7(\text{N} \begin{smallmatrix} \text{NH} \\ \text{CCH}_3 \end{smallmatrix})SH$ , [95°] (*J.*). Formed, together with diacetyl-amido-naphthyl mercaptan, by heating acetyl-( $\alpha$ )-naphthylamine with sulphur (Hofmann, *B.* 20, 1800). Obtained by oxidation of the thioacetyl derivative of ( $\alpha$ )-

naphthylamine  $C_{10}H_7 \cdot N \cdot C(SH) \cdot CH_3$  with potassium ferricyanide: the yield is 50 p.c. of theoretical (Jacobsen, *B.* 20, 1898). Colourless prismatic crystals (from alcohol) (*J.*). Insol. water: volatile with steam (*H.*). Gives phthalic acid when oxidised by  $KMnO_4$  (Jacobsen, *B.* 21, 2824).

**ETHENYL-AMIDO-PHENOL** v. AMIDO-PHENOL, vol. i. p. 170.

#### ETHENYL-AMIDO-PHENYL MERCAPTAN

$C_8H_7NS$  i.e.  $C_6H_5(\text{N} \begin{smallmatrix} \text{NH} \\ \text{CCH}_3 \end{smallmatrix})SH$ , (239°).

**Formation.**—1. By heating *o*-amido-phenyl mercaptan with aldehyde, acetic anhydride, acetonitrile, or acetyl chloride (Hofmann, *B.* 18, 21, 1286).—2. By oxidation of a cold dilute solution of thioacetanilide in an excess of aqueous NaOH by means of  $K_2FeC_4$ ; the yield is 35 p.c. (Jacobsen, *B.* 19, 1072).

**Properties.**—Colourless oil.

When an alkyl-iodide of this base is mixed with an alkyl-iodide of methenyl-*o*-amido-phenyl mercaptan, and the aqueous solution boiled with  $NH_3$ , colouring-matters are obtained analogous to the cyanines (v. METHENYL-*o*-AMIDO-PHENYL-MERCAPTAN). In this and other respects the base shows considerable analogy with methyl-quinoline (Hofmann, *B.* 20, 2262). Phthalic anhydride and  $ZnCl_2$  at 190° give rise to the compound  $C_8H_4(\text{N} \begin{smallmatrix} \text{NH} \\ \text{CCH}_3 \end{smallmatrix})_2(C_2O_2) \cdot C_6H_5$  (above 320°) (Jacobsen, *B.* 21, 2624).

**Salt.**— $B''H_2PtCl_3$ : needles or prisms.

#### ETHENYL-TRI-AMIDO-TOLUENE

$C_9H_7(CH_3)(\text{N} \begin{smallmatrix} \text{NH} \\ \text{CCH}_3 \end{smallmatrix})_3$ , [1:5:3:4]. [*c.* 100°].

**Preparation.**—Di-nitro-acetyl-*p*-toluidine (1 pt.) is reduced with tin (5 pts.) and conc. HCl (10 pts.) and boiled for five or six hours; on concentration of the solution the hydrochloride crystallises out.

**Properties.**—Transparent monoclinic crystals (containing aq), *a:b:c* = 1.5813:1.0:0.8216. V. sol. hot water and alcohol, sl. sol. ether and benzene, nearly insol. cold water.

#### Acetyl derivative

$C_9H_7Me(NHAc)_3 \cdot N_3$ , [166°]; white concentric needles. Formed by the action of acetic anhydride upon ethenyl-tri-amido-toluene, or upon *p*-acetyl-tri-amido-toluene. By boiling with conc. HCl it is converted into ethenyl-tri-amido-toluene (Niemcewiczski, *B.* 19, 719).

#### ETHENYL-AMIDO-TOLYL MERCAPTAN

$C_9H_7(CH_3)(\text{N} \begin{smallmatrix} \text{NH} \\ \text{CCH}_3 \end{smallmatrix})SH$ . Prepared by heating *p*-amido-*m*-tolyl mercaptan with acetic anhydride.—( $B'HCl$ ) $PtCl_3$  (Hess, *B.* 14, 493).

#### ETHENYL-AMIDOXIM $C_6H_5N_2O$ i.e.

$CH_3 \cdot C(NH_2) \cdot NOH$ . *Acetamidoxim*, [135°]. Long, pointed crystals. V. sol. water and alcohol.  $FeCl_3$  gives a deep red colour. On warming with water it decomposes into hydroxylamine and acetamide. The hydrochloride ( $B'HCl$ ) is prepared by the action of hydroxylamine on acetonitrile in aqueous alcoholic solution at 30°–40°. It crystallises in white glistening scales [140°]; v. sol. water and alcohol, insol. ether, benzene, and ligroin. With  $NaNO_2$  it yields acetamide and  $N_2O$ . With  $CuSO_4$  and  $NH_3$  it gives a bluish-green pp. of the formula  $C_6H_5N_2O \cdot Cu(OH)_2$ .

*Benzyl ether*  $\text{CH}_2\text{C}(\text{NH}_2)\text{N}(\text{OCH}_2\text{Ph})$ : yellow oily liquid; v. sol. alcohol, ether and benzene, nearly insol. water. Its hydrochloride ( $\text{BHCl}$ ) forms silky white scales [ $163^\circ$ ], v. sol. water and alcohol (Nordmann, *B.* 17, 2746).

**ETHENYL-AMIDO-XYLYL-MERCAPTAN**  
 $\text{C}_6\text{H}_4\text{Me}_2\text{N} \begin{smallmatrix} \text{NH} \\ \text{S} \end{smallmatrix} \text{CMe}$ . Oil. From thio-acetyl-xylylidine and alkaline  $\text{K}_2\text{FeO}_4$  (Gudeman, *B.* 21, 2549).

**ETHENYL-AZOXIM** v. Azoxims.

**ETHENYL-BROMO-( $\alpha\beta$ )-NAPHTHYLENE-DIAMINE** v. Bromo-ethenyl-naphthylene-diamine.

**TRI-ETHENYL-BUTYRIC ACID** v. Deconois acid.

**ETHENYL TRICARBOXYLIC ACID** v. Ethane tricarboxylic acid.

**ETHENYL-TRI-METHYLENE-DIAMINE**  
 $\text{C}_2\text{H}_4\text{N}_2$ , i.e.  $\text{CH}_2 \begin{smallmatrix} \text{CH}_2\text{NH} \\ \text{CH}_2\text{N} \end{smallmatrix} \text{CMe}$ . Obtained as hydrochloride on treating tri-methylene-diamine hydrate with  $\text{Ac}_2\text{O}$ , distilling off  $\text{HOAc}$  and warming in an atmosphere of  $\text{HCl}$  (Hofmann, *B.* 21, 2336). The base is a brown oil.

Salts.— $\text{B}^+\text{H}_2\text{PtCl}_6$ : large rhombic crystals, v. sol. water.— $\text{B}^+\text{HClAuCl}_4$ : needles.

**ETHENYL-(1:2)-NAPHTHYLENE-DIAMINE**  $\text{C}_{10}\text{H}_8 \begin{smallmatrix} \text{NH} \\ \text{N} \end{smallmatrix} \text{CCH}_3$ . Naphthylene-acetamidine. Formed by reduction of the acetyl derivative of (1:2)-nitro-( $\alpha$ )-naphthylamine with tin and  $\text{HCl}$  (Lellmann a. Remy, *B.* 19, 799). Formed also by reducing bromo-ethenyl-naphthylene-diamine [ $229^\circ$ ] in alcoholic solution by sodium amalgam (Prager, *B.* 18, 2161), and by reducing acetyl-nitro-( $\beta$ )-naphthylamine with  $\text{SnCl}_2$  (Jacobsen, *B.* 14, 1794).

Salts.— $\text{B}^+\text{HCl}$ : small soluble colourless needles.— $\text{B}^+\text{H}_2\text{PtCl}_6$ : yellow crystalline pp.— $\text{B}^+\text{H}_2\text{SO}_4$  [ $269^\circ$ ]; white powder.— $\text{B}^+\text{C}_6\text{H}_4(\text{NO}_2)_2\text{OH}$  [ $242^\circ$ ]; small yellow needles or plates.

**ETHENYL-TRI-PHENOL** v. Tri-oxy-tri-phenyl-ethane.

**ETHENYL-DI-PHENYL-AMIDINE** v. Di-phenyl-acetamidine.

**ETHENYL-PHENYL-AMIDOXIM**  
 $\text{CH}_2\text{C}(\text{NHPh})\text{NOH}$ . Ethenyl-anilidoxim. [ $121^\circ$ ]. Formed by heating ethenyl-amidoxim with aniline (Nordmann, *B.* 17, 2752). Large yellow glistening plates. Sol. alcohol, ether, benzene, and hot water, nearly insol. cold water.  $\text{FeCl}_3$  colours it deep-violet to olive-green.

**ETHENYL-DI-PHENYL-DIAMINE** v. Di-phenyl-acetamidine.

**ETHENYL-PHENYLENE DIAMINE**

$\text{C}_6\text{H}_4\text{N}_2$ , i.e.  $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{NH} \\ \text{N} \end{smallmatrix} \text{CCH}_3$ . [ $170^\circ$ ] (H); [ $175^\circ$ ] (L). Formed by reducing acetyl-o-nitro-aniline or its bromo-derivative with zinc and glacial acetic acid (Hübner, *A.* 209, 352; *B.* 8, 471). Formed also by boiling o-phenylene-diamine with glacial acetic acid (Ladenburg, *B.* 8, 677). Needles or leaflets. The hydrochloride, sulphate and nitrate form colourless needles.— $\text{B}^+\text{HCl}$ ,  $\text{B}^+\text{H}_2\text{SO}_4$ ,  $\text{B}^+\text{H}_2\text{SO}_4$  and  $\text{B}^+\text{HNO}_3$ .— $\text{B}^+\text{H}_2\text{PtCl}_6$ , sq.

Ethenyl-phenylene-diamine carboxylic acid v. Ethenyl-di-amido-benzoic acid.

## ETHENYL-PROPYLENE DIAMINE

$\text{C}_2\text{H}_5 \begin{smallmatrix} \text{N} \\ \text{NH} \end{smallmatrix} \text{CMe}$ . From di-acetyl-propylene-diamine by heating a current of dry  $\text{HCl}$  (Hofmann, *B.* 21, 2332).— $\text{B}^+\text{H}_2\text{PtCl}_6$ : trimetric crystals, extremely sol. water.— $\text{B}^+\text{H}_2\text{AuCl}_4$ : small needles.

**ETHENYL-TRI-SULPHONIC ACID** v. Ethane-tri-sulphonic acid.

## ETHENYL-TOLYLENE-o-DIAMINE

$\text{C}_6\text{H}_4\text{Me} \begin{smallmatrix} \text{NH} \\ \text{N} \end{smallmatrix} \text{CCH}_3$ . [ $199^\circ$ ]. Formed with elimination of  $\text{AcOEt}$  and  $\text{H}_2\text{O}$ , by heating tolylene-o-diamine with aceto-acetic ether (Ladenburg a. Rugheimer, *B.* 12, 951; Witt, *B.* 19, 2977). It gives a nitro-derivative [ $202^\circ$ ].

**ETHER**  $\text{C}_2\text{H}_5\text{O}$  i.e.  $\text{Et}_2\text{O}$ . Di-ethyl oxide. Ethylether. Sulphuric ether. [ $-117^\circ$ ] (Olszewsky, *M.* 5, 128). Mol. w. 74. ( $34.6^\circ$ ) (Schiff, *A.* 220, 332). S.G.  $3^\circ$  7157 (Brühl);  $15^\circ$  7201;  $25^\circ$  7099 (Perkin, *C. J.* 45, 474). S.  $8.3$  at  $17.5^\circ$ . S.V. 106.4 (Ramsay); 106.24 (S.); 106.1 (P.). C.E. ( $0^\circ$ – $10^\circ$ ) 00152 (Dobrinier, *A.* 243, 20). M.M. 4.777 at  $20^\circ$  (P.).  $\mu_s$  1.3572 (B.; cf. Oudemans jun. *R. T. C.* 4, 269).  $R_\infty$  35.53 (B.). H.F.p. 70.040 (Th.); 53,000 (Berthelot). H.F.v. 67,430 (Th.).

Critical temperature  $194^\circ$  (Ramsay a. Young, *Pr.* 40, 381; *P. M.* [5] 24, 196).

Effect of dissolved substances on the vapour pressure of ether: Raoult, *C. R.* 104, 976.

Coefficient of Compressibility 0.00183 at  $21.5^\circ$  (Isambert, *C. R.* 105, 375).

**Formation**.—1. From alcohol by treatment with  $\text{H}_2\text{SO}_4$  (Valerius Cordius, a.d. 1540; Frobenius; Valentin Rose, *Scher. J.* 4, 255; Saussure, *A. Ch.* 89, 273; Dumas a. Boullay, *A. Ch.* [2] 36, 294). Formed also from alcohol by treatment with phosphoric acid (Boullay, *A. Ch.* 62, 192), with arsenic acid (Boullay, *A. Ch.* 78, 281), with  $\text{BF}_3$  (Deslosses, *A. Ch.* [2] 16, 72), with  $\text{ZnCl}_2$  (Masson, *A.* 31, 63) or with  $\text{SnCl}_4$  (Kuhlmann, *A.* 33, 97, 192).—2. By the action of ethyl iodide (bromide, or chloride) on sodium (or potassium) ethylate (Williamson, *C. J.* 4, 106).—3. From  $\text{EtI}$  and dry  $\text{Ag}_2\text{O}$ .—4. By heating alcohol with  $\text{EtBr}$  or  $\text{EtI}$  at  $200^\circ$  (Reynoso, *A. Ch.* [3] 48, 385).—5. By heating  $\text{EtBr}$  or  $\text{EtI}$  with water at  $150^\circ$ – $200^\circ$  (R.).—6. By heating alcohol with  $\text{HCl}$ ,  $\text{HBr}$ ,  $\text{HI}$ , or chlorides of Mn, Co, Ni, Cd, Zn, Si, Fe, Hg, Ca, Sr, &c. In the case of  $\text{CaCl}_2$  a temperature of  $300^\circ$  is required (Berthelot, *A.* 83, 104).  $\text{HgI}_2$  and  $\text{SiF}_4$  also etherify (R.).—7. Alcohol is also etherified by heating with the sulphates of Mg, Zn, Cd, Fe, Co, Al, and with alums (Reynoso).—8. By heating  $\text{EtI}$  with  $\text{Na}_2\text{O}$  at  $180^\circ$  (Greene, *C. R.* 86, 1141).—9. By heating alcohol with  $\text{Et}_2\text{SO}_4$  (Erlenmeyer, *A.* 142, 373).

**Preparation**.—A mixture of alcohol of 90 p.c. (5 pts.) and conc.  $\text{H}_2\text{SO}_4$  (9 pts.) is boiled, and alcohol (30 pts.) is allowed to run in continuously through a tube, dipping under the surface of the liquid at such a rate that the liquid boils constantly at  $140^\circ$  (Boullay, *J. Ph.* 1, 97). The distillate separates into two layers, the upper consisting of ether containing alcohol and water in solution, the lower of water containing alcohol and ether in solution; but towards the latter part of the distillation, when the sulphuric acid has become weaker, more alcohol passes

over unchanged, and the separation of the ether no longer takes place. The ether is freed from sulphurous and acetic acids by agitation with milk of lime, and is finally rectified. The yield is about 90 p.c. of the theoretical. The amount of olefant gas formed during the process may be very greatly diminished by keeping the mixture at 180° instead of 140° (Soubeiran, *J. Ph.* [3] 16, 321). Ether may be freed from traces of alcohol and water by fused calcium chloride; or it may be shaken several times with water, and finally dried over quicklime.

**Properties.**—Colourless, very mobile liquid, with characteristic odour and burning taste. Very inflammable, burning with a luminous flame; its vapour forms an explosive mixture with air. When inhaled it produces insensibility. 35 pts. of ether dissolve 1 pt. of water. It mixes with alcohol, CS<sub>2</sub>, chloroform, acetone, and many essential oils; in the latter case presence of water or alcohol is indicated by turbidity (Blanchet, *A. J.* 7, 157). Wet ether gives turbidity with CS<sub>2</sub>. It dissolves iodine and bromine and small quantities of sulphur and phosphorus. It also dissolves AuCl<sub>3</sub>, FeCl<sub>3</sub>, HgCl<sub>2</sub>, Hg(NO<sub>3</sub>)<sub>2</sub>, fats, resins, and many other organic bodies. Strong aqueous HCl dissolves ether with evolution of heat, apparently forming an unstable compound. By rapidly evaporating wet ether Tanret (*C. R.* 86, 765) obtained a cryohydrate C<sub>4</sub>H<sub>10</sub>O 2aq [-3.6°].

**Reactions.**—1. The vapour of ether passed through a red-hot tube produces C<sub>2</sub>H<sub>4</sub>, water, CO, and aldehyde.—2. When a mixture of ether-vapour and air comes in contact with platinum black, heated platinum-sponge, or other bodies heated not quite to redness, it undergoes slow and imperfect combustion, emitting a pale light, and forming aldehyde, acetic, and formic acids, CO<sub>2</sub>, water, &c. Oxidised by a red-hot platinum spiral it gives formic acid, acetic acid, aldehyde, acetal, formic aldehyde and trimetric prisms of C<sub>11</sub>H<sub>22</sub>O<sub>4</sub> [51°]. These prisms are soluble in water, alcohol, ether, or chloroform, and are decomposed by alkalis into formic aldehyde and formic acid. The compound liberates I from KI solution, and reduces PbO<sub>2</sub>, and appears, therefore, to be a derivative of H<sub>2</sub>O<sub>2</sub> (Legler, *A.* 217, 381).—3. Dry ozonised oxygen acts violently, forming acetic acid, oxalic acid, H<sub>2</sub>O<sub>2</sub>, and a little formic acid (A. W. Wright, *Am. S.* [3] 7, 184). According to Berthelot (*Bt.* [2] 36, 72) syrupy Et<sub>2</sub>O<sub>2</sub> is formed in this reaction.—4. Sulphuric acid at 120° forms ethyl-sulphuric acid EtHSO<sub>4</sub>. When ether is boiled with sulphuric acid the temperature rises from 130° to 180°; SO<sub>2</sub> and Et<sub>2</sub>SO<sub>3</sub> pass over while isethionic acid, ethionio acid, &c., remain in the retort.—5. The product of the action of SO<sub>2</sub> separates into an aqueous and a brown ethereal layer. The former contains ethionio acid, which, on boiling, changes to isethionic acid. The latter consists of di-ethyl sulphate (84 p.c.), ethyl ethionate (12 p.c.), and ethyl methionate CH<sub>3</sub>(SO<sub>2</sub>Et)<sub>2</sub> (4 p.c.) (R. Hübner, *A.* 228, 207). The reaction may perhaps be represented as follows:—

6. Hot nitric acid forms CO<sub>2</sub>, acetic acid, and oxalic acid. CrO<sub>3</sub> also oxidises it to acetic acid.—7. HCl gas forms ethyl chloride.—8. Dry chlorine forms di-, tetra-, and deca-, chloro-diethyl oxides, aldehyde, chloral, EtCl, &c. In presence of water acetic acid and other products of oxidation are formed.—9. A solution of bromine in ether becomes colourless after a few days, EtBr, bromal, and other products being formed. According to Schützenberger (*C. R.* 75, 1511) a mixture of bromine and ether deposits in a freezing mixture crystals of (Et<sub>2</sub>O)<sub>2</sub>Br<sub>2</sub> [c. 22°]. Iodine acts but slightly on ether.—10. Sodium does not act on pure ether.—11. Heated soda-lime forms Na<sub>2</sub>CO<sub>3</sub>, hydrogen, and CH<sub>4</sub>.—12. Red-hot zinc-dust forms C<sub>2</sub>H<sub>4</sub>, water, and hydrogen (Jahn, *M.* 1, 675).

**Combinations.**—Et<sub>2</sub>O.SnCl<sub>4</sub>: volatile plates, sol. ether, decomposed by water (Kuhlmann, *A.* 33, 106, 192; Lewy, *J. pr.* 36, 146).—SnBr<sub>2</sub>.Et<sub>2</sub>O.—Et<sub>2</sub>O.SbCl<sub>5</sub> [69°]; crystalline hygroscopic powder, sol. alcohol and ether, decomposed by water and by fusion (Williams, *B.* 9, 1135).—SbBr<sub>3</sub>.Et<sub>2</sub>O.—SbBr<sub>3</sub>.2Et<sub>2</sub>O (Nickles, *C. R.* 52, 896).—BiBr<sub>3</sub>.Et<sub>2</sub>O 2aq: deliquescent prisms.—Et<sub>2</sub>O.AsBr<sub>3</sub>.—Et<sub>2</sub>O.TiCl<sub>4</sub> [42°–46°] (119°). Decomposed by water (Bedson, *C. J.* 29, 309).—(Et<sub>2</sub>O)<sub>2</sub>(TiCl<sub>4</sub>)<sub>2</sub> (B.).—(Et<sub>2</sub>O)<sub>2</sub>(PCl<sub>5</sub>)<sub>2</sub>. White plates, formed by dissolving PCl<sub>5</sub> in dry ether. Violently decomposed by water, giving ethyl-phosphoric acid, but no ether (Liebermann a. Landshoff, *B.* 18, 690).—BeCl<sub>2</sub>.2Et<sub>2</sub>O (Atterberg, *B.* 9, 856).—HgBr<sub>2</sub>.3Et<sub>2</sub>O (Nickles, *C. R.* 52, 899).—AlBr<sub>3</sub>.2Et<sub>2</sub>O.—TiCl<sub>4</sub>.Et<sub>2</sub>O.HCl aq.—TiBr<sub>3</sub>.1½Et<sub>2</sub>O (Nickles, *C. R.* 58, 537).—VdOCl<sub>5</sub>.Et<sub>2</sub>O (below 20°). Lustrous green crystals (Bedson, *C. J.* 29, 309).

**Hydroiodide** (Et<sub>2</sub>O)<sub>2</sub>.HI. An oil formed by direct combination of ether and HI (Messinger a. Engels, *B.* 21, 827). Insol. ether. Decomposed by KOH into ether and HI, and by water into ether, HI, and EtI.

**Hydrobromide** (Et<sub>2</sub>O)<sub>2</sub>.HBr. Oil. Similar to the hydroiodide.

**References.**—AMMO-, BROMO-, and CHLORO-, DI-ETHYL OXIDE.

**ETHERIFICATION.** The formation of ethers. In the most general sense etherification means the displacement by an alkyl of hydrogen attached to oxygen (or to a halogen in the case of HCl, HBr, and HI). In the narrowest sense it is applied to the making of common ether. The reactions underlying the continuous manufacture of ether may be taken as typical of all cases of etherification. Alcohol was at one time regarded as the hydrate of ether, so that in the manufacture of ether the sulphuric acid merely abstracted a molecule of water from each molecule of ether. It was pointed out by Mitscherlich that ether and water distil over in equivalent proportions (4 pts. of ether to 1 pt. of water), so that the sulphuric acid must be supposed first to take the water from the alcohol and then to give it up again. Mitscherlich and Berzelius therefore said that the sulphuric acid acted 'catalytically.' Liebig (*A.* 23, 59; 80, 129) then pointed out that on mixing alcohol and sulphuric acid hydrogen ethyl sulphate is formed, but

on distilling the mixture the quantity of hydrogen ethyl sulphate constantly diminishes as the ether passes over, and he concluded that the hydrogen ethyl sulphate must take part in the formation of ether. He assumed the first reaction to consist in the formation of hydrogen ethyl sulphate from alcohol and sulphuric acid, and that at 120°-140° that body was split up into ether, hydrogen sulphate, and  $\text{SO}_2$ , the  $\text{SO}_2$  then uniting with the water formed in the first reaction. When, however, hydrogen ethyl sulphate is heated alone it gives alcohol and not ether, although, when heated with alcohol, it does give ether. Williamson (*C. J.* 4, 106, 229; *A.* 77, 37; 81, 73; *A. Ch.* [3] 40, 98), while adopting the first of Liebig's equations, showed that the second reaction consisted in the decomposition of hydrogen ethyl sulphate by alcohol. At the same time, Williamson doubled the formula then ascribed to ether for several reasons:

(1) To bring it in accordance with Avogadro's Law.

(2) The difference between the boiling-points of alcohol and of ether (44°) is exactly that usually found between an acid and its ethyl salt.

(3) By the same methods used in preparing ordinary ether it is possible to prepare mixed ethers, such as methyl ethyl oxide  $\text{MeOEt}$ , and the boiling-points of these ethers are intermediate between those of the two corresponding simple ethers.

(4) There are other reasons for doubling the atomic weight of oxygen.

The two equations proposed by Williamson, and now universally adopted, are

That ether is alcohol in which an atom of hydrogen has been displaced by ethyl would appear probable from its formation according to the equations

The etherification of an acid by means of alcohol and  $\text{H}_2\text{SO}_4$  probably takes place for the most part according to such equations as

Etherification by alcohol and  $\text{HCl}$  being represented thus:

**ETHERS.** Ethers may be simple, mixed, or compound. Simple ethers are oxides of monovalent alkyls; the oxides of divalent radicles, such as ethylene, are not usually classed as ethers. A mixed oxide of two monovalent alkyls, such as  $\text{MeOEt}$ , is called a mixed ether. A compound ether (or ester) is a hydrogen salt in which the typical hydrogen has been displaced by an alkyl, and may therefore be regarded as an alkyl salt of an acid.

**Properties of simple and mixed ethers.** The simple and mixed ethers in general resemble ordinary ether in their properties. They are insol. water, and are not decomposed by ammonia, alkalis, sodium, dilute acids,  $\text{F}_2\text{O}_2$ , or cold  $\text{PCl}_5$ . Conc.  $\text{H}_2\text{SO}_4$  and  $\text{SO}_3$  decompose them (*v. ETHERS*). Nitric acid oxidises them to

the acids corresponding to the alkyls. If one of the alkyls is benzyl, this becomes benzoic aldehyde (Errera, *G.* 17, 198).  $\text{HI}$  forms an alcohol and an alkyl iodide; if one of the alkyls is methyl, the iodide is methyl iodide (Silva, *C. R.* 81, 823). Aluminium and iodine produce alkyl iodide, and aluminium iodoalkylate (Gladstone & Tribe, *C. J.* 80, 857). Chlorine produces products of substitution.

**Formation of compound ethers.** When an alcohol is heated with an equivalent quantity of an acid, a reaction such as:

occurs; but as soon as the products of the reaction are formed they begin to react in an inverse sense:

Thus, these two reactions occurring simultaneously an equilibrium is ultimately set up (Berthelot & Péan de Saint-Gilles, *C. R.* 53, 474; 55, 39, 210, 324; 85, 883; *A. Ch.* [3] 68, 225). When molecular mixtures of glacial acetic acid and alcohols are heated to 154° the percentage of acid etherified at the end of the first hour is called by Menschutkin the initial velocity of etherification, while the percentage etherified at the end of 120 hours is called the final limit of etherification.

The initial velocity is 55.6 for methyl alcohol, 46.7 for ethyl, propyl, and *n*-butyl alcohols, 44.9 for isobutyl alcohol, 36.1 for allyl alcohol, 38.0 for benzyl alcohol, 26.5 for isopropyl alcohol, 22.6 for *sec*-butyl alcohol, 10.6 for di-allyl carbinol, 1.4 for *tert*-butyl alcohol, and 1.5 for phenol. It will be seen that the initial velocity is greatest for primary and least for tertiary alcohols, while unsaturated alcohols etherify more slowly than saturated alcohols.

The final limit is 69.6 for methyl alcohol, about 66.8 for ethyl, propyl, butyl, and isobutyl alcohols, about 60 for allyl, benzyl, and *sec*-butyl alcohols, 10 for di-allyl carbinol, and 8.6 for phenol. The limit therefore follows in the main the same variation as the initial velocity, although in the case of primary and secondary alcohols the changes are less marked.

When the rate of etherification of various acids by the same alcohol (isobutyl alcohol was used) is examined it is found that the limit is fairly constant at 67 to 74, while the initial velocity varies from 44.4 for acetic acid to 3.5 for di-methyl-ethyl-acetic acid. Here also the normal compounds show greatest rapidity of etherification. Formic acid shows a greater initial velocity (61.7) and a lower limit (64) than any other organic acid (Menschutkin, *B.* [2] 84, 87). In the etherification of alcohols by  $\text{Ac}_2\text{O}$  the greatest velocity is shown by methyl alcohol, but in most cases the reaction is ultimately complete (Menschutkin, *C. R.* 105, 1016; *v. vol. i.* p. 737).

**Preparation of compound ethers.**—1. Volatile ethers are prepared by distilling a mixture of the alcohol, the acid (or a salt of the acid), and  $\text{H}_2\text{SO}_4$ .—2. Non-volatile ethers are prepared by passing  $\text{HCl}$  into a solution of the acid in alcohol.—3. The ethers may be prepared by treating the silver salt of the acid with ethyl iodide, and this reaction may be resorted to when neither of the preceding is available.—4. By distilling the potassium salt of an acid with potas-

sium alkyl sulphate.—5. By treating the alcohol with the chloride or anhydride of the acid.—6. By the action of HCl or  $H_2SO_4$  on a solution of the nitrile in an alcohol (Beckurts a. Otto, *C. C.* 1877, 5).—7. According to Veiel (*A.* 148, 160) compound ethers are formed by the oxidation of fatty acids by  $MnO_2$  and dilute sulphuric acid. Thus, butyric acid is said to give propyl butyrate.

**Properties of compound ethers.**—The compound ethers are almost all insol. water, but are partially saponified by heating therewith; they are saponified by heating with alkalis or alkaline earths, and by HCl or dilute  $H_2SO_4$ . Ammonia splits up compound ethers derived from organic acids into the amide and an alcohol. When a compound ether is heated with an alcohol an interchange of alkyls may take place; thus, ethyl acetate and amyl alcohol yield amyl acetate, ethyl amyl oxide, and water (Friedel a. Crafts, *A.* 130, 198; 131, 55). Compound ethers are split up by heating with dry HBr at  $100^\circ$ , forming alkyl bromide and free acid (Gal, *C. R.* 59, 1049). Aluminium and iodine react upon compound ethers of the fatty series, forming an alkyl iodide and aluminium salt (Gladstone a. Tribe, *C. J.* 30, 357). Compound ethers unite with titanium chloride, forming such compounds as  $EtOAc(TiCl_4)_2$ ,  $EtOAcTiCl_3$ , and  $(EtOAc)_3TiCl_4$  (Demarcay, *Bil.* [2] 20, 127; *C. R.* 76, 1414).

**Acid ethers.** When in polyhydric acids a part only of the typical hydrogen has been displaced by alkyls the resulting acid ether is usually very soluble in water, and readily saponified by boiling therewith.

**References.**—The particular characters of each group of compound ethers may be gathered by reference to the articles on the ethyl salts of the acids, e.g. ETHYL BROMIDE, ETHYL CHLORIDE, ETHYL PERCHLORATE, ETHYL IODIDE, ETHYL NITRATE, ETHYL NITRITE, DI-ETHYL SELENIDE, ETHYL SILICATE, ETHYL SULPHATE, DI-ETHYL SULPHIDE, ETHYL SULPHITE, ETHYL THIOSULPHATE, &c.

ETHINE or ETHINENE v. ACETYLENE.

ETHINE-DI-PHTHALYL v. DI-PHTHALYL ETHANE.

ETHIONIC ACID  $C_2H_5S_2O_3$ , i.e.  $SO_3H.CH_2CH_2.O.SO_3H$ .

**Formation.**—1. By saturating anhydrous alcohol or ether with  $SO_2$  and diluting with water (Magnus, *P.* 27, 378; 47, 514; Marchand, *P.* 32, 466).—2. Its mono-chloride is formed along with  $ClSO_2OEt$  by action of  $ClSO_3OH$  upon ethylene: (a)  $ClSO_3OH + C_2H_4 = ClSO_2OC_2H_5$ ; and then follows (b)  $ClSO_3OH + ClSO_2OEt = HCl + C_2H_5(SO_2OH)(O.SO_2Cl)$  (Claesson, *J. pr.* [2] 19, 255).—3. From  $EtSO_2$  and  $SO_2$  (Hübner, *A.* 223, 208).—4. By the action of  $H_2SO_4$  on isethionic acid  $SO_3H.CH_2CH_2OH$  in the cold (Erlenmeyer a. Carl, *N. Rep. Pharm.* 23, 428).

**Properties.**—Only known in solution, for on evaporation it splits up into  $H_2SO_4$  and isethionic acid.

**Salts.**— $K_2A^{1/2}$  aq. crystals.  $Na_2A^{1/2}$  aq.  $—BaA^{1/2}$  aq. S. 10 at  $20^\circ$ .

**Anhydride**  $\begin{matrix} CH_3O.SO_2 \\ \diagdown \quad \diagup \\ CH_3SO_2O \end{matrix}$  [80°]. Carbonyl

**sulphate.** Obtained by direct union of ethylene with  $SO_2$ ; formed also by exposing alcohol to the vapour of  $SO_2$  (Regnault, *A. Ch.* 65, 98;

Magnus, *P.* 47, 509). Deliquescent crystals; dissolves in water forming ethionio acid.

Isethionio acid v. ISETHIONIC ACID.

DIETHOXALIC ACID v. OXY-HEXOIC ACID.

ETHOXY-COMPOUNDS v. the ethyl ethers of OXY-COMPOUNDS.

ETHOXY-OXALYL CHLORIDE v. CHLOROGLYOXYLIC ETHER.

ETHYL. The radicle  $C_2H_5$  or  $CH_3CH_2$ . The ethyl derivatives of hydroxylic compounds are described under the compounds from which they are derived.

Di-ethyl v. BUTANE.

DI-ETHYL-ACETAL v. ACETAL.

DI-ETHYL-ACETAMIDINE  $C_6H_7N$ , i.e.  $CH_3C(NHEt)NEt$  (c.  $167^\circ$ ). From ethylacetamide and  $PCl_5$ , the resulting oily base  $C_6H_7ClN$ , being subsequently warmed with solid KOH (Wallach a. Hoffmann, *B.* 8, 313; *A.* 184, 108). Syrup, miscible with water, alcohol and ether. Strongly alkaline. Precipitates most metallic salts and dissolves recently ppd. alumina. Boiling alkalis split it up into acetic acid and ethylamine.

ETHYL-ACETAMIDE v. Acetyl-ETHYL-AMINE.

ETHYL-ACETANILIDE v. Acetyl-ETHYL-ANILINE.

ETHYL ACETATE v. vol. i. p. 14.

DI-ETHYL-ACETIC ACID v. HEXOIC ACID.

Ethyl-diacetic acid v. ETHYL ACETO-ACETATE, vol. i. p. 17.

ETHYL-ACETO-ACETIC ACID v. vol. i. p. 23.

ETHYL-DIACETONAMINE v. vol. i. p. 28.

ETHYL-ACETO-NITRANILIDE v. Acetyl-NITRO-ETHYL-ANILINE.

DI-ETHYL-ACETOPHENONE v. PHENYL-AMYL KETONE.

ETHYL-ACETO-PROPIONIC ACID v.  $\beta$ -ACETYL- $\alpha$ -ISO-VALENIC ACID.

ETHYL-ACETO-SUCCINIC ETHER v. ACETYL-ETHYL-SUCCINIC ETHER.

ETHYL-DI-ACETYL-ACETIC ETHER v. vol. i. p. 23.

ETHYL-ACETYL-ACETONE v. DI-METHYL-PROPYLENE DIKETONE.

DI-ETHYL-ACETYL-ACETONE v. DI-METHYL-AMYLENE DIKETONE.

ETHYL-ACETYLENE v. BUTINENE.

ETHYL-ACETYLENE-TETRA-CARBOXYLIC ACID v. BUTANE TETRA-CARBOXYLIC ETHER.

ETHYL-ESCULETTIC ACID v. Ethyl derivative of ESCULETTIC ACID.

ETHYL ALCOHOL v. ALCOHOL. Derivatives are described as BROMO-ETHYL ALCOHOL, CHLORO-ETHYL ALCOHOL, &c.

TRI-ETHYL-ALCAMINE v. OXY-TRI-ETHYL-AMINE.

ETHYL ALDEHYDE v. ALDEHYDE.

ETHYL-ALLYL v. AMYLENE.

TETRA-ETHYL-ALLYL-ALCINE v. TETRA-ETHYL-OXY-PROPYLENE-DIAMINE.

ETHYL-ALLYL-AMINE  $(C_2H_5)(C_3H_5)NH$ . (85°). Colourless ammoniacal liquid. Miscible with water. Prepared by the action of ethyl iodide on allylamine.

**Salts.**— $BHCl$ : small deliquescent plates.  $—B'H_2ClPtCl$ : orange needles (s.  $165^\circ$ ).  $—BHClPtCl$ : yellow needles [ $220^\circ$ ], formed by boiling the preceding salt with water.

— $B_2H_2SO_4$ : tables v. e. sol. water, insol. alcohol and ether. The acid oxalate forms sparingly soluble colourless plates (Binne, A. 168, 261; Liebermann a. Paal, B. 16, 525).

Di-ethyl-allyl-amine  $(C_2H_5)_2(C_3H_5)N$ . (111°). S. 5 at 18°. Colourless liquid. Its aqueous solution becomes turbid on warming. Prepared by the action of ethyl iodide on allyl-amine (Binne, A. 168, 265).

Salts.— $B'H_2Cl_2PtCl_4$ : large orange crystals [129°].— $B'HClPtCl_4$ : yellow needles [189°], formed by boiling the preceding salt with water (Liebermann a. Paal, B. 16, 526).— $B'HCl$ : very soluble crystals.

*Ethyl bromide*  $(C_2H_5)_2(C_3H_5)NBr$ . Tri-ethyl-allyl-ammonium bromide. From triethylamine and allyl bromide (Reboul, C. R. 92, 1464). Deliquescent crystals. Split up on distillation into allyl bromide, ethyl bromide, triethylamine, diethylamine, ethylene, & tri-bromo-ethane, and, probably, allylamine. From it may be prepared  $(C_2H_5)_2(C_3H_5)NCl$  and the platinum-chloride  $\{(C_2H_5)_2(C_3H_5)NCl_2\}PtCl_4$ , both crystalline.

ETHYL-ALLYL-ANILINE  $C_9H_{11}N$  i.e.  $NPhEt(C_3H_5)$ . (c. 223°). From allyl-aniline and EtI (Schiff, A. Suppl. 3, 364). Thick oil.— $B'C_2H_5O_4$ : spherical groups of small needles (from water).

ETHYL-DI-ALLYL-CARBINOL v. ENNINYL ALCOHOL.

Di-ethyl-allyl-carbinol v. OCTENYL ALCOHOL.

ETHYL-ALLYL-CYANAMIDE  $C_6H_{11}N_2$  i.e.  $ON.NEt(C_3H_5)$ . [100°]. From ethyl-allyl-thiourea,  $Pb(OH)_2$ , and KOH (Hinterberger, A. 83, 348). Needles (from ether). Insol. water, sol. alcohol and ether. Tastes bitter.— $B'_2(HgCl_2)_2$ .— $B'_2H_2PtCl_4$ .

ETHYL ALLYL OXIDE  $C_5H_9O$  i.e.  $C_2H_5.O.C_3H_5$ . *Ethyl-allyl ether*. Mol. w. 86. (67°). S.G.  $d_4^{20}$  7651.  $\mu_D$  1.3939.  $R_D = 42.2$ . Critical temperature 245° (Pawlewsky, B. 16, 2634). From allyl bromide and NaOEt, allylene being also formed (Brühl, A. 200, 178; cf. Berthelot a. De Luca, A. Ch. [3] 48, 292; Cahours a. Hofmann, A. 102, 290). Formed also by treating ethyl di-bromo-allyl oxide  $C_2H_5.O.CHBr.CH_2Br$  with sodium amalgam (Markownikoff, Z. 1865, 554). Combines with chlorine and bromine, but is not reduced by sodium amalgam. ClOH forms a compound  $C_5H_9.Cl(OH)(OEt)$  (184°).

ETHYL-ALLYL-THIO-UREA  $C_4H_9N_2S$  i.e.  $NHEt.CS.NHC_3H_5$ . From allyl thiocarbimide and ethylamine (Hinterberger, A. 83, 346; Weltzien, A. 94, 103). Syrup.— $B'_2H_2PtCl_4$ .— $B'HI$ .

Di-ethyl-allyl-thio-urea  $C_6H_{11}N_2S$  i.e.  $NEt.CS.NHC_3H_5$ . [55°]. Long prisms or needles. V. sol. alcohol and benzene, sl. sol. ligroin, insol. water. Formed by combination of allyl thiocarbimide and di-ethyl-amine (Gebhardt, B. 17, 8038).

ETHYL-ALLYL-UREA  $C_4H_9N_2O$  i.e.  $NHEt.CO.NHC_3H_5$ . From ethylamine and allyl cyanate. Prisms (Cahours a. Hofmann, A. 102, 800).

ETHYL-AMARINE v. BENZOYL ALDEHYDE, AMMONIA DERIVATIVES OF.

ETHYL-AMIDO-ACETIC ACID  $C_5H_9NO_2$  i.e.  $NHEt.CH_2.CO_2H$ . *Ethyl glyccol*. *Ethyl glycine*. [above 160°]. Prepared by prolonged

boiling of chloro-acetic acid with ethylamine (Heintz, A. 129, 27; 132, 1). Indistinct deliquescent laminae (from alcohol). Sweetish, almost metallic taste. On mixing with an aqueous solution of cyanamide there are deposited long needles of ethyl-amido-aceto-cyanamide.  $HN:C \begin{smallmatrix} < NH.CO \\ < NEt.CH_2 \end{smallmatrix}$  a homologue of creatinin; S. 9 at 25°; S. (alcohol) 1 at 25° (Duvillier, C. R. 103, 211).

Salts.— $HA'HCl$ : [c. 180°]; trimetric prisms, v. sol. water and hot alcohol.— $HA'_2H_2PtCl_4$ : large orange-red monoclinic prisms.— $HA'(HgCl_2)_2$ : small prisms (from water).— $HA'_2HgCl_2$ : syrup.— $CuA'_2$ : 4aq: prisms, v. sol. water and alcohol, insol. ether.—*Derivative*: Di-chloro-ethyl-amido-acetic ether (q. v.).

Di-ethyl-amido-acetic acid  $C_5H_9NO_2$  i.e.  $NEt_2.CH_2.CO_2H$ . Obtained by boiling diethylamine with chloro-acetic acid (Heintz, A. 140, 217; Z. [2] 5, 152). Deliquescent rhombohedral crystals; v. sol. alcohol; sublimates below 100°.— $CuA'_2$ : 4aq: small blue prisms.— $HA'_2H_2PtCl_4$ : orange-red crystals.

*Ethyl ether*  $NEt_2.CH_2.CO_2Et$ . (174° uncor.). S.G.  $d_4^{25}$  910. From silver-glyccol and EtI (Kraut, A. 182, 172; 210, 317). Alkaline liquid.— $B'_2H_2PtCl_4$ : short monoclinic crystals.— $B'_2H_2BiI_3$ : slender red needles.

*Ethyl-hydroxide*. *Anhydride*.

$C_5H_9NO_2$  i.e.  $NEt_2 \begin{smallmatrix} < CH_2 \\ < O \end{smallmatrix} CO$ . 'Triethyl glyccol' (210°). Prepared by heating  $NEt_2$  with chloro-acetic ether, boiling the product with baryta water, and heating the resulting ethyl-chloride with silver oxide (Kraut, A. 182, 172). Formed also from  $NEt_2$  and chloro-acetic acid (Hofmann, Pr. 11, 525; Brühl, B. 8, 479; A. 177, 201). Deliquescent crystalline mass; partly decomposed by distillation giving off  $NEt_2$ .

*Ethyl-chloride*  $NEt_2.Cl.CH_2.CO_2H$ . From  $NEt_2$  and chloro-acetic acid. Not decomposed by boiling potash or baryta water.

Salts.— $(NEt_2.Cl.CH_2.CO_2H).PtCl_4$ : 2aq: monoclinic prisms.— $(NEt_2.Cl.CH_2.CO_2H).AuCl_4$ .

*Ethyl-iodide*  $NEt_2.I.CH_2.CO_2H$ : orange hair-like crystals.— $(NEt_2.I.CH_2.CO_2H).BiI_3$ : orange tables.

*Ethyl-nitrate*  $NEt_2(NO_3).CH_2.CO_2H$ : needles, v. e. sol. water.

*Ethyl ether of the ethyl-chloride*  $NEt_2.Cl.CH_2.CO_2Et$ . From triethylamine and chloro-acetic ether. Needles, v. e. sol. water and alcohol.  $(NEt_2.Cl.CH_2.CO_2Et).PtCl_4$ : orange crystals.— $(NEt_2.Cl.CH_2.CO_2Et).AuCl_4$ : [100°]; needles.

*Ethyl ether of the ethyl-iodide*  $NEt_2.I.CH_2.CO_2Et$ . From silver glyccol (3 mols.) and EtI (4 mols.) in the cold.

ETHYL- $\alpha$ -AMIDO-ACETOPHENONE  $C_9H_9(NHEt).CO.CH_3$ . Oil. Obtained by heating  $\alpha$ -amido-acetophenone with ethyl bromide  $B'_2H_2Cl_2PtCl_4$ : golden-yellow plates (Baeyer, B. 17, 970).

ETHYL-AMIDO-AZO-COMPOUNDS v. AZO-COMPOUNDS.

ETHYL-AMIDO-BENZENE a. ETHYL-ANILINE.

ETHYL-AMIDO-BENZENE SULPHONIC ACID  $NHEt.C_6H_4.SO_3H$ . From ethyl-aniline

and  $\text{H}_2\text{SO}_4$  at  $200^\circ$  (Smyth, *B.* 7, 1241).— $\text{BaA}'_2$  2aq.

Di-ethyl-amido-benzene sulphonic acid  $\text{NEt}_2\text{C}_6\text{H}_4\text{SO}_3\text{H}$ . From di-ethyl-aniline and  $\text{H}_2\text{SO}_4$  (8).— $\text{BaA}'_2$  2aq.

**ETHYL-*o*-AMIDO-BENZOIC ACID.** *Amide*  $[2:1]\text{C}_6\text{H}_4(\text{NHEt})\text{CONH}_2$ . [129°]. From *o*-amido-benzamide and EtI in alcohol at  $100^\circ$  (Finger, *J. pr.* [2] 37, 441). Crystalline mass, sol. hot water. Gives rise to a nitrosamine  $\text{C}_6\text{H}_4(\text{N}(\text{NO})\text{Et})\text{CONH}_2$  [110°].

**Ethyl-*m*-amido-benzoic acid**  $\text{C}_6\text{H}_4\text{NO}_2$  *i.e.*  $[3:1]\text{C}_6\text{H}_4(\text{NHEt})\text{CO}_2\text{H}$ . [112°]. When potassium *m*-amido-benzoate is boiled with alcoholic EtI a mixture of ethyl- and di-ethyl-amido-benzoic acids is produced; these may be separated by crystallisation of their hydrochloride from hot dilute HCl (Griess, *B.* 5, 1038). Small prisms, sl. sol. hot water, v. e. sol. alcohol and ether. Its solution is tasteless, but acid in reaction. It forms salts with mineral acids but not with HOAc. It gives a nitrosamine  $\text{C}_6\text{H}_4(\text{N}(\text{NO})\text{Et})\text{CO}_2\text{H}$  which crystallises (from water) in yellowish-white long narrow plates, and forms a crystalline silver salt  $\text{C}_6\text{H}_4\text{AgN}_2\text{O}_4$ .

**Salts.**— $\text{HA}'\text{HCl}$ : small four- or six-sided plates; also (from dilute HCl) in needles; m. sol. cold, v. sol. hot, water; v. sl. sol. cold HCl aq.— $\text{BaA}'_2$  2aq: indistinct plates (from alcohol).

**Di-ethyl-*m*-amido-benzoic acid**  $\text{C}_{10}\text{H}_{11}\text{NO}_2$  *i.e.*  $[3:1]\text{C}_6\text{H}_4(\text{NEt}_2)\text{CO}_2\text{H}$ . [90°]. Formed as above (G.). White prisms (containing 2aq); may be distilled.— $\text{HA}'\text{HCl}$  aq: shining four-sided plates, v. sol. cold water and HCl aq.

**Di-ethyl-*p*-amido-benzoic acid**  $[4:1]\text{C}_6\text{H}_4(\text{NEt}_2)\text{CO}_2\text{H}$ . [188°]. From *p*-amido-benzoic acid, KOH, and alcoholic EtI. Also by saponifying its chloride which is obtained by treating di-ethyl-aniline with  $\text{COCl}_2$  (Michler a. Gradmann, *B.* 9, 1912). Small plates (from alcohol).— $\text{H}_2\text{A}'\text{H}_2\text{PtCl}_6$ .— $\text{AgA}'$ .

**Ethyl ether EtA'**. (315°). Formed, together with the acid, by treating potassium *p*-amido-benzoate with EtI in the cold (Michael a. Wing, *Am.* 7, 198). Oil.

**Di-ethyl-di-amido-benzoic acid**  $\text{C}_{10}\text{H}_{10}\text{N}_2\text{O}_2$  *i.e.*  $\text{C}_6\text{H}_2(\text{NEt}_2)(\text{NH}_2)\text{CO}_2\text{H}$ . From di-ethyl-*m*-amido-benzoic acid by nitration and reduction. Also from benzene-azo-di-ethyl-amido-benzoic acid by reduction (Griess, *B.* 10, 527). Grey needles or prisms (from alcohol).

***p*-DI-ETHYL-AMIDO-BENZOIC ALDEHYDE**  $\text{C}_6\text{H}_4(\text{NEt}_2)\text{CHO}$  [1:4]. [41°]. Needles. Sol. water, alcohol, ether, &c. Formed by the action of alkalis upon di-ethyl-amido-phenyl-tri-chloro-ethyl-alcohol  $\text{CCl}_3\text{CH}(\text{OH})\text{C}_6\text{H}_4\text{NEt}_2$ , the condensation product of chloral and diethylaniline (Boessneck, *B.* 19, 369).

**DI-ETHYL-AMIDO-BENZOPHENONE**  $\text{C}_6\text{H}_4\text{CO}_2\text{C}_6\text{H}_4\text{NEt}_2$ . [78°]. *Benzoyl-phenyl-di-ethyl-amine*. From tetra-ethyl-di-amido-tri-phenyl-carbinol and conc. HCl at  $180^\circ$  (Doebner, *A.* 217, 265). Trimetric crystals (from alcohol). Insol. water, sl. sol. cold alcohol, v. sol. hot alcohol. Very feebly basic, dissolving in conc. HCl, but reppd. by water.

**Tetra-ethyl-di-amido-benzophenone**  $\text{CO}(\text{C}_6\text{H}_4\text{NEt}_2)_2$ . [96°]. Formed, together with  $\text{C}_6\text{H}_4(\text{NEt}_2)(\text{CO}_2\text{C}_6\text{H}_4\text{NEt}_2)$ , [170°], by saturating di-ethyl-aniline with  $\text{COCl}_2$ , adding half the

original volume of di-ethyl-aniline and heating at  $120^\circ$  (Michler a. Gradmann, *B.* 9, 1912). Small laminæ (from alcohol).— $\text{B}'\text{H}_2\text{PtCl}_6$ .

**ETHYL-*α*-AMIDO-*n*-BUTYRIC ACID**  $\text{C}_6\text{H}_5\text{NO}_2$  *i.e.*  $\text{CH}_3\text{CH}_2\text{CH}(\text{NHEt})\text{CO}_2\text{H}$ . From *α*-bromo-butyric acid and ethylamine (Duvillier, *A. Ch.* [5] 20, 196; *C. R.* 88, 425; 97, 1486). Crystalline leaflets, subliming above  $110^\circ$  without fusion; v. sol. water, sl. sol. cold alcohol. Mixed with cyanamide in aqueous solution, with addition of a few drops of ammonia, there is formed in a month crystals of di-cyan-di-amide, while from the mother-liquor ethyl-*α*-amido-butyro-

cyamide  $\text{CH}_3\text{CH}_2\text{CH} \begin{matrix} \nearrow \text{NET.C.NH} \\ \searrow \text{CO.NH} \end{matrix}$  may be ob-

tained in tabular crystals, v. sol. water and alcohol.— $\text{HA}'\text{HCl}$ : opaque, ill-defined, deliquescent crystals.— $\text{H}_2\text{A}'\text{H}_2\text{PtCl}_6$ : orange-red crystals, v. sol. water and alcohol, sl. sol. ether.— $\text{CuA}'_2$  2aq: blue leaflets.

**Di-ethyl-*α*-amido-butyric acid**  $\text{C}_6\text{H}_5\text{NO}_2$  *i.e.*  $\text{CH}_3\text{CH}_2\text{CH}(\text{NEt}_2)\text{CO}_2\text{H}$ . [185°]. From *α*-bromo-butyric acid (1 mol.) and  $\text{NEt}_2\text{H}$  (1 mol.) (Duvillier, *C. R.* 100, 860). Deliquescent crystalline solid, v. sol. water and alcohol, sl. sol. ether. May be distilled with partial decomposition. The cupric salt forms violet-red crystals and dissolves in water and alcohol, forming a violet solution.

**ETHYL-AMIDO-CHLORO-*v.* CHLORO-ETHYL-AMIDO-.**

**ETHYL-*α*-AMIDO-CINNAMIC ACID**

$\text{C}_6\text{H}_5\text{NO}_2$  *i.e.*  $\text{C}_6\text{H}_4(\text{NEt}_2)\text{CH}:\text{CH}:\text{CO}_2\text{H}$ . [125°]. From *o*-amido-cinnamic acid, KOH, EtI, and alcohol by boiling (Fischer a. Kuzel, *A.* 221, 267; *B.* 16, 659; cf. Friedländer a. Weinberg, *B.* 15, 1423). Groups of small crystals (from light petroleum). Sl. sol. water, sol. alcohol, ether, and  $\text{CS}_2$ , forming a yellow solution with green fluorescence.

**Nitrosamine**  $\text{C}_6\text{H}_4(\text{NEt}_2\text{NO})\text{CH}:\text{CH}:\text{CO}_2\text{H}$ . [150°]. Formed by the action of  $\text{H}_2\text{SO}_4$  and  $\text{KNO}_2$  on the above. Yellowish plates from dilute (25 p.c.) alcohol. Insol. light petroleum, v. sol. ether and chloroform. Insol. acids in the cold. Reduced by zinc and acetic acid to  $\text{NH}_2\text{NEt}_2\text{C}_6\text{H}_4\text{CH}:\text{CH}:\text{CO}_2\text{H}$ , which is oxidised by the air to ethyl-quinazole carboxylic acid (Fischer a. Tafel, *A.* 227, 332).

**Di-ethyl-*α*-amido-cinnamic acid**  $\text{C}_6\text{H}_5\text{NO}_2$  *i.e.*  $\text{C}_6\text{H}_4(\text{NEt}_2)\text{CH}:\text{CH}:\text{CO}_2\text{H}$ . [124°]. From amido-cinnamic acid, KOH, alcohol, and EtI (Fischer a. Kuzel, *A.* 221, 269). Pale lemon-coloured plates (from alcohol). Its solutions in alcohol, ether, or  $\text{CS}_2$  exhibit bluish-green fluorescence.

**ETHYL-AMIDO-CUMINIC ACID**  $\text{C}_{12}\text{H}_{13}\text{NO}_2$  *i.e.*  $\text{C}_6\text{H}_5\text{CH}_2(\text{NHEt})\text{O}_2$ . From amido-cuminic acid and EtI at  $105^\circ$  (Lippmann a. Lange, *B.* 13, 1662).— $\text{AgA}'$ .

**ETHYL-AMIDO-ETHANE SULPHONIC ACID**  $\text{NHEt}.\text{CH}_2\text{CH}_2\text{SO}_3\text{H}$ . *Ethyl-taurine*. [147°]. From ethylamine and *β*-chloro-ethane sulphonic acid at  $160^\circ$  (James, *J. pr.* [2] 81, 414). Prisms (from water).

**Di-ethyl-amido-ethane sulphonic acid**  $\text{NEt}_2.\text{CH}_2\text{CH}_2\text{SO}_3\text{H}$ . [151°]. From diethylamine and  $\text{ClCH}_2\text{CH}_2\text{SO}_3\text{H}$  (J.). Trimetric tables (from alcohol). V. e. sol. water.

**ETHYL-AMIDO-ETHYL ALCOHOL** v. **Oxy-ethyl-amine**.

**ETHYL- $\alpha$ -AMIDO-HEXOIC ACID**  $C_8H_{11}NO_2$ , i.e.  $CH_3(CH_2)_4CH(NH_2)CO_2H$ . S. 10-7 at 15°. From  $\alpha$ -bromo-hexoic acid and ethylamine (Duvillier, *C. R.* 90, 822; *A. Ch.* [5] 29, 172). Pearly plates (from alcohol). Sl. sol. cold, m. sol. hot, alcohol, insol. ether. Its aqueous solution has a neutral reaction and bitter taste; it gives with  $FeCl_3$  an intense red colouration, and on boiling a reddish-brown pp. Cyanamide forms the creatinin  $CH_3(CH_2)_4CH \begin{matrix} \diagup \\ \text{NET.C:NH} \\ \diagdown \\ \text{CO.NH} \end{matrix}$ , which

crystallises in long needles, m. sol. hot water, v. sol. alcohol (Duvillier, *C. R.* 96, 1583).

**Salts.**—The hydrochloride forms deliquescent laminae, v. sol. alcohol, insol. ether; the aurochloride is a golden crystalline mass. ( $HA'HCl$ ) $PtCl_4$ : orange prisms.— $CuA'$ . S. 1 in the cold.

**ETHYL-AMIDO-HYDROCARBOSTYRIL** v. **Oxy-ethyl-amido-quinoline dihydride**.**ETHYL- $\alpha$ -AMIDO-HYDROCINNAMIC ACID** v. **ETHYL- $\alpha$ -AMIDO-PHENYL-PROPIONIC ACID**.**TETRA-ETHYL-DI-AMIDO-METHANE** v. **Tetra-ethyl-methylene-diamine**.

**DI-ETHYL- ( $\alpha$ )-AMIDO-NAPHTHALENE SULPHONIC ACID**  $NET_2C_8H_6SO_3H$ . From di-ethyl-naphthylamine and  $H_2SO_4$  (Smith, *C. J.* 41, 184). Needles.— $BaA'$ .

**DI-ETHYL-AMIDO-NAPHTHOIC ACID**  $NET_2C_{10}H_7CO_2H$ . Di-ethyl-( $\alpha$ )-naphthylamine dissolved in benzene is converted by  $COCl_2$  into a mixture of two isomeric chlorides of the formula  $NET_2C_{10}H_7COCl$  [70°] and [225°] with the compound  $NET_2C_{10}H_7(CO.O.C_6H_5.NET_2)$  [130°] (Smith, *C. J.* 41, 185).

**ETHYL-AMIDO-NAPHTHOQUINONE**  $C_{12}H_9O_2(NH_2)$ . [140°]. From naphthoquinone and ethylamine (Plimpton, *C. J.* 37, 639). Red needles; may be sublimed; v. sol. hot alcohol and benzene, v. sl. sol. ligroin.

**TETRA-ETHYL-DI-AMIDO-DI-NAPHTHYL**  $C_{26}H_{20}N_4$ , i.e.  $NET_2C_{10}H_7C_{10}H_7.NET_2$ . [190°]. (Much above 360°). Formed by heating di-ethyl-naphthylamine (20 g.) with  $H_2SO_4$  (20 g.) for eight hours at 190°-210°. Crystallises in colourless tufts (from alcohol). Sol.  $HCl$  (giving a red solution), strong  $HNO_3$  (intense red colour). V. sol. hot alcohol, m. sol. cold alcohol, sl. sol. ether, v. sol. benzene and  $CHCl_3$ .

**Salts.**— $B''2(HCl)$  (B. E. Smith, *C. J.* 41, 182).  **$\alpha$ -ETHYL-AMIDO-PHENOL**

$C_8H_9(NH_2)OH$  [1:2]. [168°]. Obtained by heating its ether with fuming  $HCl$  for five hours at 150° (Förster, *J. pr.* [2] 21, 350). The product is mixed with  $NaOH$ , extracted with ether, the extract dried over  $CaCl_2$ , and the ether is then boiled off. Trimetric plates. V. sol. alcohol, less sol. benzene,  $CS_2$ , chloroform and ether. Cannot be distilled undecomposed.

**Salts.**—Unstable, decomposing partially when their solutions are evaporated, a resin being formed.— $B'HCl$ .—( $B'HCl$ ) $PtCl_4$ .— $B'HBr$ .

**Nitrosamine**  $C_8H_9(OH)N_2(NO)$ . [121°]. Formed by passing nitrous acid gas into a solution of the hydrochloride at 0°. Grey plates. Neither acid nor basic.

**Ethyl ether**  $C_8H_9(NH_2)OEt$  [1:2]. (235°). S.G. 1.021. Prepared by heating 100 grms.

of  $\alpha$ -amido-phenetol with 84 grms. of  $EtBr$  for five hours at 60°. The product is mixed with soda and extracted with ether. The base is dried over  $CaCl_2$  and distilled (Förster, *J. pr.* [2] 21, 346). Oil. Gradually turns brown. Miscible with ether,  $CS_2$ , chloroform, benzene, and methyl alcohol. Sol. ethyl alcohol. With bleaching powder its solution gives a brown colour.  $H_2SO_4$  and  $K_2Cr_2O_7$  give a brown colour.  $H_2SO_4$  dissolves it, forming a reddish-violet solution, the colour being destroyed by water. Nitrous acid gas forms a nitro-nitrosamine  $C_8H_9(NO_2)(OEt)N_2(NO)$ .

**Salts.**— $B'HBr$ : trimetric plates.— $B'HI$ : trimetric plates.— $B'HCl$ : trimetric plates.—( $B'HCl$ ) $PtCl_4$ . V. sol. water. Thrown down by fuming  $HCl$ .— $B'HT_2O$ . Prisms.

**Di-ethyl- $\alpha$ -amido-phenol**  $C_8H_9(NEt_2)(OH)$  [1:2]. (220°). Obtained from its ethyl ether by conc.  $HCl$  (Förster, *J. pr.* [2] 21, 367).

**Properties.**—Oil. Turns green in air, but when heated to its boiling-point suddenly loses this colour. When moist it decomposes on distillation. It has a peppery taste, is volatile with steam, and is sol. ether, benzene, chloroform, and alcohol.

**Reactions.**—1. With  $FeCl_3$  a deep brownish-red colour.—2.  $H_2SO_4$  and  $K_2Cr_2O_7$  a similar colour.—3. Solution of bleaching powder gives a wine-red colour.—4. Bromine water gives a yellow pp., changing quickly to a brown resin.—5. Conc.  $H_2SO_4$  dissolves it, forming a violet solution.

**Salts.**—Crystallise very well. The base cannot expel  $NH_3$  from its salts. Solutions of its salts decompose somewhat on evaporating.  $B'IBr$ .— $B'HI$ .—( $B'HI$ ) $PtCl_4$ .

**Ethyl ether**  $C_8H_9(NEt_2)OEt$  [1:2]. (228°) The ethyl ether of  $\alpha$ -amido-phenol (2 pts.) and  $EtI$  (3 pts.) are heated together in alcoholic solution for twelve hours at 130°; after evaporation the residue is mixed with solution of soda, shaken with ether, and the extract dried over  $CaCl_2$  and distilled (Förster). Oil. Miscible with alcohol, ether, benzene,  $CHCl_3$ , and  $CS_2$ . Bleaching-powder solutions give a red colour.  $H_2SO_4$  and  $K_2Cr_2O_7$  a reddish-brown colour. Conc.  $H_2SO_4$  forms a violet solution.

**Salts.**—Glue-like masses.  $B'HBp$ . **DI-ETHYL-AMIDO-DIPHENYL**  $C_{18}H_{15}N$  i.e.  $C_6H_5C_6H_4.NET_2$ . [below 100°]. From  $p$ -amido-diphenyl and  $EtI$ , followed by  $Ag_2O$  (Hofmann, *Pr.* 12, 389). Long white needles; insol. water, m. sol. alcohol, v. sol. ether; may be distilled.— $B'HI$ .— $B'HBp$ .— $B'HI$ .

**Methylo-iodide**  $C_8H_9C_6H_4.NET_2.MeI$ . Forms crystalline  $(C_8H_9C_6H_4.NET_2.MeCl)_2.PtCl_4$ .

**Tetra-ethyl-di-amido-diphenyl**  $NET_2C_6H_4C_6H_4.NET_2$ . **Tetra-ethyl-benzidine**. [85°]. Formed by heating di-ethyl-aniline with  $H_2SO_4$  to about 200°, and by ethylation of benzidine (Michler & Pattinson, *B.* 14, 2166). White needles. Sol. alcohol and ether, insol. water. Gives a green colouration with  $FeCl_3$  or  $CrO_3$ .

**TETRA-ETHYL-DI-AMIDO-TRI-PHENYL-CARBINOL**  $C_{27}H_{21}N_4O$  i.e.  $C_6H_5C(OH)(C_6H_4.NET_2)_3$ . Base of 'Brilliant green.' From di-ethyl-aniline, benzotrichloride and  $ZnCl_2$  (Doebner, *A.* 217, 261). Also from di-ethyl-aniline and benzoic aldehyde and oxida-

dion of the product (Fischer, B. 14, 2521). Reddish amorphous solid; sl. sol. water, v. sol. alcohol. Its solution in alcohol and in dilute acids is green; in concentrated acids it forms a yellowish-brown solution. Heated with conc. HCl at 180° it forms di-ethyl-aniline and di-ethyl-amido-benzo-phenone:  $C_6H_5C(OH)(C_2H_5NEt_2)_2 = C_6H_5CO.C_2H_5NEt_2 + C_2H_5NEt_2$ .

**Salts.**—Dye a yellowish shade than malachite green.  $C_{20}H_{25}N_3H_2SO_4$ . Golden crystals. Its solution in alcohol or water is emerald green. —  $(C_{20}H_{25}N_3H_2Cl)_2.ZnCl_2.2aq.$  —  $B'H_2C_2O_4.aq.$ : golden prisms.

*Leuco-base*  $C_6H_5CH(C_2H_5NEt_2)_2$ . [62°].

**ETHYL-AMIDO-PHENYL-CHLORO-ETHYL ALCOHOL** v. CHLORO-ETHYL-AMIDO-PHENYL-ETHYL ALCOHOL.

**ETHYL-o-AMIDO-PHENYL-ETHANE**  $C_6H_4N$  i.e.  $C_6H_4C_2H_4NHET$ . From amido-phenyl-ethane and EtBr (Bernthsen, A. 184, 304). Laminae.—B'HBr: tables.— $B'H_2PtCl_6$ .

**Deca-ethyl-pent-amido-penta-phenyl-ethane**  $(Et.N.C_6H_4)_5C.CH(C_2H_5NEt_2)_2$ . [158°]. Obtained by heating 20 pts. of chloral hydrate, 50 pts. of diethylaniline and 10 pts. of  $ZnCl_2$  at 100° for five hours. On oxidation it gave a bluish-green dye-stuff (Boessneck, B. 19, 367).

**TETRA-ETHYL-DI-AMIDO-TRI-PHENYL METHANE**  $C_6H_5OH(C_2H_5NEt_2)_3$ . [62°]. From the carbinol, zinc-dust, and HCl (Doebner, A. 217, 203). From di-ethyl-aniline, benzoic aldehyde and  $ZnCl_2$ . Colourless glassy needles. V. sl. sol. water, v. sol. ether, alcohol, or benzene.  $B'H_2Cl_2PtCl_3.3aq.$

**Tetra-ethyl-tri-*ppo*-amido-tri-phenyl-methane**  $(C_6H_5.NEt_2)_3HC(C_2H_5NEt_2)_3$ . *Tetra-ethyl-para-leucaniline*. [118°]. Fine concentric needles. Formed by reduction of tetra-ethyl-*p*-di-amido-*p*-nitro-tri-phenyl-methane with zinc-dust and dilute HCl. On oxidation it gives a violet colouring-matter. The acetyl derivative on oxidation yields a green dye-stuff, which dissolves in benzene with a strong fluorescence (Kaeswurm, B. 19, 747).

**Tetra-ethyl-tri-*ppo*-amido-tri-phenyl-methane**  $C_6H_5(NH_2).CH(C_2H_5NEt_2)_3$ . *o-Amido-leuco-brilliant-green*. [136°]. White needles (containing  $C_6H_6$ ). Formed by reduction of the condensation product of diethylaniline and *o*-nitro-benzoic aldehyde, by means of zinc-dust and HCl (Fischer a. Schmidt, B. 17, 1894).

**Hexa-ethyl-tri-amido-tri-phenyl-methane**  $CH(C_2H_5NEt_2)_3$ . Triclinic crystals;  $a:b:c = 1.843:1.2$ ;  $\alpha = 86^\circ 9'$ ;  $\beta = 102^\circ 38'$ ;  $\gamma = 91^\circ 32'$  (Haushofer, Z. K. 9, 533).

**TETRA-ETHYL-DI-AMIDO-DI-PHENYL-NITRO-PHENYL-METHANE** v. NITRO-TETRA-ETHYL-DI-AMIDO-TRI-PHENYL-METHANE.

**TETRA-ETHYL-DI-AMIDO-DI-PHENYL OXIDE**  $O(C_2H_5NEt_2)_4$ . [89°]. From  $S(C_2H_5NEt_2)_2$  and silver nitrate (Holzmann, B. 21, 2061). Needles, insol. water, sl. sol. cold alcohol and ether.— $B'H_2PtCl_6$ . [c. 100°]. Yellow flocculent pp., sl. sol. warm alcohol.—Piorate  $B'2O.C_2H_5(NO_2)_2OH_2$ . [174°]. Yellow crystalline pp., sl. sol. hot alcohol.

**Tetra-ethyl-di-amido-di-phenyl peroxide**  $O_2(C_2H_5NEt_2)_4$ . [67°]. From the corresponding sulphide by treatment with ammoniacal  $AgNO_3$  (Holzmann, B. 20, 1636). Needles or prisms. Decomposed by moist air.

**HEXA-ETHYL-TRI-AMIDO-DI-PHENYL-PHENYLENE DIKETONE**  $C_{20}H_{25}N_3O_2$  i.e.  $C_6H_4(NEt_2)(CO.C_2H_5NEt_2)_2$ . [c. 176°]. From tetra-ethyl-di-amido-benzophenone, di-ethyl-aniline, and  $COCl_2$  at 120° (Michler a. Gradmann, B. 9, 1912). Triclinic crystals (from alcohol).

**TETRA-ETHYL-DI-AMIDO-DI-PHENYL-PROPANE**  $OMe_2(C_2H_5NEt_2)_4$ . [76°]. Prepared by heating acetone (10 pts.) with diethylaniline (50 pts.) and zinc chloride (30 pts.) in sealed tubes for 12 hours to 170° (Doebner a. Petschow, A. 242, 334). Long needles. Insol. water, sl. sol. cold, v. sol. hot, alcohol. Sol. ether,  $CS_2$ , petroleum-ether, and benzene.

**Salts.**— $B'H_2I_2$ , reddish yellow pp.; v. sol. hot water and alcohol.

**o-ETHYL-AMIDO- $\beta$ -PHENYL-PROPIONIC ACID**  $C_6H_4(NHEt)CH_2CH_2CO_2H$ . *Ethyl-amido-hydrocinnamic acid*. From *o*-ethyl-amido-cinnamic acid and sodium amalgam in alkaline solution (Friedländer a. Weinberg, B. 15, 2104; Fischer a. Kuzel, B. 16, 1449; A. 221, 271). Dilute  $H_2SO_4$  throws down the acid as a white flocculent pp., excess of  $H_2SO_4$  dissolves it, and on warming its anhydride oxy-ethyl-quinoline dihydride (ethyl-hydrocarbostyryl) separates as an oil.

**Nitrosamine**  $C_6H_4(NEtNO)CH_2CH_2CO_2H$ . [78°]. Formed by adding  $NaNO_2$  to a solution of the acid in  $H_2SO_4$ . Groups of colourless oblong plates (from dilute acetic acid). Decomposes at 150°. Sol. alcohol, ether, benzene, and alkalis. Gives Liebermann's reaction. On reduction with zinc-dust and acetic acid it gives  $C_6H_4(NEt.NEt_2)CH_2CH_2CO_2H$ , which on evaporating leaves its lactam, ethyl-quinazole dihydride.

**TETRA-ETHYL-DI-AMIDO-DI-PHENYL-DI-SULPHIDE**  $S_2(C_2H_5NEt_2)_4$ . [80°]. From di-ethyl-aniline and  $S_2Cl_2$  in ligroin (Holzmann, B. 20, 1636; 21, 2056). Golden prisms; sl. sol. ether, m. sol. alcohol and benzene. Decomposed by water. Forms a crystalline picrate [175°] and platino-chloride.

**TRI-ETHYL-TRI-AMIDO-DI-PHENYL-TOLYL CARBINOL**  $C_{20}H_{25}N_3O$  i.e.  $C_6H_4Me(NHEt)C(OH)(C_2H_5NEt)_3$ . *Tri-(?)ethyl-rosaniline*. From rosaniline (1 pt.), EtI (1 pt.), KOH (1 pt.), and alcohol (Hofmann, A. 132, 163).— $C_{20}H_{25}N_3IHI$ : lustrous green crystals which form a violet solution in water.

**ETHYL- $\alpha$ -AMIDO-PROPIONIC ACID**  $C_6H_{11}NO$  i.e.  $CH_3CH(NHEt)CO_2H$ . S. 50 at 25°. S. (alcohol) 2 at 25°. Formed by boiling  $\alpha$ -bromo-propionic acid with ethylamine (Duvillier, A. Ch. [6] 7, 427; C. R. 99, 1120; 100, 916). Monoclinic crystals (containing  $\frac{1}{2}$  aq) or nacreous plates (from alcohol); sol. water and alcohol. Its hydrochloride forms deliquescent needles. It forms a crystalline platino-chloride and aurochloride.— $CuA_2.2aq$ : blue prisms, sol. water and alcohol. When its saturated solution is mixed with a solution of cyanamide there is deposited in three months a crystalline homologue of creatinin

**ETHYL-AMIDO-ISOPROPYL ALCOHOL** *c.*  
**ETHYL-OXY-ISOPROPYL-AMINE.**

**DI-ETHYL-AMIDO-PROPYLENE-GLYCOL** *c.*  
**DI-ETHYL-DI-OXY-PROPYL-AMINE.**

**ETHYL-AMIDO-TOLUENE** *v.* **AMIDO-TOLYL-ETHANE** and **ETHYL-TOLUIDINE.**

**Ethyl-tri-amido-toluene**  $C_8H_7N_3$ , *i.e.*  $C_6H_4Me(NHEt)(NH_2)$ , [ $\lambda$ :43.5]. Obtained by reducing di-nitro-*p*-tolyl-ethyl-nitramine with tin and HCl (Van Romburgh, *R. T. C.* 3, 412).

**$\alpha$ -ETHYL-AMIDO-ISOVALERIC ACID**  
 $C_8H_{11}NO$ , *i.e.*  $(CH_3)_2CH.CH(NHEt).CO_2H$ . From bromo-isovaleric acid and ethylamine (Duvillier, *A. Ch.* [5] 21, 439; *C. R.* 88, 425). Groups of slender white needles; sol. water and alcohol, insol. ether. Neutral to litmus. Sublimes above  $110^\circ$ .— $HA \cdot HCl$ : confusedly crystalline; *v.* sol. water and alcohol, insol. ether.— $CuA \cdot 2aq$ : crystalline violet mass forming an intense blue solution.—The platinochloride and aurochloride are exceedingly deliquescent.

**ETHYLAMINE**  $C_2H_5N$  *i.e.*  $NH_2Et$ . Mol. w. 45. ( $19^\circ$ ). S.G. = 0.6964. V.D. 1.5767. H.F.p. 17.510. H.F.v. 15.770 (*Th.*).

**Compressibility:** Isambert, *C. R.* 105, 1173.  
**Formation.**—1. By boiling cyanic or cyanuric ether with potash (Wurtz, *C. R.* 28, 223, 823; *A. Ch.* [3] 30, 443).—2. Together with  $NH_3$  by boiling ethyl-urea with potash (W.).—3. By the action of ammonia on the ethers of inorganic acids, *e.g.*:  $EtBr$  and  $EtI$  (Hofmann, *C. J.* 13, 331),  $EtCl$  (Groves, *C. J.* 13, 331),  $Et_2PO$  (De Clermont, *A. Ch.* [3] 44, 335),  $Et_2SO$  (Strecker, *A.* 75, 46),  $EtNO_2$  (Juncadella, *C. R.* 48, 832),  $KEtSO_4$  (Erlenmeyer a. Carl, *J.* 1875, 617), and  $Et_2SO$  (Carius, *A.* 110, 203).—4. By heating chloride, bromide, or iodide of ammonium with alcohol or ether in sealed tubes (Berthelot, *A. Ch.* [3] 38, 63).—5. Formed, together with di- and tri-ethylamine, by heating absolute alcohol with ammoniacal  $ZnCl_2$  at  $260^\circ$ ; the yield of mixed bases amounts to about 46 p.c. of the alcohol used (Merz a. Gasiorowski, *B.* 17, 637).—6. From propionitrile, zinc, and dilute  $H_2SO_4$  (Mendius, *A.* 121, 142).—7. By the dry distillation of alanine (Limpricht a. Schwanert, *A.* 101, 297). Occurs also among the products of the dry distillation of beet-root molasses (Duvillier a. Buisine, *A. Ch.* [5] 23, 317).—8. Occurs among the products of the putrefaction of yeast and flour (Hesse, *J. pr.* 71, 471; Sullivan, *J.* 1858, 231).—9. With di- and tri-ethylamine by heating white precipitate  $NH_4HgCl$  with  $EtI$  (Sonnenschein, *A.* 101, 20).—10. By heating acetamide with alcoholic sodium-ethylate at  $170^\circ$ – $200^\circ$  (Seifert, *B.* 18, 1857).—11. By the action of alkalis on propionic bromo-amide, or of bromine and KOH on propionamide; yield 80 p.c. of theoretical (Hofmann, *B.* 15, 753).—12. By reduction of a cold solution of aldehyde-phenyl-hydrazide in 5 pts. of alcohol by means of sodium-amalgam (2 p.c.) and acetic acid; yield 45 p.c. of the theoretical.  
 $B \cdot H_2Cl \cdot PtCl_4$ ; hexagonal prisms (Tafel, *R.* 19, 1926).

**Preparation.**—1. Cyanic ether is boiled with aqueous KOH, the escaping gas is absorbed by  $HClAq$ , and the ethylamine hydrochloride dried, mixed with quick-lime, and distilled (Wurtz). The potassium cyanate from which the cyanic ether is prepared (by distillation with  $KEtSO_4$ ) is

usually sufficiently impure to give off  $NH_3$ , which then produces all three ethylamines, so that the product is seldom quite pure.—2. Ethyl nitrate is heated with alcoholic ammonia.  $NH_4Cl$  is hardly soluble in alcohol, and the ethylamines are separated by crystallisation of their picrates (Carey Lea, *C. N.* 5, 118).—3. A mixture of propionamide (1 mol.) and bromine (1 mol.) is treated in the cold with a 5 p.c. solution of KOH, and the solution run slowly into a 30 p.c. solution of (8 mols. of) KOH at  $60^\circ$ – $70^\circ$  as described under methylamine; the yield is 80–90 p.c. (Hofmann, *B.* 15, 767).—4.  $EtBr$  is heated with conc.  $NH_4Aq$  in sealed tubes at  $100^\circ$  (Hofmann, *C. J.* 3, 300).—5.  $EtI$  is heated with aqueous  $NH_3$  at  $100^\circ$ . The product is distilled with KOH. The mixture of the three ethylamines is dried over KOH and mixed with oxalic ether. Ethylamine forms diethyl-oxamide  $NHEt.CO.CO.NHEt$ , di-ethylamine forms diethyl-oxamic ether  $NEt_2.CO.CO.CO_2Et$ , whilst the tri-ethylamine has no action, and is removed by distillation. The liquid di-ethyl-oxamic ether is then separated by filtration from the crystalline di-ethyl-oxamide. On distilling the di-ethyl-oxamide with potash ethylamine passes over.  $EtCl$  obtained as a by-product in the manufacture of chloral may be used instead of  $EtI$  in the above preparation (Hofmann, *B.* 3, 109, 776). When  $EtCl$  is heated in equimolecular proportions with conc.  $NH_4Aq$  at  $90^\circ$  a floating layer of tri-ethylamine containing free  $NH_3$  is formed, while ethylamine and diethylamine remain dissolved as salts, and constitute the chief product. The same mixture of  $EtCl$  and  $NH_4Aq$  when heated at  $150^\circ$  forms  $NH_4Cl$ , ethylamine hydrochloride, and  $NEt_2Cl$  as chief products, only traces of  $NHEt$ , and of  $NEt$ , (free) being formed (Malbot, *A. Ch.* [6] 13, 477; *C. R.* 105, 755).—6. A good modification of the preceding method, proposed by Groves (*C. J.* 13, 331), consists in heating ethyl chloride (1 mol.) with a solution of ammonia (1 mol.) in alcohol. After removing the insoluble ammonium chloride the alcohol is distilled off, and the hydrochlorides are decomposed by soda. The bases are received in water, sulphuric acid added, and the solution of the sulphates evaporated to a syrup. This is poured into absolute alcohol, in which ammonium sulphate is insoluble (*cf.* Wanklyn a. Chapman, *Pr.* 15, 218). The sulphates are again decomposed, and the bases received in water, and to the solution ethyl oxalate is added, in a quantity calculated on the supposition that the alkalinity is due to mono-ethylamine. The separated diethyl-oxamide is filtered off and the syrupy mother liquor is boiled for 12 hours with 10 times its volume of water, so as to form acid diethylamine oxalate and di-ethyl-oxamic acid. On concentration the former salt separates out in long needles, and on decomposition yields pure diethylamine. The molten liquor is decomposed with soda, the separated bases received in alcohol and again treated with ethyl oxalate, and the mixture distilled to remove the triethylamine and alcohol, and to the residue milk of lime is added to precipitate calcium mono- and di-ethyl-oxamate, which on decomposition yields diethylamine (Duvillier a. Buisine, *A. Ch.* [5] 23, 340; *C. R.* 88, 31).

**Properties.**—Colourless inflammable liquid;

does not solidify at  $-140^{\circ}$ . Possesses a pungent ammoniacal odour, a strong alkaline reaction, and burning taste, inflaming the tongue. It forms dense white fumes with HCl. It mixes with water, considerable rise of temperature taking place, but it is completely expelled again by boiling. Solid KOH separates it from its aqueous solution. It expels  $\text{NH}_3$  from ammonium salts. An aqueous solution of ethylamine resembles one of  $\text{NH}_3$  in behaviour towards many metallic salts; it differs in dissolving the ppd. oxides of aluminium, gold, and ruthenium, and in not dissolving the pps. which it gives with salts of Cd, Ni, and Co. It dissolves ppd. cupric hydroxide less readily than  $\text{NH}_3$  does. With  $\text{SnCl}_4$  it gives a pp. very soluble in excess. Phosphomolybdic acid gives a yellow pp. more soluble than the corresponding pp. obtained with ammonia. An alcoholic solution of chloro-tri-nitro-benzene (picryl chloride) gives the characteristic ethyl-picramide  $\text{C}_6\text{H}_4(\text{NO}_2)_3(\text{NHEt})$  with even small quantities of ethylamine (Van Romburgh, *R. T. C.* 2, 107). A concentrated aqueous solution of ethylamine that has been dehydrated as far as possible by KOH yields on distillation dry ethylamine gas, followed very soon by a liquid boiling below  $75^{\circ}$ , which is probably a hydrate of ethylamine (Wallach, *B.* 7, 326). From an examination of the compressibility of a solution of ethylamine in water, Isambert also concludes that chemical combination does take place between the water and the base (Isambert, *C. R.* 105, 1173).

**Reactions.**—1. On passing through a red-hot tube there is formed  $\text{NH}_3$ , hydrogen,  $\text{HCy}$ ,  $\text{CH}_4$ ,  $\text{C}_2\text{H}_6$ ,  $\text{C}_2\text{H}_4$ ,  $\text{C}_2\text{H}_2$ , and carbon (Muller, *Bl.* [2] 45, 438).—2. Nitrous acid produces nitrogen and alcohol (or nitrous ether).—3. Chromic acid mixture oxidises it to aldehyde, acetic acid, water, and nitrogen (Wanklyn a. Chapman, *C. J.* 20, 328).—4. Cyanic acid forms ethyl-urea.—5. Cyanic ether gives di-ethyl-urea.—6. *o*-Oxy-benzoic aldehyde forms syrupy  $\text{C}_6\text{H}_4\text{NO}$  ( $237^{\circ}$ ), sol. water (Dennstedt a. Zimmermann, *B.* 21, 1553).—7. Dry ethylamine hydrochloride is converted by  $\text{COCl}_2$  into  $\text{NHEt.COCl}$  at  $260^{\circ}$  (Gattermann a. Schmidt, *B.* 20, 118).—8. Allyl thiocarbimide (oil of mustard) gives ethyl-allyl-thio-urea (Hinterberger, *A.* 83, 346).—9. Gaseous cyanogen chloride forms ethyl-cyanamide, which is converted by boiling water into the isomeric iso-tri-ethyl-melamine (Hofmann, *B.* 2, 602; Cloez a. Cannizzaro, *A.* 78, 228).—10. Bleaching-powder gives ethyl-di-chloro-amine (Thorniak, *B.* 9, 143).—11. Di-chloro-naphthoquinone forms  $\text{NHEt.C}_6\text{H}_4\text{Cl}_2$  [ $110^{\circ}$ ].—12. Benzoic aldehyde in aqueous or alcoholic solution forms benzylidene-ethyl-amine  $\text{PhCH:NEt}$  ( $195^{\circ}$ ), an oil which is reduced by sodium-amalgam to benzyl-ethyl-amine  $\text{PhCH}_2\text{NHEt}$  (Zaunschirm, *A.* 245, 279).—13.  $\text{SO}_2$  forms ethyl sulphamic acid  $\text{NHEt.SO}_2\text{H}$ .

**Salts.**—The sulphate, chloride, tartrate, and other salts differ from the corresponding ammonium salts in being very much more soluble in alcohol.— $\text{B'EtCl}$  [ $76^{\circ}$ – $80^{\circ}$ ]. Mol. w. 81.  $R_{\infty}$   $85^{\circ}$ – $11^{\circ}$  in an 11 p.c. aqueous solution (Kanonnikoff). Large deliquescent laminae (from alcohol) or striated prisms (from water). On distillation it gives ethyl-amine, di-ethyl-amine,  $\text{EtCl}$ ,  $\text{C}_2\text{H}_6$ , and  $\text{NH}_3$  (Filleti a. Piccini, *B.* 12, 1508).— $\text{B'}_2\text{H}_4\text{PtCl}_4$ : orange hexagonal

rhombohedra. S.G.  $\frac{191}{4}$  2.253 (Clarke, *Am.* 2, 175). Not decomposed by boiling water (De Coninck, *Bl.* [2] 45, 131).— $\text{B'HAuCl}_4$ : very slender golden monoclinic prisms, sol. water, alcohol, and ether (Wurtz).— $\text{B'}_2\text{H}_4\text{HgCl}_4$ : small white scales (from alcohol).— $\text{B'HHgCl}_4$ : deliquescent trimetric crystals (Köhler, *B.* 12, 2211, 2324; Topsoë, *Z. K.* 8, 246).— $\text{B'HHgCl}_4$ : hexagonal rhombohedra.— $\text{B'HCiHgCy}_2$ : large laminae, permanent in the air, decomposed at  $100^{\circ}$ ; sol. water, sl. sol. cold alcohol (Kohl a. Swoboda, *A.* 83, 342).— $\text{B'}_2\text{H}_4\text{PdCl}_4$ : feathery tufts of large black crystals; red by transmitted light (Reckenschuss, *A.* 83, 343; cf. Müller, *A.* 86, 866).— $\text{B'}_2\text{H}_4\text{CuCl}_4$ : trimetric crystals.— $\text{B'HBBr}$ : crystalline.— $\text{B'}_2\text{H}_4\text{SO}_4^*$ : deliquescent gummy mass, v. sol. alcohol.— $\text{B'HNO}_3^*$ : very deliquescent thin laminae.— $\text{MgB'HPFO}_3$ : bulky pp. obtained by adding sodium phosphate to a solution of magnesium sulphate mixed with ethylamine or any of its salts; becomes crystalline on standing.— $\text{B'}_2\text{H}_4\text{Mo}_2\text{O}_7$ : white scales, becoming brown on drying (Meyer, *J. pr.* 67, 151).— $\text{B'}_2\text{H}_4\text{SO}_4\text{Al}(\text{SO}_4)_2$ : 24aq: S. 15 at  $25^{\circ}$ ; regular octahedra (Stenner a. Kammer, *A.* 91, 172).— $\text{B'H}_2\text{CO}_3(?)$ : very unstable crystalline mass obtained from  $\text{B'Cl}$  and  $\text{Na}_2\text{CO}_3$ .— $\text{B'HOAc}^*$ : deliquescent crystalline mass.— $\text{B'HS}$ : crystals; vapour-tension 48 at  $13^{\circ}$  (Isambert, *C. R.* 96, 708).— $\text{B'HVO}$ , (Bailey, *C. J.* 45, 692).— $\text{B'}_2(\text{H}_2\text{O})_2(\text{V}_2\text{O}_5)_3$ : 3aq.— $\text{B'}_2\text{H}_4\text{O}(\text{V}_2\text{O}_5)_3$ : red prisms (Ditte, *C. R.* 104, 1844).— $\text{B'HCyS}$ : deliquescent; not converted into ethyl-thio-urea at  $150^{\circ}$  (De Clermont, *Bl.* [2] 27, 198).— $\text{B'H}_2\text{C}_2\text{O}_4$ : trimetric laminae (Loschmidt, *Sitz. W.* 51 [2] 7, 384; *J.* 1865, 376).— $\text{B'}_2\text{H}_4\text{C}_2\text{O}_4$ : monoclinic crystals.—Camphorate  $\text{B'}_2\text{C}_6\text{H}_4\text{O}_4$ : small needles (Wallach a. Kamensky, *A.* 214, 242).—Mucoate  $\text{B'}_2\text{C}_6\text{H}_4\text{O}_4$ : 8aq: oblique rhombic prisms (Bell, *B.* 10, 1861).—Pimelate  $\text{B'}_2\text{C}_6\text{H}_4\text{O}_4$  (Wallach a. Kamensky, *B.* 14, 170).—Benzene sulphonate  $\text{C}_6\text{H}_5\text{SO}_3\text{HB'}$  [ $92^{\circ}$ ] (Norton a. Westenhoff, *Am.* 10, 129).—*p*-Toluene sulphonate  $\text{B'HSO}_3\text{C}_6\text{H}_4\text{Me}$  [ $111^{\circ}$ ] (Norton a. Otten, *Am.* 10, 140).—Combinations with salts.— $\text{B'HgCl}_2$ : crystalline pp. got by mixing alcoholic solutions of ethylamine and  $\text{HgCl}_2$  (Köhler, *B.* 12, 2208, 2323).— $\text{B'}_2\text{HgCl}_2\text{Hg}_2\text{O}_2$ : pp. got by mixing the aqueous solutions. By boiling with excess of  $\text{HgCl}_2$  there is formed an insoluble yellow salt  $\text{NHEt.HgClHgO}$ , while crystalline  $\text{NHEt.HgCl}$  remains in solution.— $\text{B'}_2\text{PtCl}_2$ : fawn-coloured powder.— $\text{B'}_2\text{PtCl}_2$ : 2aq: colourless crystals, v. sol. water.— $\text{B'}_2\text{PtSO}_4$ .— $\text{B'}(\text{NH}_4)\text{PtCl}_2$  (Gordon, *B.* 3, 174).— $\text{B'}_2\text{C}_6\text{H}_4\text{PtCl}_2$  (Martius a. Griess, *A.* 120, 326).

**Formyl derivative**  $\text{NHEt.CHO}$ . ( $197^{\circ}$ ). S.G. 21.952. Mixes with water, alcohol, and ether.

**Acetyl derivative**  $\text{C}_6\text{H}_5\text{NO}$  i.e.  $\text{NHAcEt}$ . ( $202^{\circ}$ ) S.G.  $\frac{42}{4}$  942. Formed by the action of ethylamine on acetic ether; or of  $\text{HOAc}$  on cyano ether (Wurtz, *A. Ch.* [3] 30, 491; *C. R.* 87, 180). Colourless liquid. Formed also by dehydrating ethylamine acetate.  $\text{PbCl}_2$  converts it into  $\text{C}_6\text{H}_5\text{ClN}$ , whence solid KOH forms, on warming, di-ethyl-acetamidine  $\text{C}_6\text{H}_5\text{N}$  (Wallach a. Hoffmann, *B.* 8, 1567; *A.* 184, 108).

**Di-acetyl derivative**  $\text{C}_6\text{H}_5\text{NO}_2$  i.e.  $\text{NEtAc}$ . ( $185^{\circ}$ – $192^{\circ}$ ). S.G. 22.1009. From

cyanic ether and  $\text{Ac}_2\text{O}$  at  $190^\circ$  (Wurtz, *A. Ch.* [3] 42, 43). Liquid.

**Valeryl derivative**  $\text{CMe}_2\text{CO.NHEt}$ . [49°]. ( $204^\circ$ ). Crystals; v. sol. water, alcohol, and ether; has no smell. Pure  $\text{HNO}_3$  attacks it slowly, giving off  $\text{N}_2\text{O}$  (Franchimont a. Klobbie, *R. T. C.* 6, 241).

**Heptoyl derivative**  $\text{C}_7\text{H}_{15}\text{CO.NHEt}$ . [6°]. ( $268^\circ$ ). Formed by heating ethylamine heptanoate to  $230^\circ$  (F. a. K.). Pure  $\text{HNO}_3$  gives off  $\text{N}_2\text{O}$ .

**Benzoyl derivative**  $\text{C}_6\text{H}_5\text{CO.NHEt}$ : [67°]; ( $260^\circ$ ); glistening needles (from water) or plates (from dilute alcohol). From ethylamine and  $\text{BzCl}$  (Romburgh, *R. T. C.* 4, 390). Formed also by the action of ethyl-carbamiochloride  $\text{OC(NHEt)Cl}$  upon benzene in presence of  $\text{AlCl}_3$  (Gattermann a. Schmidt, *B.* 20, 120; *A.* 244, 50).

**o-Amido-benzoyl derivative**  $\text{C}_6\text{H}_4(\text{NH}_2)\text{CO.NHEt}$ . [105°]. From isatoic acid and ethylamine (Finger, *J. pr.* [2] 37, 437). White colloidal mass; sol. alcohol and hot ligroin.

$\text{HNO}_3$  converts it into  $\text{C}_6\text{H}_4\langle\text{CO}\rangle\text{NEt}$ . [70°].

**Ethyl-chloro-amine**  $\text{NHEtCl}$ . **Acetyl derivative**  $\text{NAcEtCl}$ . Formed by passing chlorine into  $\text{NAcEtH}$  at  $-18^\circ$  (Norton a. Toherniak, *C. R.* 86, 1409). Liquid, v. sol. water, alcohol, and ether; decomposed by heat. Boiling soda-solution decomposes it into chloroform, ethyl-di-chloro-amine, ethyl carbamine and  $\text{NH}_4\text{Et}$ .

**Ethyl-bromo-amine**. **Acetyl derivative**.  $\text{NAcEtBr}$ . From acetyl-ethylamine by warming with a solution of bromine in aqueous  $\text{KBr}$  (N. a. T.).

**Ethyl-di-chloro-amine**  $\text{NCl}_2\text{Et}$ . (89°). S.G.  $\frac{1}{4}$  1.240;  $\frac{15}{4}$  1.230. Obtained by chlorinating ethylamine at  $0^\circ$  (Wurtz, *A. Ch.* [3] 30, 474). Prepared also by distilling ethylamine hydrochloride (100 g.) with bleaching-powder (250 g.) made into a thick cream with water (Toherniak, *B.* 9, 146). Pungent yellow oil; not solid at  $-30^\circ$ . Insol. acids. Decomposes spontaneously in damp air into  $\text{NH}_4\text{Cl}$ , ethylamine hydrochloride, chloroform, acetyl chloride, and acetonitrile. Reduced to  $\text{NH}_4\text{Et}$  by  $\text{H}_2\text{S}$ . Alkalies give  $\text{HOAc}$  and  $\text{NH}_3$ . Converts aniline into di- and tri-chloro-aniline, being itself reduced to  $\text{NH}_4\text{Et}$  (Pierson a. Heumann, *B.* 16, 1047). Reacts with  $\text{ZnEt}_2$ , diluted with ether with formation of ethylamine and tri-ethylamine (Köhler, *B.* 12, 770, 1869).

**Ethyl-di-iodo-amine**  $\text{NI}_2\text{Et}$ . From ethylamine and iodine (Wurtz; Raschig, *A.* 230, 221). Dark red pp.

**Diethylamine**  $\text{C}_2\text{H}_5\text{N}$  i.e.  $\text{NHEt}_2$ . Mol. w. 73. (56°). S.G.  $\frac{1}{4}$  726;  $\frac{15}{4}$  716;  $\frac{20}{4}$  706;  $\frac{25}{4}$  674 (Oudemans, *R. T. C.* 1, 56). S. V. 109 (Schiff). H.F.p. 29,320 (Th.), 31,100 (M.). H.F.v. 26,420 (Th.). H.C. 724,400 (gaseous); 716,900 (liquid) (Müller, *Bl.* [2] 44, 609).

**Formation**.—1. By heating ethylamine with  $\text{EtBr}$  (Hofmann, *T.* 1850, 120; *C. J.* 3, 300).—2. By heating ammonia with  $\text{EtCl}$ ,  $\text{EtBr}$ , or  $\text{EtI}$  as described under ethylamine.—3. Together with ethylamine by heating ethyl nitrate with ammonia (Carey Lea, *J. pr.* 86, 176).—4. Together with mono- and tri-ethyl-amine by heating

absolute alcohol with ammoniacal  $\text{ZnCl}_2$  at  $260^\circ$  (Mers a. Gasiorowski, *B.* 17, 637).

**Preparation**.—1. By treating its nitrosamine with conc.  $\text{HClAq}$  (Geuther, *Jenaische Zeitschr.* 7, 118).—2. By acting on di-nitro-di-ethyl-aniline  $\text{C}_6\text{H}_3(\text{NO}_2)_2\text{NEt}_2$  with dilute  $\text{KOH}$ , the other product being  $\text{C}_6\text{H}_3(\text{NO}_2)_2\text{OK}$ . The yield is good (Van Romburgh, *R. T. C.* 2, 35).—3. v. ETHYLAMINE.

**Properties**.—Volatile inflammable liquid with strong alkaline reaction; v. sol. water. It differs from ethylamine in not redissolving the pp. which it forms with zinc salts, in not ppg. a solution of  $\text{PdCl}_2$ , and in the fact that the pp. which it forms with  $\text{HgCl}_2$  is not soluble in acetic acid, whereas the pps. formed by ethylamine and by  $\text{NH}_3$  are soluble in  $\text{HOAc}$ .

**Reactions**.—1. When passed through a red-hot tube it forms  $\text{HCy}$ ,  $\text{NH}_3$ , carbon,  $\text{CH}_4$ , hydrogen,  $\text{C}_2\text{H}_2$ , benzene, and nitrogen, but no ethylene (Müller, *Bl.* [2] 45, 438).—2. Iodine forms an oily substitution product.—3. Potassium nitrile converts its hydrochloride into di-ethyl-nitrosamine  $\text{NEt}_2\text{NO}$ . This is a neutral yellowish oil, (177°), S.G.  $\frac{17.5}{4}$  951, V.D. 3.36 (calc. 3.53) (Geuther a. Krentzhage, *A.* 127, 43). It is split up by alcoholic  $\text{KOH}$  at  $140^\circ$  into  $\text{NH}_3$  and ethylamine.—4. Cyanic ether forms tri-ethyl-urea (Hofmann, *C. R.* 54, 252).—5. Cyanogen chloride forms liquid di-ethyl-cyanamide (190°) (Cloeze a. Cannizzaro, *A.* 78, 228).—6.  $\text{SO}_2$  forms di-ethyl-sulphamic acid  $\text{NEt}_2\text{SO}_2\text{H}$ .

**Salts**.— $\text{B}^+\text{HCl}$  [217°], ( $320^\circ$ – $330^\circ$ ), non-deliquescent plates (Wallach, *B.* 14, 748). V. e. sol. water, m. sol. alcohol, v. sol. chloroform (Behrend, *A.* 222, 119).— $\text{B}^+\text{H}_2\text{PtCl}_4$ : orange monoclinic crystals (Topsoe, *Z. K.* 8, 246).— $\text{B}^+\text{HAuCl}_4$ : trimetric crystals.— $\text{B}^+\text{HHgCl}_4$ : trimetric crystals.— $\text{B}^+\text{HCl(HgCl}_2)_2$ : hexagonal rhombohedra.— $\text{B}^+\text{H}_2\text{Cl}_2(\text{HgCl}_2)_2$ : dimorphous.— $\text{B}^+\text{H}_2\text{PtBr}_2$ : monoclinic.— $\text{B}^+\text{H}_2\text{S}$ : crystalline; its vapour-pressure is 150 mm. at  $10^\circ$  (Isambert, *C. R.* 96, 708).— $\text{B}^+\text{HNO}_3$ . [100°]. Long needles or prisms (Franchimont, *R. T. C.* 2, 338).— $\text{B}^+\text{H}_2\text{C}_2\text{O}_4$ : long needles, m. sol. water (Duvillier a. Buisine, *A. Ch.* [5] 23, 342). Benzene sulphamate  $\text{B}^+\text{HSO}_3\text{C}_6\text{H}_5$ : [139°] (Norton, *Am.* 10, 129).— $p$ -Toluene sulphamate  $\text{B}^+\text{HSO}_3\text{C}_6\text{H}_4\text{Me}$ : [88°] (N.).

**Formyl derivative**  $\text{NEt}_2\text{CHO}$  (178°). S.G.  $\frac{12}{4}$  908. From di-ethyl-oxamic acid by heating (Wallach, *B.* 14, 745). Liquid, miscible with water.— $\text{B}^+\text{H}_2\text{PtCl}_4$ .— $\text{B}^+\text{H}_2\text{PtCl}_4\text{2aq}$ . With  $\text{PbCl}_2$  it forms a base  $\text{C}_2\text{H}_5\text{N}_2$  (Wallach, *A.* 237, 236).

**Acetyl derivative**  $\text{C}_2\text{H}_5\text{NO}$  i.e.  $\text{NEt}_2\text{Ac}$ . (186°). S.G.  $\frac{25}{4}$  925 (Wallach a. Kamensky, *A.* 214, 235).

**Tri-chloro-acetyl derivative**  $\text{CCl}_3\text{CO.NEt}_2$  [27°] (F. a. K.); [90°] (C.). From  $\text{NHEt}_2$  and  $\text{CCl}_3\text{COCl}$  (Franchimont a. Klobbie, *R. T. C.* 6, 236). From hexa-chloro-acetone and  $\text{NHEt}_2$  (Cloeze, *A. Ch.* [6] 9, 145).

**Valeryl derivative**  $\text{CMe}_2\text{CO.NEt}_2$ . (203°). S.G.  $\frac{12}{4}$  891 (F. a. K.).

**Heptoyl derivative**  $\text{C}_7\text{H}_{15}\text{CO.NEt}_2$ . [below  $-15^\circ$ ]. (258°). S.G.  $\frac{12}{4}$  881 (F. a. K.).

**Benzoyl derivative**  $\text{NEt}_2\text{Bz}$ . (282°). S.G.  $\frac{12}{4}$  1019; oil; sol. dilute  $\text{HCl}$  but reppd.

by water (Hallmann, *B.* 9, 846; Romburgh, *B. T. C.* 4, 887).

**Triethylamine**  $C_6H_{15}N$  i.s.  $NEt_3$ . Mol. w. 101 (cf. Dewar a. Scott, *Pr.* 85, 347). (90°). S.G. 0.7277 (Brühl, *A.* 200, 186). S.V. 153.86 (Schiff).  $d_4^{20}$  1.406.  $R_D$  53.86. H.F.p. 42.080 (Thomsen); 34.400 (Muller, *Bl.* [2] 44, 609). H.F.v. 38.020 (Th.). H.C. 1,047.100 (gaseous); 1,038.300 (liquid) (M.). *Critical temperature*, 267° (Pawlewsky, *B.* 16, 2633).

**Formation.**—1. By heating diethylamine with  $EtBr$ .—2. From cyanic ether and  $KOEt$ .—3. By heating ammonia with  $EtI$ ,  $EtBr$ ,  $EtCl$ , or  $EtNO_2$ ; v. **ETHYLAMINE** (Hofmann, *C. J.* 3, 300; Carey Lea, *C. N.* 6, 142).—4. Together with ethylene and water by the destructive distillation of tetraethylammonium hydroxide (Hofmann).—5. Together with mono- and di-ethyl-amine, by heating absolute alcohol with ammoniacal  $ZnCl_2$  at 260° (Merz a. Gasiorowski, *B.* 17, 637).

**Properties.**—Strongly alkaline liquid, inflammable, having an ammoniacal odour; sl. sol. water. Its aqueous solution forms with salts of  $Zn$ ,  $Cd$ ,  $Be$ ,  $Zr$ ,  $Ni$ ,  $Co$ ,  $Sn$ ,  $Ag$ ,  $Hg^{II}$ ,  $Cu$ ,  $Pb$ ,  $Fe$ , and  $Mg$ , pps. insol. excess; with salts of  $Al$  and  $Sn^{IV}$  a pp. v. sol. excess; with  $AuCl_3$  it gives a yellow pp. insol. excess, which soon blackens from reduction to  $AuCl$ , an odour of aldehyde being formed.

**Reactions.**—1. At a temperature of 1200° it gives  $HCy$ , ammonia, carbon, hydrogen,  $CH_4$ , acetylene, and  $C_2H_2$ , but no benzene or  $N$  (Muller, *Bl.* [2] 45, 438).—2.  $KMnO_4$  oxidises it, giving  $CO_2$  and  $HOAc$  (Wallach a. Claisen, *B.* 8, 1237).—3. Its hydrochloride is not decomposed by aqueous  $KNO_3$  in the cold, but on boiling some  $NEt_3 \cdot NO$  is formed (Geuther, *Z.* [2] 2, 613).—4. When heated with  $\alpha$ -bromo-butyric acid and water there is formed  $\alpha$ -oxy-butyric acid and  $NEt_3 \cdot HBr$ . The same products appear to be formed when no water is present (Duvillier, *Bl.* [2] 48, 3; cf. Brühl, *B.* 9, 34).—5.  $SO_2$

forms  $Et_3N \cdot SO_2$  [92°] which crystallises in

tables; sol. alcohol, acetone, and hot water; sl. sol. cold water and ether. It is decomposed by boiling water into acid triethylamine sulphate (Beilstein a. Wiegand, *B.* 16, 1267).—6. Triethylamine combines directly with the chlorides, bromides, and iodides of primary alkyls, forming ammonium derivatives that are not decomposed by  $KOH$ , but are converted by moist  $Ag_2O$  into non-volatile, caustic bases. When the alkyl is secondary or tertiary an olefine and a salt of triethylamine are the chief products. Thus, isopropyl iodide at 100° forms  $NEt_3 \cdot HI$  and  $C_3H_8$ , while  $Me_2CBr$  forms  $NEt_3 \cdot HBr$  and butylene (Reboul, *C. R.* 93, 69).

**Salts.**— $B \cdot HCl$ : white, non-deliquescent laminae.— $B \cdot H_2PtCl_6$ : orange monoclinic crystals, v. sol. water.— $B \cdot HAuCl_4$ : monoclinic crystals.— $B \cdot H_2HgCl_4$ : hexagonal crystals (Topsoë).— $B \cdot HHgCl_2$ : monoclinic.— $B \cdot HHgCl_2$ : monoclinic.— $B \cdot H_2CuCl_4$ : monoclinic.— $B \cdot HNO_3$  [90°]. Hygroscopic crystals (Franchimont, *B. T. C.* 2, 388).— $B \cdot H_2PtBr_6$ : monoclinic.— $B \cdot HBiI_4$ : scarlet prisms (Kraut, *A.* 210, 817).— $B \cdot H_2C_2O_4$ : trimetric plates (Loschmidt, *J.* 1865, 875; *Sitz. W.* 51 [2] 7, 884).

**Benzene sulphonate**  $C_6H_5 \cdot SO_3H \cdot$

[121°] (Norton, *Am.* 10, 129).—*p*-Toluene sulphonate  $C_6H_4 \cdot Me \cdot SO_3H \cdot$  [65°] (N.).

**Tetra-ethyl-ammonium hydroxide**  $NEt_4OH$ . Obtained by decomposing its iodide by moist  $Ag_2O$  or its sulphate by baryta. Very deliquescent, hair-like needles. Absorbs  $CO_2$  from the air. Strongly alkaline, saponifying fats. Its solution rubbed between the fingers feels like caustic potash; it strongly attacks the tongue, and when dilute has a bitter taste. With metallic solutions it behaves like potash, except that alumina is less soluble in it, and hydrated chromic oxide is quite insoluble. A very concentrated solution, as well as the dry base, is split up at 103° into  $NEt_3$ , water, and  $C_2H_4$ . Its solution boiled for 24 hours with  $EtI$  gives  $NEt_3I$  and alcohol.

**Salts of Tetraethyl ammonium** (Hofmann, *C. J.* 4, 804; *A.* 78, 253).— $NEt_4Cl$ . The union of  $NEt_3$  with  $EtCl$  takes place with difficulty in dilute alcoholic solutions (Malbot, *A. Ch.* [6] 13, 545).— $(NEt_4)_2PtCl_6$ : orange pp.; sl. sol. water, v. sl. sol. alcohol and ether.— $NEt_4AuCl_4$ : lemon-yellow pp.; sl. sol. cold water and  $HClAq$ .— $(NEt_4)_2Hg_2Cl_6$ : white crystalline pp.; sol. water and boiling  $HClAq$ , from which it separates as unctuous plates (Hofmann).— $(NEt_4)_2HgCl_4$ : dimetric crystals (Topsoë, *J.* 1883, 620).— $NEt_4HgCl_4$ : triclinic.— $NEt_4HgCl_4$ : triclinic.— $NEt_4HgCl_4$ : monoclinic.— $NEt_4HgCl_4$ : hexagonal rhombohedra.— $NEt_4I$ : regular crystals deposited from a hot solution of  $NEt_4Cl$  and  $ICl$  in water (Tilden, *C. J.* 19, 145).— $(NEt_4)_2BiCl_6$ : six-sided tables (Jørgensen, *J. pr.* [2] 3, 344).— $(NEt_4)_2CuCl_4$ : dimetric crystals.— $NEt_4Br$ .— $NEt_4Br$  [78°]: light-red pp. or orange-red needles (from alcohol); v. sol. alcohol and  $CS_2$ . A solution of iodine in aqueous  $KI$  added to its alcoholic solution throws down  $NEt_4I$  (Clamort-Marquart, *J. pr.* [2] 1, 429).— $NEt_4Br$ : crimson pp.; gives off  $\frac{2}{3}$  of its  $Br$  in air.— $(NEt_4)_2BiBr_6$  (Jørgensen).— $NEt_4I$ . The union of  $NEt_3$  with  $EtI$  takes place slowly in the cold, but when it is started at 100° it goes on with great vigour. Large crystals (from water); v. sol. cold water, sol. alcohol, insol. ether. Decomposed on distillation into  $NEt_3$  and  $EtI$ . Not acted on by  $KOHAq$ , but less soluble therein than in water. Decomposed by  $AgNO_3$ , by  $Ag_2SO_4$ , or by moist  $Ag_2O$ , yielding  $NEt_3NO_3$ ,  $(NEt_4)_2SO_4$ , or  $NEt_4OH$  respectively.— $NEt_4I$ : rod needles (Weltzien, *A.* 86, 292; 91, 33).— $NEt_4I$ : [208°]: dark-violet plates (Geuther, *A.* 240, 66).— $(NEt_4)_2HgI_4$ : from  $NEt_4I$  and  $HgI_2$ .— $(NEt_4)_2HgI_4$ : yellow crystals formed by the action of  $EtI$  on  $N_2Hg$ , or  $NHg_2H_2Cl$ ; m. sol. alcohol, not decomposed by water (R. Müller, *A.* 108, 6; Sonnenschein, *A.* 101, 20).— $NEt_4IHgI_2$ : from  $NEt_4I$  and  $Hg$  (Risse, *A.* 107, 224).— $C_2H_5 \cdot N \cdot HgI_2$ : [150°]: from  $NH_4HgCl$  and  $IEt$ : golden-yellow crystals, insol. alcohol, ether, and water.— $(NEt_4)_2BiI_6$  (Jørgensen, *J. pr.* [2] 3, 339).— $(NEt_4)_2W_2O_8$ : deliquescent (Classen, *J. pr.* 93, 446).— $(NEt_4)_2Mo_2O_8$  8aq: deliquescent (C.).— $(NEt_4)_2O_6SnO_2$  aq: insoluble dimetric octahedra.— $(NEt_4)_2O_7SnO_2$  aq.— $(NEt_4)_2CrO_4$ : not crystallised.— $(NEt_4)_2SrO_4$ : prisms (C.).— $NEt_4AsO_4$ : crystalline.— $(NEt_4)_2Sb_2O_8$ : deliquescent (C.).—**Picrate** [251°] (Loosen, *A.* 181, 875).— $(NEt_4)_2FeCy_4$  4aq: from  $Ag_2FeCy_4$  and  $NEt_3I$

(Bernheimer, B. 12, 409).— $\text{NEt}_2\text{VO}_3$  (Bailey, C. J. 45, 688).

**Tri-ethylamine methylo-hydroxide**  
 $\text{NEt}_2\text{Me}(\text{OH})$ . *Methyl-tri-ethyl-ammonium hydroxide*. *Derivatives*:  $\text{NEt}_2\text{MeI}$ . From  $\text{NEt}_2$  and  $\text{MeI}$  (Hofmann, A. 78, 277). V. s. sol. water, but pptd. from its solution by  $\text{KOH}$ .— $\text{NEt}_2\text{MeI}_2$ : [16°]; dark green plates.— $\text{NEt}_2\text{MeI}_3$ : [42°]; brownish-violet plates.— $(\text{NEt}_2\text{MeCl})_2\text{PtCl}_2$ : dimetric crystals.— $\text{NEt}_2\text{MeAuCl}_2$ : dimetric.— $(\text{NEt}_2\text{MeCl})_2\text{HgCl}_2$ : dimetric (Topsoe, Z. K. 8, 246).— $(\text{NEt}_2\text{MeCl})_2\text{HgCl}_2$ : monoclinic.— $\text{NEt}_2\text{MeCl}(\text{HgCl}_2)_2$ : monoclinic crystals.— $(\text{NEt}_2\text{MeCl})_2\text{CuCl}_2$ .— $\text{NEt}_2\text{MeI}_3$  (Müller, A. 108, 5).—Picrate [268°] (Lossen, A. 181, 374).

**Tri-ethylamine iodo-methyl-hydroxide**. *Derivatives*:  $\text{NEt}_2(\text{CH}_2\text{I})\text{I}$ . From  $\text{NEt}_2$  and  $\text{CH}_2\text{I}_2$  (Lermontoff, B. 7, 1253). Dimetric tables, v. sol. water. Boiling with  $\text{Ag}_2\text{O}$  suspended in water gives  $\text{NEt}_2(\text{CH}_2\text{I})\text{OH}$ .— $(\text{NEt}_2\text{CH}_2\text{I})_2\text{PtCl}_2$ : octahedra.

**Tri-ethylamine amilo-hydroxide**  
 $\text{NEt}_2(\text{C}_2\text{H}_5)\text{OH}$ . Not obtained crystalline. The iodide  $\text{NEt}_2(\text{C}_2\text{H}_5)\text{I}$  forms slender unctuous crystals, v. sol. water and alcohol, insol. ether (Hofmann, C. J. 4, 813).

**DI-ETHYLAMINE DISULPHONIC ACID**  
 $\text{C}_2\text{H}_5\text{NS}_2\text{O}_4$  i.e.  $\text{NH}(\text{CH}_2\text{CH}_2\text{SO}_3\text{H})_2$ . *Imido-di-ethane disulphonic acid*. Formed by heating taurine with baryta-water at 220° (Salkowsky, B. 7, 117).

**ETHYL-AMMELINES** *v.* *Cyanuric acid* in the article CYANIC ACID.

**ETHYL-AMYL IS HEPTANE.**

**DI-ETHYL-AMYL-AMINE**  $\text{NEt}_2(\text{C}_2\text{H}_5)$ . (164°). Obtained, together with water and ethylene, by the dry distillation of  $\text{NEt}_2(\text{C}_2\text{H}_5)\text{OH}$  (Hofmann, C. J. 4, 315). Liquid, sol. water.

**ETHYL-ISO-AMYL-ANILINE**  $\text{C}_6\text{H}_5\text{N}$  i.e.  $\text{NPhEt}(\text{C}_2\text{H}_5)$ . Mol. w. 191. (262°). From isoamyl-aniline and  $\text{EtBr}$  or from ethyl-aniline and isoamyl bromide at 100° (Hofmann, A. 74, 156; 79, 13). Liquid. Its hydrobromide is resolved by distillation into ethyl-aniline and isoamyl bromide.  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$  give a product [c. 79°] (Van Romburgh, R. T. G. 2, 103).— $\text{B}^*\text{H}_2\text{PtCl}_2$ : [100°].

*Methylo-iodide*  $\text{NPhEt}(\text{C}_2\text{H}_5)\text{MeI}$ . Moist  $\text{Ag}_2\text{O}$  forms  $\text{NPhEt}(\text{C}_2\text{H}_5)\text{MeOH}$ , which is resolved by distillation into ethylene, water, and methyl-isoamyl-aniline. Gives the platinum-chloride  $(\text{NPhEt}(\text{C}_2\text{H}_5)\text{MeCl})_2\text{PtCl}_2$ .

**DI-ETHYL-ISO-AMYL BORATE**

$\text{Et}(\text{C}_2\text{H}_5)_2\text{BO}_2$  (174°). S.G. 25° 858 (Schiff, A. Suppl. 5, 154).

**Ethyl-di-isoamyl borate**  $\text{Et}(\text{C}_2\text{H}_5)_2\text{BO}_2$  (c. 218°). S.G. 2° 876.

**ETHYL ISO-AMYL CARBONATE**

$\text{Et}(\text{C}_2\text{H}_5)_2\text{CO}_2$  (182° cor.). S.G. 21° 92 (Röse, A. 205, 230).  $\text{PCl}_5$  gives  $\text{C}_2\text{H}_5\text{O.COCl}$  and  $\text{EtCl}$ .

**ETHYL AMYL KETONE**  $\text{C}_2\text{H}_5\text{CO.CEtMe}$ . *Ethyl-amyl-pinacolim*. (151°). S.G. 2° 845; 21° 829. From  $\text{CEtMe.COCl}$  and  $\text{ZnEt}_2$  (Wyschnegradsky, A. 178, 107). Formed also by boiling the pinacone  $\text{CMeEt}(\text{OH}).\text{CMeEt}(\text{OH})$  with diluted  $\text{H}_2\text{SO}_4$  (Lavrionvitch, A. 185, 126). Gives on oxidation acetic acid and  $\text{CEtMe.CO}_2\text{H}$ .

**Ethyl amyl ketone**  $\text{C}_2\text{H}_5\text{CO}$ . (154°). S.G. 241. Occurs among the by-products in the preparation of ether (Hartwig, J. pr. [2] 23, 449). Oil, smelling like camphor. Reduces to a second

dary alcohol  $\text{C}_2\text{H}_5\text{O}$ . Oxidation gives propionic and valeric acids.

**ETHYL ISO-AMYL OXIDE**  $\text{C}_2\text{H}_5\text{O}$  i.e.  $\text{Et.O.C}_2\text{H}_5$ . *Ethyl amyl ether*. (112°). V.D. 4.04. S.G. 18° 764. H.F. 49,000 (Berthelot). Prepared by the action of potassium isoamylate  $\text{KOC}_2\text{H}_5$  on  $\text{EtI}$ ; or of potassium ethylate on isoamyl iodide (Williamson, C. J. 4, 233). Not formed by distilling a mixture of ethyl and isoamyl alcohols, since amylene is given off (Guthrie, A. 105, 37). Oil, lighter than water, smelling like sage.

**Ethyl tert-amyl oxide**  $\text{Et.O.CMeEt}$ . (102°). S.G. 2° 779; 12° 751. A by-product in the formation of amylene by the action of alcoholic potash on tert-amyl iodide: the yield being 2 p.c. (Kondakoff, J. R. 1887, 300; Reboul, C. R. 64, 1243).

**DI-ETHYL-ISO-AMYL-PHOSPHINE**

$\text{Et}_2(\text{C}_2\text{H}_5)_2\text{P}$ . (186°). Formed by treating di-ethyl-isoamyl-phosphine hydrochloride with  $\text{NaIO}_3$ . A colourless slightly viscid liquid (Collie, C. J. 53, 722).

**Tri-ethyl-iso-amyl-phosphonium chloride**. Formed by heating iso-amyl chloride with tri-ethyl phosphine at 130° in a sealed tube (Collie). Very deliquescent. Decomposed above 300° into ethylene and di-ethyl-isoamyl-phosphine hydrochloride  $\text{Et}_2(\text{C}_2\text{H}_5)_2\text{PHCl}$ . The platinum chloride forms thick needles. M. sol. water.

**TRI-ETHYL-ISO-AMYL SILICATE**

$\text{Et}_2(\text{C}_2\text{H}_5)_2\text{SiO}_2$  (216°–225°). From isoamyl alcohol and  $\text{ClSi}(\text{OEt})_2$  (Friedel, A. Ch. [4] 9, 5).

**Di-ethyl-di-isoamyl silicate**  $\text{Et}(\text{C}_2\text{H}_5)_2\text{SiO}_2$  (245°–250°). S.G. 2° 915. From  $\text{Cl}_2\text{Si}(\text{OEt})_2$  and isoamyl alcohol.

**Ethyl-tri-isoamyl silicate**  $\text{Et}(\text{C}_2\text{H}_5)_3\text{SiO}_2$  (280°–285°). S.G. 2° 913. From  $\text{Cl}_3\text{SiOEt}$  and isoamyl alcohol.

**ETHYL-ISO-AMYL SULPHIDE**  $\text{C}_2\text{H}_5\text{S}$  i.e.  $\text{Et.S.C}_2\text{H}_5$ . (160° i.v.) (B.). S.G. 2° 852. From  $\text{NaSC}_2\text{H}_5$  and  $\text{EtI}$ ; or from  $\text{C}_2\text{H}_5\text{I}$  and  $\text{NaSEt}$  in dry alcohol (E. O. Beckmann, J. pr. 125, 449; A. Saytzeff, A. 139, 361). Colourless oil with alliaceous odour.  $\text{MeI}$  at 100° gives  $\text{SMe}_2\text{I}$ , ethyl iodide, and  $\text{C}_2\text{H}_5\text{I}$ .  $\text{HgI}_2$  forms a compound  $\text{HgI}_2\text{SEt}(\text{C}_2\text{H}_5)$ .

**Ethyl-amyl-di-sulphide**  $(\text{C}_2\text{H}_5)(\text{C}_2\text{H}_5)_2\text{S}_2$ . Formed by oxidation of an ethereal solution of ethyl- and amyl-mercaptans with bromine. Thin colourless liquid. Volatile with steam. Lighter than water. Miscible with alcohol and ether, insol. water (Otto, A. Rössing, B. 19, 1314).

**ETHYL-ISO-AMYL SULPHONE**

$\text{Et}(\text{C}_2\text{H}_5)_2\text{SO}_2$  [14°]. (270° i.v.). S.G. 12° 1032. From ethyl-isoamyl sulphoxide (q. v.) and aqueous  $\text{KMnO}_4$  (E. O. Beckmann, J. pr. 125, 450).

**ETHYL-ISO-AMYL SULPHOXIDE**

$\text{Et}(\text{C}_2\text{H}_5)_2\text{SO}$ . From ethyl-isoamyl sulphide (1 pt.) and (2 pts. of)  $\text{HNO}_3$  (S.G. 1.4). Crystalline (Beckmann, J. pr. 125, 449). Oil, solidified by a freezing mixture at –15°. May be reduced to ethyl isoamyl sulphide.

**ETHYL-ISO-AMYL THIOCARBONATE** *v.*

*Ethyl thiocarbonate*.

**ETHYL-ANHYDRACETONE BENZIL** *v.* *ol*. i. p. 462.

**ETHYL-ANILINE**  $\text{C}_6\text{H}_5\text{N}$  i.e.  $\text{NPhEt}$ . Mol. w. 121. (204°). S.G. 12° 954. Formed by heating a mixture of aniline, with excess of  $\text{EtBr}$  to boil-

ing; on cooling, a mass of crystals of its hydrobromide is formed (Hofmann, *C. J.* 3, 285). Prepared by saponifying its acetyl derivative with boiling alcoholic KOH; the acetyl derivative may be obtained by warming alcohol (300 g.), acetanilide (75 g.), KOH (31 g.), and EtBr (65 g.); the reaction is at first violent, and the yield of ethyl-aniline is 41 p.c. of the theoretical (Pictet, *B.* 20, 3422; cf. Hepp, *B.* 10, 327; Elsbach, *B.* 15, 690). Prepared also by heating aniline hydrochloride with ethyl alcohol ( $1\frac{1}{2}$  mol.) for 8 hours at  $150^\circ$ ; the yield being 52 p.c. of the theoretical (Reinhardt a. Staedel, *B.* 16, 29). Commercial ethyl-aniline may be purified by fractional treatment with phthalic anhydride (Piutti, *A.* 227, 181).

**Properties.**—Oil, sol. alcohol, smelling like aniline. Gives no blue colour with bleaching powder solution; colours fir-wood and elder pith less strongly yellow than aniline. Turns brown in air and light.

**Reactions.**—1.  $\text{HNO}_3$  gives off  $\text{CO}_2$  and red fumes, but forms also tetra-nitro-ethyl-aniline (Van Romburgh, *R. T. C.* 2, 31).—2. *Nitrous acid* forms the nitrosamine  $\text{C}_6\text{H}_4\text{NEt}(\text{NO})$ , a heavy yellowish oil, v. sol. alcohol and ether, neutral in reaction, and re-converted into ethyl-aniline by treatment with zinc and dilute  $\text{H}_2\text{SO}_4$  (Griess, *B.* 7, 218).—3. A solution of acetone saturated with  $\text{SO}_2$  forms large crystals of  $\text{C}_6\text{H}_4\text{OSO}_2\text{NPhEtH}$  (Boessneck, *B.* 21, 1906).—4. Its phenyl-ethyl-phthalamate loses  $\text{H}_2\text{O}$  at  $200^\circ$ , becoming  $\text{CO} < \text{C}_6\text{H}_4 > \text{C}(\text{NPhEt})_2$  (Piutti, *A.* 227, 181).—5. *Cyanogen chloride* forms  $\text{PhNEtCy}$  ( $271^\circ$ ) (Cloëz a. Cahours, *A.* 90, 94).

**Salts.**— $\text{B}^+\text{HBr}^-$ : large trimetric tables (from alcohol); v. e. sol. water (Hjortdahl, *Z. K.* 6, 473).— $\text{B}^+\text{H}_2\text{PtCl}_6^-$ : long needles; v. sol. water and alcohol.— $\text{B}^+\text{HCl}^-$ : crystalline mass; converted at  $320^\circ$  into the hydrochloride of amido-phenyl-ethane  $\text{C}_6\text{H}_4\text{Et.NH}_2$  (Hofmann, *B.* 7, 526).— $\text{B}^+\text{HBrCdBr}_2^-$ : trimetric.— $\text{B}^+\text{H}_2\text{SnBr}_3^-$ : monoclinic.— $\text{B}^+\text{HI}^-$ : trimetric tables.—Ethyl sulphate  $\text{B}^+\text{HEtSO}_4\text{Et}_2\text{SO}_4^-$ : prisms: from  $\text{NPhEtH}$  and  $\text{Et}_2\text{SO}_4$  in benzene (Claesson a. Lundwall, *B.* 13, 1704).

**Formyl derivative**  $\text{C}_6\text{H}_4\text{NEtCHO}$ . ( $260^\circ$ ). S.G.  $d_4^{20}$  1.063 (Pictet a. Crépieux, *B.* 21, 1106; cf. Tobias, *B.* 15, 2866).

**Acetyl derivative**  $\text{C}_6\text{H}_4\text{NAcEt}$ . ( $55^\circ$ ). ( $249^\circ$ ); ( $258^\circ$ ) at 731 mm. (P. a. O.). From sodium acetanilide and  $\text{EtI}$ . Also from di-ethyl-aniline and  $\text{AcBr}$ . Prisms; sol. ether (Elsbach, *B.* 15, 690; Staedel, *B.* 16, 29; 19, 1948).

**Benzoyl derivative**  $\text{C}_6\text{H}_4\text{NEtBz}$ . ( $60^\circ$ ); large crystals; v. sol. alcohol, ether, &c., insol. water. Formed by heating di-ethyl-aniline with benzoyl chloride at  $200^\circ$  (Hess, *B.* 18, 687).

**Di-ethyl-aniline**  $\text{C}_6\text{H}_4\text{N}$  i.e.  $\text{C}_6\text{H}_4\text{NEt}_2$ . Mol. w. 149. ( $214^\circ$ ). S.G.  $d_4^{20}$  0.936. S.H. 476 between  $8^\circ$  and  $80^\circ$  (R. Schiff, *G.* 17, 286). Formed by heating ethyl-aniline with excess of EtBr (Hofmann, *A.* 74, 135). Prepared by heating aniline hydrobromide (or hydroiodide) with ( $2\frac{1}{2}$  mols. of) ethyl alcohol to  $160^\circ$  for 8 hours; the yield is 98 p.c. of the theoretical (Reinhardt a. Staedel, *B.* 16, 29).

**Properties.**—Oil. Gives no colour with bleaching powder. Does not turn brown in air. Benzoyl chloride at  $180^\circ$  forms EtCl and benzoyl-

ethyl-aniline (Hess, *B.* 18, 687).  $\text{AcBr}$  forms EtBr and  $\text{NPhEtAc}$  (Staedel, *B.* 19, 1948).  $\text{HNO}_3$  forms tetra-nitro-ethyl-aniline (Van Romburgh, *R. T. C.* 2, 31). Nitrous acid gives nitroso-di-ethyl-aniline  $\text{C}_6\text{H}_4(\text{NO})\text{NEt}_2$ , which crystallises from ether in green prisms [ $84^\circ$ ], and dissolves in dilute acids.

**Salts.**— $\text{B}^+\text{HBr}^-$ : four-sided tables; sublimes in needles.— $\text{B}^+\text{H}_2\text{PtCl}_6^-$ : yellow prisms (from alcohol); less soluble than the platinumchloride of ethyl-aniline.— $\text{B}^+\text{H}_2\text{Cl}_2\text{SnBr}_3^-$ : monoclinic prisms (Hjortdahl, *J.* 1882, 524).— $\text{B}^+\text{H}_2\text{Br}_2\text{SnBr}_3^-$ .

**Methylo-iodide**  $\text{B}^+\text{MeI}^-$ : [ $102^\circ$ ]; identical with methyl-ethyl-aniline ethylo-iodide. By treatment with KOH it gives methyl-ethyl-aniline (Claus a. Howitz, *B.* 17, 1326). The corresponding hydroxide splits up on distillation into ethylene, water, and di-ethyl-aniline. Its salts are: ( $\text{NPhEt}_2\text{Cl}$ ),  $\text{PtCl}_4$ — $\text{NPhEt}_2\text{I}$ , [ $81^\circ$ ].  $\text{NPhEt}_2\text{I}$ , [ $68^\circ$ ] (Dafert, *M.* 4, 502).

**Ethylo-iodide**  $\text{NPhEt}_2\text{I}$ — $\text{NPhEt}_2\text{OH}$ .— $\text{NPhEt}_2\text{Cl}$ .—( $\text{NPhEt}_2\text{Cl}$ ),  $\text{PtCl}_4$  (Hofmann, *A.* 79, 2).

**References.**—BROMO-, CHLORO-, CHLORO-NITRO-, and NITRO-ETHYL-ANILINE.

**ETHYL-ANILINE AZYLINYL v. Di-ethyl-amido-benzene-Azo-di-ethyl-aniline.**

**ETHYL-ANILINE SULPHONIC ACID** a. ETHYL-AMIDO-BENZENE SULPHONIC ACID.

**ETHYL-ANTHRACENE**  $\text{C}_{14}\text{H}_{10}$ , or  $\text{C}_6\text{H}_4 < \text{C}(\text{C}_6\text{H}_4) > \text{C}_6\text{H}_4$ . [ $61^\circ$ ]. Large plates.

Prepared by reduction of ethyl-oxanthranol with zinc-dust and  $\text{NH}_3$  (Liebermann a. Tobias, *B.* 14, 802; *A.* 212, 109). Picric acid compound [ $120^\circ$ ].

**ETHYL-ANTHRACENE-DIHYDRIDE**  $\text{C}_{14}\text{H}_{12}$ , or  $\text{C}_6\text{H}_4 < \text{CHEt} > \text{C}_6\text{H}_4$ . ( $322^\circ$  cor.). S.G.  $d_4^{20}$  1.049.

Prepared by reduction of ethyl-oxanthranol with P and HI (S.G. 1.7) (Liebermann, *B.* 13, 1600; *A.* 212, 76). Clear fluorescent liquid. Miscible with alcohol, ether, benzene, and acetic acid in all proportions. Cautious treatment with  $\text{CrO}_3$  in glacial acetic acid reconverts it into ethyl-oxanthranol; further oxidation gives anthraquinone.

**Di-ethyl-anthracene dihydride**

$\text{C}_6\text{H}_4 < \text{C}(\text{Et})_2 > \text{C}_6\text{H}_4$ . [ $50^\circ$ ]. From di-ethyl-anthrone,  $\text{HIAq}$  (S.G. 1.7), and amorphous phosphorus at  $190^\circ$  (Goldmann, *B.* 21, 1176). Colourless crystals, v. sol. ligroin, ether, and  $\text{CS}_2$ . Oxidised by  $\text{CrO}_3$  in  $\text{HOAc}$  to di-ethyl-anthrone.

**Ethyl-anthracene-hydride-nitrite**  $\text{C}_{14}\text{H}_{10}(\text{O}_2\text{N})_2$ . [ $130^\circ$ ]. Large crystals. Sol. benzene. Prepared by the action of  $\text{HNO}_3$  on an acetic acid solution of ethyl-anthracene-hydride. On oxidation with  $\text{CrO}_3$  it gives anthraquinone (Liebermann a. Landshoff, *B.* 14, 473).

**ETHYL-ANTHRANOL** *Ethyl ether*

$\text{C}_6\text{H}_4 < \text{C}(\text{OEt}) > \text{C}_6\text{H}_4$ . [ $77^\circ$ ]. Formed by the action of ethyl iodide and KOH on anthranol (Goldmann, *B.* 21, 2506). Needles (from dilute alcohol); v. e. sol. benzene, ether, and petroleum ether. Oxidised by chromic acid to ethyl-oxanthranol  $\text{C}_6\text{H}_4 < \text{C}(\text{OOH}) > \text{C}_6\text{H}_4$ . [ $106^\circ$ ].

DI-ETHYL-ANTHRONE  $C_{18}H_{16}O$  *i.e.*

$C_6H_5 \begin{smallmatrix} \diagup CO \\ \diagdown OEt \end{smallmatrix} C_6H_5$ . Formed together with the ethyl derivative of anthranol

$C_6H_5 \begin{smallmatrix} \diagup O(OEt) \\ \diagdown CH \end{smallmatrix} C_6H_5$  by boiling anthranol with

conc. KOH aq and EtI (Goldmann, *B.* 21, 1176). [186°]. Colourless crystals, v. sol. benzene, chloroform, alcohol, and ether, sol. ligroin, insol. aqueous alkalis. Oxidised by  $CrO_3$  in HOAc to anthraquinone. Does not combine with Br. Not affected by HCl in HOAc at 180°.

**ETHYL ARSENATE**  $(C_2H_5)_2AsO_4$ . (237°). S.G. 2 1.326. Decomposed by water into alcohol and arsenic acid (Crafts, *Bl.* [2] 14, 99).

**ETHYL ARSENITE**  $(C_2H_5)_2AsO_3$ . (166°). S.G. 2 1.224. Formed from  $Ag_3AsO_3$  and EtI. Prepared by the action of NaOEt on  $AsCl_3$  or  $AsBr_3$  in alcoholic solution. Only  $\frac{1}{2}$  of the calculated quantity of NaOEt is used, to avoid saponification of the ether. Excess of  $AsBr_3$  is removed by passing in dry  $NH_3$  and filtering from the pp. Arsenious ether is also formed by heating  $Et_2SiO_3$  with  $As_2O_3$  at 200°. It is not affected by dry  $NH_3$ , but is decomposed by water into alcohol and  $As_2O_3$ . HBr gives alcohol and  $AsBr_3$  (Crafts, *Bl.* [2] 14, 99).

**ETHYL-ARSENES v. ARSENIC, ORGANIC COMPOUNDS OF.**

**ETHYLATION OF BASES.** The displacement of hydrogen by ethyl in primary and secondary bases is usually effected by heating with ethyl iodide (bromide or chloride), the resulting compound being decomposed by potash. Another method consists in heating the hydrochloride (hydrobromide or hydroiodide) of the base with 10 p.c. more than the calculated quantity of ethyl alcohol at 150° for 8 hrs.; the yield varies from 28 p.c. to 99 p.c. of the theoretical, according to the base. The reaction takes place most readily with the iodide, and least readily with the chloride (cf. Reinhardt & Staedel, *B.* 16, 29).

**ETHYL-ATROLACTIC ACID v. Ethyl derivatives of  $\alpha$ -Oxy- $\alpha$ -PHENYL-PROPIONIC ACID.**

**ETHYL-ATROPINE v. ATROPINE.**

**ETHYL-AZAUROLIC ACID v. AZAUROLIC ACID.**

**ETHYL-BARBITURIC ACID v. Ethyl derivatives of BARBITURIC ACID.**

**ETHYL-BENZENE**  $C_8H_{10}$ , *i.e.*  $C_2H_5 \cdot C_6H_5$ . Mol. w. 106. (186° 1 V.). S.G. 2 0.8673 (Brühl, *A.* 235, 12); 2 0.8760 (Schiff, *A.* 220, 92). C.E. (9.9° to 135.8°) -0.0129. V.D. 3.65 (calc. 3.66). S.V. 158.9.  $\mu_D$  1.496. S.H. 393 at 0° (Schiff, *A.* 234, 300).

**Occurrence.**—In Dippel's oil (Weidel & Ciamician, *B.* 13, 70).

**Formation.**—1. From EtBr,  $C_6H_5Br$  and Na (Fittig, *A.* 131, 810; 133, 222; 144, 278).—2. From benzene,  $Al_2Cl_6$  and EtCl or ethylene (Friedel & Crafts, *A. Ch.* [6] 1, 457; 14, 456; Rennie, *C. J.* 41, 33; Balsohn, *Bl.* [2] 31, 540; Söllscher, *B.* 15, 1680).—3. By heating benzene (4 pts.) with ether (1 pt.) and  $ZnCl_2$  (2 pts.) for 12 hours at 180° (Balsohn, *Bl.* [2] 32, 617).—4. According to Berthelot (*Bl.* [2] 9, 289) it is among the products obtained by heating naphthalene with conc. HIAc (20 pts.).—5. Accord-

ing to Friedel & Crafts (*Bl.* [2] 39, 195) it is among the carbonaceous products of the action of  $Al_2Cl_6$  on benzene at 200°.—6. By heating styrene with HIAc (20 pts.) (Berthelot, *Bl.* [2] 9, 455).

**Properties.**—Liquid, resembling toluene.

**Reactions.**—1. On passing through a red-hot tube it is decomposed forming styrene (2 p.c.) benzene (15 p.c.), toluene (1 p.c.), naphthalene (2.2 p.c.), naphthalene dihydride, diphenyl (6 p.c.), phenanthrene (2.6 p.c.), and anthracene (4 p.c.) (Berthelot, *Z.* [3] 4, 689; Ferkö, *B.* 20, 663).—2. By prolonged oxidation with dilute  $HNO_3$  or  $CrO_3$  it is converted into benzoic acid. When the oxidation is incomplete there is formed a small quantity (10 p.c.) of acetophenone (Friedel & Balsohn, *Bl.* [2] 32, 615).—3. In carbon disulphide it yields with chromyl chloride  $CrO_2Cl_2$  a chocolate crystalline pp. of composition  $PhEt_2CrO_2Cl_2$  converted by moisture into phenylacetic aldehyde (Étard, *A. Ch.* [5] 22, 246).—4. Converted by boiling with  $Al_2Cl_6$  into *p*-di-ethylbenzene and a little *m*-di-ethylbenzene (Anschütz, *A.* 235, 189).—5. Chlorine under the influence of light forms  $\alpha$ -chloro-ethylbenzene (Schramm, *M.* 8, 101).—6. By the action of bromine in the dark, or of bromine in presence of 3 p.c. of iodine in diffused daylight it yields a mixture of *o*- and *p*-bromo-ethylbenzene (Schramm, *B.* 18, 1272; *M.* 8, 304).

***m*-Di-ethylbenzene.** [ $-20^\circ$ ]. (182°). S.G. 2 0.8602. Formed, together with the *p*-isomeride, when benzene is acted upon by EtBr in presence of  $AlCl_3$  (Voswinkel, *B.* 21, 2829). Forms no compound with picric acid. Dilute  $HNO_3$  gives isophthalic acid. Gives  $C_6H_5BrEt$ , (238°) and  $C_6Br_2Et$ , (74°).

***p*-Di-ethylbenzene**  $C_{10}H_{14}$ , *i.e.*  $C_2H_5(C_2H_5)_2$ . Mol. w. 134. (181°) (A.). S.G. 1.5 0.871.

**Formation.**—1. From *p*-di-bromo-benzene [89°] by treatment with sodium and EtI (Aschenbrandt, *A.* 216, 212; *B.* 12, 1303).—2. From *p*-bromo-ethylbenzene, Na and EtI (Fittig, *A.* 144, 285).—3. A di-ethylbenzene (179°–185°) is formed by passing ethylene into benzene containing  $Al_2Cl_6$  (Balsohn, *Bl.* [2] 31, 540; Friedel & Crafts, *A. Ch.* [6] 14, 456).—4. By passing EtCl into benzene containing  $Al_2Cl_6$  a di-ethylbenzene is formed which on oxidation by chromic mixture gives an acid  $C_8H_7(CO_2H)_2$ ,  $CH_3CO_2H$  subliming at 210° (Allen & Underwood, *Bl.* [2] 40, 100).

**Reactions.**—1. Gives ethylbenzoic acid on oxidation by dilute  $HNO_3$ . Chromic acid mixture forms terephthalic acid.—2.  $CrO_2Cl_2$  forms a compound  $C_6H_5Et_2CrO_2Cl_2$  converted by water into phenylacetic aldehyde (Étard, *A. Ch.* [5] 22, 252).

***s*-Tri-ethylbenzene**  $C_{11}H_{16}$ , *i.e.*  $C_2H_5Et$ , [13.5]. (218°). Formed by treating a mixture of acetone and methyl ethyl ketone with  $H_2SO_4$  (Jacobsen, *B.* 7, 1480). It yields trimelic acid  $C_6H_2(CO_2H)_3$  on oxidation. Tri-ethylbenzenes are also formed by the action of ethylene on benzene in presence of  $Al_2Cl_6$  (Friedel & Crafts, *A. Ch.* [6] 14, 456), the chief product being *s*-tri-ethylbenzene. On oxidation by  $CrO_3$  this mixture gives an acid  $C_{10}H_8O_4$  crystallising in large needles, and ultimately trimelic acid (Friedel & Balsohn, *Bl.* [2] 34, 638).

**s-Tetra-ethyl-benzene**  $C_6H_4Et_4$  [1:2:4:5]. [18°]. (250°). Formed, together with the consecutive isomeride, by the action of  $EtBr$  and  $AlCl_3$  on benzene; the product (250°-255°) is treated with  $ClSO_3H$ , and the sodium salts of the resulting sulphonic acids crystallised from water. The Na salt of *s*-tetra-ethyl-benzene sulphonic acid crystallises first, and the residual acid is converted into Ba salt. After barium *c*-tetra-ethylbenzene sulphonate has crystallised, there may still be obtained from the mother-liquor a sulphamide [100°], possibly belonging to *i*-tetra-ethyl-benzene. The sulphonic acids are hydrolysed (Jacobsen, *B.* 21, 2820). Crystalline mass; oxidised by dilute  $HNO_3$  and by  $KMnO_4$  to pyromellitic acid. 'Br gives  $C_6Br_4Et_4$  [112.5°].

**c-Tetra-ethyl-benzene**  $C_6H_4(C_2H_5)_4$  [1:2:3:4]. (254° cor.). V.D. ( $H=1$ ) 189.5 (obs.). Colourless liquid. Lighter than water. Prepared by heating benzene with ethyl bromide and  $AlCl_3$  at 100°. On oxidation with  $KMnO_4$ , it gives prehnitic acid  $C_6H_4(CO_2H)_4$  (Galle, *B.* 16, 1745). Forms  $C_6Br_4Et_4$  [77°] (J.).

**Penta-ethyl-benzene**  $C_6H_3Et_5$ . (277°). S.G. 1.8985. Obtained from benzene by the action of  $EtBr$  and  $AlCl_3$ . Purified by conversion into the sulphonic acid by  $ClSO_3H$ , crystallisation of the Na salt, and subsequent hydrolysis (Jacobsen, *B.* 19, 1209; 20, 896, 2857; 21, 2814). Oil. Does not solidify at -20°.  $HNO_3$  does not give a nitro-compound. When treated with conc.  $H_2SO_4$ , followed by fuming  $H_2SO_4$ , there is formed  $C_6H_3Et_5$  and  $C_6Et_6$ .

**Hexa-ethyl-benzene**  $C_6(C_2H_5)_6$ . [123°]. (298° cor.). V.D. ( $H=1$ ) 242.1 (obs.). Formed by heating benzene with ethyl bromide and  $AlCl_3$  at 100° (Galle, *B.* 16, 1745; Jacobsen, *B.* 21, 2820). Formed also by passing  $EtCl$  into benzene containing  $AlCl_3$  (Albright, Morgan, & Woolworth, *C. R.* 86, 887). Long colourless monoclinic crystals. Sol. alcohol and ether, sl. sol. acetic acid. Easily sublimes.

**References.**—BROMO-, BROMO-NITRO-, CHLORO-, CHLORO-NITRO-, NITRO-, &c., ETHYL-BENZENE.

**ETHYL-BENZENE CARBOXYLIC ACID v. PHENYL-PROPIONIC ACID.**

**Ethyl-benzene di-carboxylic acid**  $C_6H_4O_4$ , i.e.  $CO_2H.C_6H_4.CHMe.CO_2H$ . [147°]. From its nitrile and fuming  $HCl$  at 200° (Gabriel, *B.* 20, 2504). Crystalline powder.

Nitrile  $CN.C_6H_4.CHMe.CN$ . [37°]. (285°). From  $CN.C_6H_4.CH_2CN$  by treatment with alcoholic  $KOH$  and  $MeI$ . Triclinic prisms (Fock, *B.* 20, 2501). V. sol. alcohol and ether. Conc.  $H_2SO_4$  at 125° converts it quickly into the imide  $C_6H_4<\begin{smallmatrix} CHMe.CO \\ CO-NH \end{smallmatrix}$  [145°], whence  $POCl_3$  at 200° gives chloro-oxy-methyl-isoquinoline.

**Isomeride v. CARBOXY-PHENYL-PROPIONIC ACID.**

**ETHYL-BENZENE SULPHONIC ACID**  $C_6H_5Et(SO_3H)$ . Two acids of this composition are obtained by digesting ethyl-benzene with fuming  $H_2SO_4$  at 100°. The more abundant acid forms the less soluble K salt, which crystallises well and yields an amide [108°]; fused with  $KOH$  it yields solid ethyl-phenol (Chrutschoff, *B.* 7, 1166).

**m-Ethyl-benzene sulphonic acid**  $C_6H_4Et(SO_3H)$  [1:3:4:7]. From the hydrocarbon and  $ClSO_3H$  (Voswinkel, *B.* 21, 2880).— $KA'$ : aq:

dimetric tables.— $BA'$ , 5aq: prisms, m. sol. water.— $CUA'$ , 4aq: blue plates.

**Amide**  $C_6H_5Et(SO_2NH_2)$ : [102°]; needles (from alcohol).

**p-Di-ethyl-benzene sulphonic acid**  $C_6H_4Et_2(SO_3H)$ . From di-ethyl-benzene and fuming  $H_2SO_4$  (Fittig & König, *A.* 144, 277; Aschenbrandt, *A.* 216, 214; Remsen & Noyes, *Am.* 4, 200). Deliquescent laminae.

**Salts.**— $KA'$ , 3½aq.— $NA'$ .— $BA'$ , 4aq: leaflets. S. (of  $BA'$ ) 5:1 at 23°.— $SrA'$ , 4aq.— $CA'$ , 5aq.— $CUA'$ , 6aq: blue plates.— $PbA'$ , 3aq.— $HgA'$ .— $NiA'$ , 5aq.— $CoA'$ , 5aq.— $MgA'$ .— $AgA'$ .

**Amide**  $C_6H_4Et_2(SO_2NH_2)$ . [97.5° cor.] Leaflets, sl. sol. water.

**s-Tetra-ethyl-benzene sulphonic acid**  $C_6H_2Et_4(SO_3H)$ . From *s*-tetra-ethyl-benzene and  $ClSO_3H$  (Jacobsen, *B.* 21, 2820).— $NA'$ , 4aq: plates (from water), or tables (from alcohol); sl. sol. cold water, insol. dilute  $NaOHAq$ .— $BA'$ , 4aq: scaly crystalline pp. Sl. sol. boiling water.

**Amide**  $C_6H_2Et_4(SO_2NH_2)$ : [122°]; trimetric plates (from dilute alcohol).

**c-Tetra-ethyl-benzene sulphonic acid**  $C_6H_2Et_4(SO_3H)$ . Silky plates or long needles. Formed by sulphonation of *c*-tetra-ethyl-benzene.

**Salts.**— $NA'$ , 5aq: microscopic plates.— $A'$ , Ba 6aq: flat prisms.— $A'$ , Cu 8aq: light-blue plates.— $A'$ , Cd 7aq: large flat prisms.

**Amide**  $C_6H_2Et_4(SO_2NH_2)$ : [107°]; glistening scales or large monoclinic prisms, v. sol. alcohol and acetic acid, sl. sol. petroleum-ether (Galle, *B.* 16, 1745).

**Penta-ethyl-benzene sulphonic acid**  $C_6H_3Et_5(SO_3H)$ . From penta-ethyl-benzene and  $ClSO_3H$  (Jacobsen, *B.* 21, 2814).— $NA'$ , 4aq: thin pearly plates (from water); m. sol. cold water, insol. dilute  $NaOHAq$ , v. sol. alcohol.— $KA'$ , 2aq: six-sided, trimetric plates (from water), prisms (from alcohol); sl. sol. cold, m. sol. hot, water, v. e. sol. alcohol.— $NH_4A'$ : trimetric, six-sided plates, sl. sol. cold water.— $BA'$ , 9aq: from the Na salt and  $Ba(OAc)_2$ . Small scales; v. sl. sol. boiling water.

**Reference.**—CHLORO-ETHYL-BENZENE SULPHONIC ACID.

**ETHYL-BENZHYDROXAMIC ETHER v. BENZENYL-ETHOXIM ETHYL ETHER.**

**TETRA-ETHYL-BENZIDINE v. TETRA-ETHYL-DI-AMIDO-DIPHENYL.**

**ETHYL BENZOATE v. Ethyl ether of BENZOIC ACID.**

**o-ETHYL-BENZOIC ACID**  $C_6H_5O_4$ , i.e.  $C_6H_4EtCO_2H$  [1:2]. Mol. w. 150. [68°]. Formed by reduction of tri-chloro-, or di-chloro-bromo-, vinyl-benzoic acid with sodium amalgam (Zincke, *B.* 20, 2056). Formed also by reduction of acetophenone carboxylic acid or of phthalyl-acetic acid  $C_6H_4(CO_2H)_2$  with  $HI$  and  $P$  at 180° (Gabriel & Michael, *B.* 10, 2206).—Slender flat needles.— $AgA'$ : long needles.

**m-Ethyl-benzoic acid**  $C_6H_4EtCO_2H$  [1:3]. [47°]. Formed by oxidising *m*-di-ethyl-benzene with dilute  $HNO_3$  (Jacobsen, *B.* 21, 2820). Needles, insol. cold water.— $CA'$ , 4aq: needles, v. sol. water.

**p-Ethyl-benzoic acid**  $C_6H_4EtCO_2H$  [1:4]. [118°].

**Formation.**—1. By the action of sodium and  $CO_2$  upon *p*-bromo-ethyl-benzene (Kekulé, *A.*

187, 178; Kekulé & Thorpe, *C. J.* 22, 366).—  
2. By oxidising di-ethyl-benzene with boiling dilute  $\text{HNO}_3$  (Fittig & König, *A.* 144, 277; Aschenbrandt, *A.* 216, 218).

**Properties.**—Small plates (from water) or prisms (from alcohol), v. sl. sol. cold water, v. sol. alcohol, ether, chloroform, and benzene. May be sublimed. Melts under water. Gives terephthalic acid on oxidation.

**Salts.**— $\text{BaA}'$ , 2aq (A).— $\text{BaA}'_2$  aq (F. & K.).  
S. 2.— $\text{CaA}'$ , 3aq (A).— $\text{CaA}'_2$ , 2aq (F. & K.): feathery tufts of needles.— $\text{CuA}'$ , 2aq.— $\text{AgA}'$ : needles (from hot water).

**Di-ethyl-benzoic acid**  $\text{C}_8\text{H}_{10}\text{O}_2$  i.e.  $\text{C}_6\text{H}_5\text{Et}.\text{CO}_2\text{H}$ . Formed, together with benzoic acid, by fusing di-ethyl-carbobenzoic acid  $\text{C}_{10}\text{H}_{12}\text{O}_2$  with potash (Zagoumenny, *A.* 184, 171). Oil.— $\text{AgA}'$ : laminae (from water).

**References.**—CHLORO- and NITRO- ETHYL-BENZOIC ACIDS.

**ETHYL-BENZOPHENONE** v. PHENYL-ETHYL-PHENYL-KETONE.

**ETHYL-BENZOYL-ACETIC ACID** v. BENZOYL-ACETIC ACID.

**ETHYL-BENZYL-** v. BENZYL-ETHYL.

**ETHYL-DIBENZYL** v. PHENYL-ETHYL-PHENYL-ETHANE.

**ETHYL-DI-BENZYL-PHOSPHINE**

$\text{EtP}(\text{C}_6\text{H}_5)_2$  (320°-330°). Formed by treating with NaOH the distillate from  $\text{Et}_2\text{P}(\text{C}_6\text{H}_5)_2\text{Cl}$  (v. *infra*) (Collie, *C. J.* 53, 725).

**Benzoyl-chloride**  $\text{EtP}(\text{C}_6\text{H}_5)_2\text{Cl}$  aq. Decomposed on distillation, giving ethylene, stilbene, HCl, &c.

**Di-ethyl-benzyl-phosphine**  $\text{Et}_2\text{PC}_6\text{H}_5$  (250°-255°). Formed by distilling  $\text{Et}_2\text{PC}_6\text{H}_5\text{Cl}$  and treating the resulting  $\text{Et}_2\text{PC}_6\text{H}_5\text{ClH}$  with NaOH (Collie, *C. J.* 53, 724).

**Oxide**  $\text{Et}_2(\text{C}_6\text{H}_5)\text{PO}$  (320°). Formed as above, and also by heating  $\text{Et}_2(\text{C}_6\text{H}_5)\text{POH}$ . Long needles. Converted by Na into  $\text{Et}_2\text{PC}_6\text{H}_5$ .

**Sulphide**  $\text{Et}_2(\text{C}_6\text{H}_5)\text{PS}$  (95°). (300°-310°). Formed by adding S to an ethereal solution of  $\text{Et}_2\text{PC}_6\text{H}_5$ . Crystalline; insol. water. When heated with Na the phosphine  $\text{Et}_2\text{PC}_6\text{H}_5$  is liberated.

**Benzoyl-chloride**  $\text{EtP}(\text{C}_6\text{H}_5)_2\text{Cl}$ . Decomposed on heating into  $\text{C}_2\text{H}_4$  and  $\text{EtP}(\text{C}_6\text{H}_5)_2\text{ClH}$ .

**ETHYL BENZYL SULPHIDE** v. *Ethyl derivative of BENZYL MERCAPTAN*.

**TRI-ETHYL-BISMUTHINE** v. BISMUTH-TRI-ETHIDE.

**TRI-ETHYL-BIURET**  $\text{C}_6\text{H}_5\text{N}_2\text{O}_2$  i.e.  $\text{NEt}(\text{CONHEt})_2$ . Formed by warming cyanuric ether with baryta (Limpricht & Habich, *A.* 100, 104; Nencki, *B.* 9, 1011). Thick oil, sl. sol. water, v. sol. alcohol and ether. Split up on distillation into cyanic ether and di-ethyl-urea.

**ETHYL BORATES.**

**Ethyl ortho-borate**  $(\text{C}_2\text{H}_5)_2\text{BO}_2$  (120° i.v.). S.G. 1.087;  $d_4^{20}$  0.861. V.D. 5.14 (calc. 5.07). Prepared by the action of alcohol on  $\text{BCl}_3$  (Ebelmen & Bouquet, *A. Ch.* [3] 17, 55; Bowman, *P. M.* [8] 29, 646). Formed also by distilling a mixture of dry  $\text{K}_2\text{EtSO}_4$  with anhydrous borax (Rose, *P.* 98, 245), and by the action of absolute alcohol as powdered  $\text{B}_2\text{O}_3$  (Schiff, *Bl.* [2] 5, 872; 6, 86). Colourless liquid with alcoholic odour. Burns with green flame. Mixes with ether and

alcohol. Decomposed by water in a few minutes into alcohol and boric acid.  $\text{HNO}_3$  gives nitric ether and boric acid. Acetic acid forms acetic ether and  $\text{B}_2\text{O}_3$ .  $\text{PCl}_5$  forms  $\text{EtCl}$ ,  $\text{POCl}_3$  and  $\text{EtBO}_2$ .

**Ethyl metaborate**  $\text{EtBO}_2$ . Among the products of the action of alcohol on  $\text{B}_2\text{O}_3$ . Dense liquid, absorbs moisture from the air, being split up into alcohol and boric acid. Gives with alcohol  $\text{Et}_2\text{BO}_2$ . Acetic acid at 190° gives acetic ether and  $\text{HBO}_2$ . Cannot be distilled, for it splits up at high temperatures into  $\text{Et}_2\text{BO}_2$  and gummy  $\text{EtB}_2\text{O}_3$ , which behaves like  $\text{EtBO}_2$  towards water and alcohol.

**ETHYL-BORIC ETHER**  $\text{EtB}(\text{OEt})_2$ . The compound  $\text{EtB}(\text{OEt})_2.\text{B}(\text{OEt})_3$  (112°) is formed by action of  $\text{ZnEt}_2$  (2 mols.) on boric ether (1 mol.). Water decomposes it into ethyl-boric acid  $\text{BEt}(\text{OH})_2$  and alcohol (Frankland, *Pr.* 25, 165).

**Di-ethyl-boric ether**  $\text{Et}_2\text{B}.\text{OEt}$  (103°). From  $\text{ZnEt}_2$  and  $\text{EtB}(\text{OEt})_2.\text{B}(\text{OEt})_3$ . Dry oxygen converts it into  $\text{BEt}(\text{OEt})_2$ . Water converts it into diethyl-boric acid  $\text{Et}_2\text{B}.\text{OH}$ , which absorbs oxygen from air, forming crystals of  $\text{Et}_2\text{B}(\text{OEt})_2.\text{OH}$ , whence  $\text{H}_2\text{O}$  forms alcohol and  $\text{EtB}(\text{OH})_2$ .

**ETHYL BROMIDE**  $\text{C}_2\text{H}_5\text{Br}$ . *Bromo-ethane*. Mol. w. 109. (38.4°). S.G.  $\frac{4}{5}$  1.4189 (Mendelejeff); 1.4555 (Weegman, *Z. P. C.* 2, 218);  $\frac{1}{2}$  1.4499;  $\frac{3}{4}$  1.4325. M.M. 5.551 at 19.7°. S.V. 77.07° (Schiff). *Critical temperature*: 236° (Pawlewsky, *B.* 16, 2633).

**Formation.**—1. The rate of formation from alcohol and HBr has been studied by Villiers (*C. R.* 90, 1488).—2. When a mixture of ethylene and HBr is passed over  $\text{AlBr}_3$ , there is formed  $\text{AlBr}_3.\text{C}_2\text{H}_5$ , ethyl bromide, and saturated hydrocarbons (Gustavson, *J. pr.* [2] 34, 161).—3. Together with other products by heating alcohol (1 pt.) with bromine (3 pts.) (Löwig, *A.* 8, 231).

**Preparation.**—1. By adding bromine (8 pts.) gradually to alcohol (40 pts.), mixed with clear phosphorus (1 pt.), and distilling (Serullas, *A. Ch.* 34, 99). Personne (*C. R.* 52, 468) employed red phosphorus (40 g.) with dry alcohol (160 g.) and bromine (100 g.).—2. By mixing  $\text{H}_2\text{SO}_4$  (10 pts.) and alcohol (5 pts.), allowing to stand for some time, and then diluting with water (3 pts.), adding KBr (5 pts.) and distilling. The yield is 80 to 100 p.c. (De Vrij, *J. Ph.* [3] 31 169; cf. *C. J.* 36, 127; *D. P. J.* 229, 284).

**Properties.**—Colourless liquid with ethereal odour and anæsthetic influence (Robin, *C. R.* 32, 649). V. sl. sol. water, miscible with alcohol and ether. Burns with difficulty, forming a smokeless green flame. Not acted upon by  $\text{HNO}_3$ , by  $\text{H}_2\text{SO}_4$ , or by potassium.

**Reactions.**—1. When passed through a red-hot tube ethylene and HBr are among the products.—2. Ammonia gives ethylamines. Other bases act similarly.—3. *Alcoholic potash* forms KBr and ether (Berthelot, *A.* 92, 351).—4. *Bromine* forms  $\text{CH}_3\text{CHBr}$ ,  $\text{CH}_3\text{Br}.\text{CH}_2\text{Br}$ , and  $\text{CH}_3\text{Br}.\text{CHBr}$  (114°) (Tavildaroff, *A.* 176, 12).—5. The dry copper-zinc couple forms  $\text{BrZnEt}$ , the combination being facilitated by the presence of a little  $\text{EtH}$ . In presence of water or alcohol ethane is given off on warming (Gladstone & Tribe, *C. J.* 27, 410).—6. A mixture of  $\text{EtB}$  passed over  $\text{AlBr}_3$ , or the compound  $\text{AlBr}_3.\text{C}_2\text{H}_5$  at 60° gives saturated hydrocarbons (Gustavson).

Compound  $\text{EtBr} \cdot \text{S} \cdot 23\text{aq}$  (Forerand, *A. Ch.* (5) 28, 29).

**ETHYL-BROMO-ACETO-ACETIC ETHER** *v.* BROMO-ACETO-ACETIC ETHER.

**ETHYL-DI-BROMO-DI-ALLYL-AMINE**  $\text{C}_6\text{H}_9\text{Br}_2\text{N}$  *i.e.*  $\text{EtN}(\text{C}_2\text{H}_5\text{Br})_2$ . From dibromo-allyl-amine and  $\text{EtI}$  at  $100^\circ$  (Maxwell Simpson, *P. M.* (4) 16, 257). Pungent bitter oil, alkaline to test papers. Precipitates  $\text{Cu}(\text{OH})_2$  from cupric salts.

**ETHYL BROMO-ALLYL OXIDE**  $\text{C}_4\text{H}_7\text{BrO}$  *i.e.*  $\text{EtOCH}_2\text{CHBrCH}_2$  (133°). S.G.  $^{12}$  1.26. From  $\text{EtOCH}_2\text{CHBrCH}_2\text{Br}$  and  $\text{NaOH}$  (Henry, *B.* 5, 188).

Ethyl di-bromo-allyl oxide  $\text{EtOCH}_2\text{CHBrCH}_2\text{Br}$ . From ethyl propargyl oxide and  $\text{Br}$  (Liebermann & Kretschmer, *A.* 158, 284).

**ETHYL-BROMO-AMINE** *v.* ETHYLAMINE.

**ETHYL-BROMO-ANILINE** *v.* BROMO-ETHYL-ANILINE.

**ETHYL BROMO-PENTENYL OXIDE**  $\text{C}_8\text{H}_{13}\text{BrO}$  (179°). S.G.  $^{25}$  1.23. From bromo-amylen bromide (tri-bromo-pentane) and alcoholic  $\text{KOH}$  (Reboul, *A.* 133, 84).

**ETHYL-BROMO-PODOCARPIC ACID** *v.* PODOCARPIC ACID.

**ETHYL ISOBUTYL CARBONATE**  $\text{C}_7\text{H}_{14}\text{O}_2$  *i.e.*  $\text{Et}(\text{C}_4\text{H}_9)\text{CO}_2$  (160-1° cor.). S.G.  $^{22}$  .92 (Röse, *A.* 205, 230).

**ETHYL-ISOBUTYL-GLYOXALINE**  $\text{C}_8\text{H}_{15}\text{N}$  *i.e.*  $\text{C}_4\text{H}_9\text{Et}(\text{C}_2\text{H}_5)\text{N}_2$ . *Oxaethylisoamyline*. (225°). S.G.  $^{19.5}$  .9291. The hydrobromide is formed from isobutyl-glyoxaline (glyoxal-isoamyline) and  $\text{EtBr}$  (Radziszewsky & Szul, *B.* 17, 1294). Oil. —  $\text{B}^1\text{H}_2\text{PtCl}_4$ : orange prisms.

**ETHYL ISOBUTYL KETONE**  $\text{C}_7\text{H}_{14}\text{O}$  (135°) at 735 mm. S.G.  $^{20}$  .820;  $^{18}$  .815. Formed when  $\text{CO}$  is passed over a mixture of sodium isovalerate and  $\text{NaOEt}$  at  $160^\circ$  (Loos, *A.* 202, 327). Also from isovaleryl chloride and  $\text{ZnEt}_2$  (Wagner, *B.* (2) 38, 264; *J. R.* 16, 673). Gives on oxidation acetic and isovaleric acids.

Ethyl *tert*-butyl ketone  $\text{EtCO.CMe}_3$  (126°). S.G.  $^{20}$  .831;  $^{12}$  .810. From  $\text{CMe}_3\text{COCl}$  and  $\text{ZnEt}_2$  (Wyschnegradsky, *A.* 178, 104). Liquid smelling of mint and camphor. Oxidised by  $\text{CrO}_3$  to  $\text{CMe}_3\text{CO}_2\text{H}$ .

**ETHYL-BUTYL-OXIDE**  $\text{C}_7\text{H}_{14}\text{O}$  *i.e.*  $\text{EtO.C}_4\text{H}_9$  (91.4°). S.G.  $^{20}$  .768. S.V. 150.1. C.E. (0°-10°) .00116 (Dobriner, *A.* 243, 5; *cf.* Lieben & Rossi, *A.* 158, 167).

Ethyl isobutyl oxide  $\text{EtOCH}_2\text{Pr}$  (79°). S.G. .75. From  $\text{EtI}$  and  $\text{KOC}_4\text{H}_9$  (Wurtz, *A. Ch.* (3) 42, 129; *A.* 93, 117) or from  $\text{C}_4\text{H}_9\text{Br}$  and  $\text{KOEt}$  (Meissler, *C. C.* 1887, 479).

Ethyl *tert*-butyl oxide  $\text{EtOCMe}_3$  (69°). Formed by heating *tert*-butyl bromide (2 vols.) with  $\text{NEt}_3$  (5 vols.) and alcohol (5 vols.) at  $100^\circ$  (Reboul, *J.* 1881, 409).

**ETHYL ISOBUTYL SULPHATE?**

$\text{Et}(\text{C}_4\text{H}_9)\text{SO}_3$ . From  $\text{C}_4\text{H}_9\text{O.SO}_3\text{Cl}$  and alcohol (Behrend, *J. pr.* (2) 15, 34). Decomposed by water into alcohol and  $\text{H}(\text{C}_4\text{H}_9)\text{SO}_3$ .

**ETHYL ISOBUTYL (α)-THIOCARBONATE**  $\text{EtO.CO.SO}_2\text{C}_4\text{H}_9$  (192°). S.G.  $^{12}$  .994. From  $\text{ClCO.Et}$  and  $\text{NaSC}_4\text{H}_9$  (Mylius, *B.* 6, 813).

Ethyl-isobutyl (α)-di-thio-carbonate  $\text{EtS.CO.OCC}_4\text{H}_9$  (198°). S.G.  $^{12}$  .994. From

$\text{ClCO}_2\text{C}_4\text{H}_9$  and  $\text{NaSEt}$  (M.); *v.* ETHYL THIO-CARBONATES.

Ethyl-isobutyl dithiocarbonate  $\text{C}_4\text{H}_9\text{O.CSSEt}$  (228°). From  $\text{C}_4\text{H}_9\text{O.CSSEt}$  and  $\text{EtI}$  at  $100^\circ$  (Mylius, *B.* 5, 972). Yellow liquid with unpleasant odour, with a taste like aniseed.

**ETHYL CAMPHENE**  $\text{C}_{10}\text{H}_{18}(\text{C}_2\text{H}_5)$ . (198°-200° cor.) at 742 mm. S.G.  $^{22}$  .9709. V.D. = 5.55 (found). Prepared by the action of sodium on a mixture of solid camphor-dichloride [155°] and ethyl iodide (Spitzer, *B.* 11, 1817). Mobile fluid of turpentine-like smell.

**ETHYL-CAMPHOR** *v.* CAMPHOR.

**ETHYL CARBAMATE** *v.* vol. i. p. 679.

**ETHYL - CARBAMIC ACID**  $\text{NHEt.CO}_2\text{H}$ . Ethyl-ammonium salt  $\text{NH}_4\text{EtA}^+$ . From ethylamine and  $\text{CO}_2$  at  $-18^\circ$ . Snow-white powder. Decomposed by water although, like ammonium carbamate, it does not immediately ppt.  $\text{BaCl}_2$  in the cold (Wurtz, *A. Ch.* (3) 80, 448).

*Ethyl ether*  $\text{NEtH.CO}_2\text{Et}$ . (176°). V.D. 4.07. S.G.  $^{21}$  .986. From  $\text{ClCO.Et}$  and  $\text{NEt}_3$  (Schreiner, *J. pr.* (2) 21, 125; 22, 353). Formed also by heating cyanic ether with alcohol in sealed tubes at  $100^\circ$  (Wurtz, *C. R.* 37, 182). Oil. Decomposed by potash into ethylamine, alcohol, and  $\text{K}_2\text{CO}_3$ .

Di-ethyl-carbamic chloride  $\text{Cl.CO.NEt}_2$ . *Chloro-formic acid diethylamide*. (190°-195°). Prepared by the action of  $\text{PCl}_5$  on diethyl-oxamic acid,  $\text{CO}$  being evolved (Wallach, *B.* 14, 746). Liquid. By treatment with diethylamine it gives tetra-ethyl-urea. By water it is decomposed into  $\text{CO}_2$  and diethylamine hydrochloride.

**ETHYL CARBAMINE**  $\text{CNC}_2\text{H}_5$ . (78°). Mol. w. 55. From ethyl iodide and silver cyanide (*v.* vol. i. p. 680). Also from  $\text{EtI}$  and mercuric fulminate (Calmels, *J. pr.* (2) 30, 319). Stinking liquid. Does not solidify at  $-68^\circ$ . Split up by acids into formic acid and ethylamine.  $\text{HgO}$  added to a solution of ethyl carbamine (1 vol.) in ether (4 vols.) forms  $\text{C}_2\text{H}_5\text{N}_2\text{O}_2$  [122°].  $\text{Br}$  forms oily  $\text{NC}_2\text{H}_5\text{Br}_2$  (Tscherniak, *B.* (2) 30, 105).

Ethyl-carbamine cyamide *v.* CARBIMIDO-ETHYL-UREA.

**DI-ETHYL SEMI-CARBAZIDE**  $\text{C}_4\text{H}_8\text{N}_2\text{O}$  *i.e.*  $\text{NH}_2\text{CO.NH}_2\text{Et}$ . [106°]. From ethyl-hydrazine hydrochloride and conc. aqueous potassium cyanate (Fischer, *A.* 199, 284). Laminæ; *v. e.* sol. water and alcohol, sl. sol. ether and conc. alkalis. Reduces Fehling's solution and  $\text{HgO}$  only when warm.

s-Di-ethyl-semicarbazide  $\text{C}_4\text{H}_8\text{N}_2\text{O}$  *i.e.*  $\text{NHEt.CO.NEt.NH}_2$ . From the nitrosamine of s-di-ethyl-urea  $\text{NHEt.CO.NEt.NO}$  by reduction with zinc-dust and  $\text{HOAc}$  in alcoholic solution (Fischer, *A.* 199, 284). Crystallises with difficulty; *v. sol.* water and alcohol. Reduces Fehling's solution only when warm. Boiling conc.  $\text{HClAq}$  splits it up into  $\text{CO}_2$ , ethyl-hydrazine, and  $\text{NH}_4\text{Et}$ . —  $\text{B}^1\text{HCl}$ : slender needles. —  $\text{B}^1\text{H}_2\text{PtCl}_4$ .

α-Di-ethyl-semicarbazide  $\text{NH}_2\text{CO.NH.NEt}$ . [149°]. Formed by the action of potassium cyanate on the neutral salts of α-di-ethyl-hydrazine (F.). Long slender prisms (from alcohol); *v. e.* sol. alcohol and hot water, *v. sl. sol.* ether. Reduces boiling Fehling's solution with much difficulty. —  $\text{B}^1\text{H}_2\text{PtCl}_4$ : slender yellow needles (from alcohol).

**Nitrosamine**  $\text{NH}_2\text{CO.N(NO).NEt}_2$ . Yellow plates; al. sol. water, v. sol. alcohol and ether. Dilute KOH splits it up at once into diethylamine,  $\text{CO}_2$ , ammonia, and  $\text{N}_2\text{O}$ .

**ETHYL-CARBAZOLE**  $\text{C}_{11}\text{H}_{13}\text{N}$  i.e.

$\langle \text{C}_6\text{H}_4 \rangle_{\text{C}_2\text{H}_5}\text{NEt}_2$ . [67°]. From potassium carbazole and EtI (Graebe, A. 202, 23). Leaflets, sol. ether and hot alcohol. insol. water. Its picrate  $\text{C}_6\text{H}_5\text{NC}_2\text{H}_5(\text{NO}_2)_2\text{OH}$  crystallises in needles [97°].

**ETHYL-CARBAZOLINE**  $\text{C}_{11}\text{H}_{13}\text{N}$  i.e.

$\text{C}_{11}\text{H}_{13}\text{NEt}_2$ . Hydroiodide  $\text{BHI}$ . From carbazole, EtI, and alcohol at 100° (Graebe a. Behaghel, A. 202, 25). Thick tables, v. sol. hot water.

**ETHYL - CARBIMIDO - METHYL - THIO -**

**UREA**  $\text{SC} \langle \text{NH} \rangle \text{C:NEt}$  or  $\text{MeNH.CS.N:C:NEt}$ .

*Methyl-thio-carbamine-ethyl-cyamide*. [106°]. Formed by the action of ethyl iodide upon sodium carbimido-methyl-thiourea (Wunderlich, B. 19, 448).

**ETHYL-CARBIMIDO-PHENYL-THIO-UREA**

$\text{SC} \langle \text{NPh} \rangle \text{C:NEt}$  or  $\text{PhNH.CS.N:C:NEt}$ . *Phenyl-thio-carbamine-ethyl-cyamide*. [119°]. Formed by the action of ethyl-iodide upon sodium carbimido-phenyl-thio-urea. Crystalline solid. V. sol. water and alcohol. Indifferent body (Wunderlich, B. 19, 448).

**ETHYL-CARBIMIDO-UREA**

$\text{OC} \langle \text{NH} \rangle \text{C:NEt}$  or  $\text{H}_2\text{N.CO.N:C:NEt}$ . *Carbamine-ethyl-cyamide*. [121°]. Formed by the action of ethyl iodide upon sodium carbimido-urea ('amido-dicyan acid'). Neutral body (Wunderlich, B. 19, 448).

**DI-ETHYL-CARBINOL** v. AMYL ALCOHOL.

**Tri-ethyl-carbinol** v. HEPTYL ALCOHOL.

**DI-ETHYL-CARBINYL** v. AMYL.

**DI-ETHYL-CARBOBENZOIC ACID**  $\text{C}_{14}\text{H}_{16}\text{O}_2$  or  $\text{C}_{14}\text{H}_{14}\text{O}_2$ ? [102°]. (239°) at 11 mm. An acid formed when deoxybenzoin is heated with alcoholic KOH (Limpricht a. Schwanert, A. 155, 66; Zagoumenny, A. 184, 163; Anschütz a. Berns, B. 20, 1892). Slender needles (from ether). Converted by potash-fusion into benzoic and di-ethyl-benzoic acids. Dilute  $\text{H}_2\text{SO}_4$  forms crystalline  $\text{C}_{14}\text{H}_{14}\text{O}_2$  [132°] and other bodies.  $\text{HNO}_3$  gives a di-nitro-derivative [156°].

**Salts.**— $\text{AgA}$ : amorphous.— $\text{EtA}$ : oil.

**ETHYL CARBONATE**  $\text{C}_4\text{H}_8\text{O}_3$  i.e.  $\text{Et}_2\text{CO}_3$ . Mol. w. 118½. (126° cor.) (Kopp, A. 95, 325). S.G. 2-9762.  $\mu_D = 1.3897$ .  $n_D = 1.4541$  (Brühl, A. 208, 23). H.F.p. 152,500. H.F.v. 149,310 (Th. 4, 218). H.C. 641,448 (Lougumine, Bl. [2] 41, 389). V.D. 4-09 (obs. and calc. Cahours).

**Formation.**—1. By the action of potassium or sodium on oxalic ether at 130°, the metal being added as long as  $\text{CO}$  escapes; water is then added, and the  $\text{Et}_2\text{CO}_3$  dried over  $\text{CaCl}_2$  and rectified (Etling, A. 19, 17).—2. By distilling a mixture of  $\text{KEtCO}_3$  with  $\text{KEtSO}_3$  (Chancel, C. R. 31, 521).—3. By the action of  $\text{NaOEt}$  on oxalic ether (Cranston a. Dittmar, C. J. 22, 441).—4. From  $\text{ClCO}_2\text{Et}$  and  $\text{NaOEt}$  (Schreiner, J. pr. [2] 22, 858).

**Properties.**—Colourless liquid, burning with blue flame. Insol. water, v. sol. alcohol and ether. Chlorine gives products of substitution

(Cahours, A. Ch. [3] 9, 201). Saturated with  $\text{HBr}$  and heated to 100° there are formed  $\text{EtBr}$ ,  $\text{CO}_2$ , and water (Gal, C. R. 59, 1049). By heating with sodium or  $\text{NaOEt}$  in sealed tubes it yields  $\text{NaEtCO}_3$ , carbonic oxide, and  $\text{Et}_2\text{O}$  (Geuther, Z. [2] 4, 656). Ammonia at 100° forms carbamic ether; at 180° ammonia gives urea (Natanson, A. 98, 287).  $\text{PCl}_5$  gives  $\text{EtCl}$  and  $\text{ClCO}_2\text{Et}$  (Geuther, A. 205, 247).

**Potassium ethyl carbonate**  $\text{KEtCO}_3$ . When  $\text{CO}_2$  is passed into a solution of KOH in absolute alcohol there is formed a crystalline deposit consisting of  $\text{KEtCO}_3$ ,  $\text{KHCO}_3$ , and  $\text{K}_2\text{CO}_3$ ; the mass is washed with ether, the  $\text{KEtCO}_3$  is then dissolved in alcohol and ppd. by ether (Dumas a. Peligot, A. Ch. [2] 74, 6). White nacreous salt; split up by water into alcohol and  $\text{KHCO}_3$ .  $\text{NaEtCO}_3$  and amorphous  $\text{Ba(EtCO}_3)_2$  are obtained by passing  $\text{CO}_2$  into alcoholic solutions of  $\text{NaOEt}$  and  $\text{Ba(OEt)}_2$ , respectively (Beilstein, A. 112, 124; Destrem, A. Ch. [5] 27, 10).

**Ethyl ortho-carbonate**  $\text{C(OEt)}_2$ . Mol. w. 192. (159°). V.D. 6-80 (calc. 6-65). Sodium (24 g.) is added in small portions to a boiling solution of chloropirrin (40 g.) in absolute alcohol (300 g.); as soon as the reaction is finished the excess of alcohol is distilled off and water is added to the residue; the oil is then dried by  $\text{CaCl}_2$  and rectified (Bassett, C. J. 17, 198). Oil, with peculiar aromatic odour. Decomposed by boiling alcoholic KOH.  $\text{B}_2\text{O}_3$  at 100° forms borie ether and  $\text{Et}_2\text{CO}$ . Bromine forms  $\text{EtBr}$ ,  $\text{Et}_2\text{CO}$ , bromal, &c. (Ladenburg a. Wichelhaus, A. 152, 166). Ammonia forms guanidine.

**Reference:** TETRA-CHLORO-DI-ETHYLCARBONATE.

**ETHYL-CARBOPYRROL-AMIDE** v. ETHYL-PYRROLE CARBOXYLIC ACID.

**ETHYL-CARBOSTYRIL** v. Ethyl ether of OXY-QUINOLINE and OXY-ETHYL-QUINOLINE.

**ETHYL CARBYLAMINE** v. ETHYL-CARB-AMINE.

**ETHYL CETYL OXIDE**  $(\text{C}_2\text{H}_5)(\text{C}_{18}\text{H}_{37})\text{O}$ . [20°]. Fine white needles. From cetyl iodide and  $\text{EtONa}$  (Becker, A. 102, 220; Walder, B. 20, 1754).

**ETHYL PERCHLORATE**  $\text{C}_2\text{H}_5\text{ClO}_4$ . Obtained by distilling a mixture of  $\text{Ba(EtSO}_4)_2$  with  $\text{Ba(ClO}_4)_2$  in quantities of 4 g. at a time (to avoid explosion) (Clark, Hare, a. Boyle, P. M. [3] 19, 370; Roscoe, C. J. 15, 213). The distillate separates into two layers, the upper one consisting of water which may be removed by blotting-paper. Colourless heavy oil, with pleasant odour and sweet taste. Explodes on the least provocation with excessive violence. It may be kept under water or in alcoholic solution. It may be distilled under a layer of water, passing over at 74°. It is immediately saponified by alcoholic potash.

**ETHYL CHLORIDE**  $\text{C}_2\text{H}_5\text{Cl}$ . *Chloro-ethane*. Mol. w. 64½. (12-5°) (Regnault, J. 1868, 87). S.G. 2-9280; 2-9171 (Perkin, C. J. 45, 449). V.D. 2-22 (calc. 2-24). H.F.p. (gaseous) 28,000; (liquid) 84,400 (Berthelot); 80,710 (Thomsen, Th.). H.F.v. 28,550 (Th.). M.M. 4-039 at 5° (P.). S.V. 75-8 (Ramsay).

**Formation.**—1. By chlorinating ethane (Schorlemmer, C. R. 58, 708; A. 182, 284).—2. By the action of  $\text{HCl}$  on alcohol alone or in presence of  $\text{ZnCl}_2$  (Robiquet a. Colin, A. Ch. [2]

**1, 348**; Regnault, *A. Ch.* [2] 71, 355; Kuhlmann, *A.* 33, 108; Löwig, *P.* 45, 346).—8. By the action of  $\text{SOCl}$ ,  $\text{PCl}_5$ ,  $\text{Al}_2\text{Cl}_6$ ,  $\text{SbCl}_5$ ,  $\text{Fe}_2\text{Cl}_6$ ,  $\text{SnCl}_4$ , &c., on alcohol.—4. From  $\text{EtI}$  and chlorine.—5. By treating acetic and other ethers with  $\text{HCl}$ .

**Preparation.**—1. HCl is passed into a boiling solution of  $\text{ZnCl}_2$  (2 pts.) in 95 p.c. alcohol (3 pts.) in a flask with inverted condenser. The escaping gas is washed with water. The yield is nearly the theoretical (Groves, *C.J.* 27, 637).—2. By distilling a mixture of alcohol (5 pts.),  $\text{H}_2\text{SO}_4$  (2 pts.), and NaCl (12 pts.).

*Properties.*—Gas, burning with green-edged flame. V. sl. sol. water, v. e. sol. alcohol and ether. Gives no pp. with silver nitrate solution in the cold.

**Reactions.**—1. Aqueous HI (S.G. 1.9) at 130° converts it into EtI.—2. SO, forms  $\text{ClSO}_2\text{OEt}$  (R. Williamson, *C. J.* 10, 100). By-products are also formed (Von Purgold, *B.* 6, 502).—3. Aqueous  $\text{AgNO}_3$  at 100° gives a pp. of  $\text{AgCl}$  (G. C. Foster).—4. Boiling aqueous KOH slowly forms alcohol; alcoholic potash acts more readily, forming KCl, alcohol, and ether (Balard, *A. Ch.* [3] 12, 302).—5. *Ammonia* forms ethylamines (Groves, *O. J.* 13, 331). Equal volumes of  $\text{C}_2\text{H}_5\text{Cl}$  and  $\text{NH}_3$  gas submitted to a pressure of 70 atmospheres for 48 hours at 175° do not react. The introduction of a small quantity of alcohol does not affect the result. In the cold an alcoholic solution of  $\text{NH}_3$  and  $\text{C}_2\text{H}_5\text{Cl}$  requires to be kept several days before any action commences, and the reaction is not complete after several months (Vincent & Chappuis, *Bl.* [2] 45, 503).—6. Alcoholic  $\text{K}_2\text{S}$  and KHS give  $\text{Et}_2\text{S}$  and mercaptan respectively (Regnault).—7. Passed over red-hot lime it forms acetic acid,  $\text{CH}_3\text{I}$ , and hydrogen (L. Meyer, *A.* 139, 282; cf. Dumas & Stas, *A. Ch.* [2] 73, 154).

**Derivatives.**—CHLORO-ETHANES and CHLORO-BROMO-ETHANES, ETHYLENE CHLORIDE and ETHYLIDENE CHLORIDE.

ETHYL-CHLORO-ACETO-ACETIC ETHER.  
2. CHLORO-ACETO-ACETIC ETHER.

**ETHYL CHLORO-ACETYLENE CARBOXY-  
LIC ACID v. CHLORO-BUTANE CARBOXYLIC ACID.**

**ETHYL-DI-CHLORO-DI-ALLYL-AMINE**  
 $\text{Net}(\text{C}_2\text{H}_4\text{Cl})_2$ . (c. 200). From  $\text{NH}(\text{C}_2\text{H}_4\text{Cl})_2$  and EtI at  $100^\circ$  (Engler, *Bt.* [2] 9, 184; *A.* 142, 81).  
 Oil.— $\text{B}^2\text{H}_2\text{PtCl}_4$ : crystalline.

**Di-ethyl-chloro-allyl-amine.** *Ethylchloride*  $C_2H_5Cl$ ,  $Cl$ ,  $NET$ ,  $Cl$ . Two compounds of this constitution are formed by heating *s*-tri-chloro-ethane  $C_2H_3Cl_3$ ,  $CHCl$ ,  $CHCl$ ,  $CHCl$  with  $NET$ , (Reboul, *C. R.* 95, 993). They differ in the solubility of their Pt salts. Two di-chloro-propylenes appear to be intermediate in the formation of these ethyl-chlorides.

**ETHYL  $\alpha$ -CHLORO-ALLYL OXIDE**  $C_4H_7ClO$   
i.e.  $Et.O.CH_2.CCl.CH_2$ . (110°). S.G. 2 1.011;  
21.5-995. From  $CH_2.CCl.CH_2.Cl$  and alcoholic  
KOH (Friedel & Silva, *J.* 1872, 823). Formed  
also from ethyl allyl oxide by successive treat-  
ment with  $Cl$  and KOH (Henry, *B.* 5, 189).

**Ethyl 3-chloro-allyl oxide**  
Et.O.CH<sub>2</sub>.CH:CHCl. (120°-125°). S.G. 2:1.021;  $n_D^{20}$  1.4994. From CH<sub>2</sub>Cl.CH:CHCl and alcoholic KOH (F. & S.). Br forms EtO.CH<sub>2</sub>.CHBr.CHClBr (220°).

**ETHYL-CHLORO-AMINE v. ETHYLAMINE.**

**DI-ETHYL CHLORO-AMYL PHOSPHATE**  
 $\text{Et}_2(\text{C}_5\text{H}_9\text{CHCl})\text{PO}_2$ . From  $\text{C}_5\text{H}_9\text{CH}_2\text{PO}(\text{OH})_2$  by successive treatment with  $\text{PCl}_5$  and alcohol (Fossek, *M.* 7, 20).

**ETHYL-CHLORO-ANILINE** v. **CHLORO-ETHYL-ANILINE.**

**TRI-ETHYL-CHLORO-AUROPHOSPHITE**  
 $\text{Et}_3\text{P}(\text{AuClO})$ , [c.  $-10^\circ$ ]. S.G. 2.025. Obtained by adding absolute alcohol to a mixture of  $\text{AuCl}$  and dry phosphorus and ppg. by water (Lindet, *C. R.* 103, 1014). Crystalline mass; decomposes about  $100^\circ$ . Insol. water, mol. alcohol, ether, and benzene. NH. forms  $\text{Et}_3\text{P}(\text{AuClO})\cdot\text{NH}_3$ .

**ETHYL-CHLORO-BENZENE** v. **CHLORO-ETHYL-BENZENE.**

**ETHYL-CHLORO-BROMO-PROPYL OXIDE**  
 $\text{Et.CO.C}_2\text{H}_4\text{ClBr}$ . (187°). From epichlorhydrin  
 and  $\text{EtBr}$  at 200° (Reboul & Lourenço, A. 119  
 238).

**ETHYL CHLORO-BUTENYL OXIDE**  
 $C_4H_7ClOEt$ . (134°). From  $CH_3CH:CH.CHCl_2$   
 and alcoholic KOH (Kekulé, *A.* 162, 98).

**ETHYL CHLORO-BUTYL OXIDE**  
 $\text{CH}_3\text{CH}_2\text{OCH}_2\text{CH}_2\text{CH}_2\text{CH}_3$ . (141°). S.G.  $d_{20}^{20}$  0.974. V.D. 69.3 (calc. 68.3). From  $\text{ZnEt}_2$  and an ethereal solution of di-chloro-di-ethyl oxide (Lieben, A. 123, 130; 133, 287; 146, 220). Oil, miscible with alcohol and ether.

**Reactions.**—1. HI gives EtI and secondary butyl iodide.—2. With NaOEt it gives butylene glycol diethyl ether:  $\text{CH}_3(\text{OEt})\text{CHEt}.\text{OEt}$ , (147°).—3. PBr<sub>3</sub> gives  $\text{CH}_3\text{Cl}.\text{CHEtBr}$ , ethyl bromide, and  $\text{CH}_3\text{Br}.\text{CHEtBr}$ .

ETHYL-CHLORO-ETHANE TETRA-CAR-  
BOXYLIC ACID v. CHLORO-BUTANE TETRA-CAR-  
BOXYLIC ACID.

ETHYL-CHLORO-MALONIC ETHER v.  
CHLORO-ETHYL-MALONIC ETHER.

ETHYL-DI-CHLORO-PHOSPHINE o. ETHYL-PHOSPHINE.

**ETHYL CHLORO-ISOPROPYL OXIDE**  
CH<sub>3</sub>CH<sub>2</sub>CH<sub>2</sub>Me.OEt. (118°). S.G. 2.984. From

ZnMe<sub>2</sub> and dichloro-diethyl ether (Lieben, A. 146, 225). PBr<sub>3</sub> gives MeBr, CH<sub>2</sub>Cl.CHMeBr, and OH.Br.CHMeBr.

ETHYL-CHLORO-QUINOLINE v. CHLORO-ETHYL-QUINOLINE.

**ETHYL-CHLORO-SULPHATE v. ETHYL SULPHATE.**

**ETHYL-CINCHONIDINE v. CINCHONIDINE.**

### ETHYL-CINCHONINE v. CINCHONINE.

**ETHYL-CITRIC ACID v. CITRIC ACID.**

**ETHYL-CODEINE v. CODEINE.**

**ETHYL-CONHYDRINE v. CONIINE.**

ETHYL-CONIINE v. CONIINE.  
ETHYL-COUMAZONIC ACID  $C_{11}H_{11}NO$ .

$$\text{d.s. } \text{C}_6\text{H}_5(\text{CO}_2\text{H}) \begin{matrix} \text{OMe}_2\text{O} \\ \bullet \\ \text{N} - \text{OEt} \end{matrix} (?). \quad [202^\circ]. \quad \text{Small}$$

glistening pyramids. V. sol. alcohol, insol. water. Formed by boiling (8:4:1)-amido-oxypropylbenzoic acid with propionic anhydride.  
Salts.— $\text{A}^+\text{HCl}$ : very soluble white needles.— $\text{A}^+\text{H}_2\text{SO}_4$ : very soluble white needles (Widmann, B. 16, 2576).

(Widmann, B. 16, 2576).

**ETHYL CRESYL ETHER** *v.* *Ethyl derivative of Cresol.*

**ETHYL-CROTONIC ACID** *v.* *Hexenoic acid.*

**ETHYL ISOCROTYL ETHER** *v.* *Ethyl ether of Butenyl alcohol*, vol. i. p. 639.

**ETHYL-CUMENE** *v.* **ETHYL-PROPYL-BENZENE.**

**ETHYL-CUMIDINE**  $C_8H_9N$  *i.e.*  $C_8H_7Me_2NHet$ . (220°-230°). Formed by heating cumidine hydrochloride (1 mol.) with alcohol (1 mol.) for 4 hours at 125° (Ruttan, B. 19, 2383).

**ETHYL CYANAMIDE** *v.* *Cyanamide under Cyanic acid.*

**ETHYL-CYANIC ACID** *v.* *Cyanic acid.*

**ETHYL CYANIDE** *v.* *Propionitrile and Ethyl carbamine.*

**ETHYL-CYANURIC ACID** *v.* *Cyanuric acid under Cyanic acid.*

**ETHYLENE**  $C_2H_4$ , *i.e.*  $CH_2:CH_2$ . Mol. w. 28. [-169°] (Olzowski, M. 8, 71); [-103°] (Cailliet, C.R. 94, 1224; Wroblewski, M. 4, 338). V.D. -9784 (Saussure; calc. -9702). H.F.p. -8,000 (Favre & Silbermann); -9,400 (Berthelot, A. Ch. [5] 23, 180); -4,160 (Thomsen, J. pr. [2] 23, 159); -2,710 (Thomsen, Th.). H.F.v. -3,290 (Th.). Critical temperature, 13°. S. 25 at 0°; S. (alcohol) 8.6 at 0° (Carius, A. 94, 133). Discovered by treating alcohol with  $H_2SO_4$  in 1795 by the four Dutch chemists: Deiman, Pats van Troostwyk, Bondt, and Lauwerenburgh (Crell. Ann. 1795, ii. 195, 310; Glib. Ann. 2, 201). It is a product of the dry distillation of most organic bodies, *e.g.* formates, acetates, butyrates, fats, resins, caoutchouc, wood, and coal. It is the most abundant illuminating constituent in coal gas.

**Formation.**—1. Formed, as well as other hydrocarbons, when a mixture of  $CS_2$  and  $H_2S$  or  $H_2P$  is passed over red-hot copper; or, more abundantly, when a mixture of  $CS_2$ ,  $H_2S$ , and  $CO$  is passed over red-hot iron (Berthelot, C. R. 43, 236).—2. Formed together with  $CH_4$  and butylene by the dry distillation of barium formate.—3. By heating a mixture of alcohol (1 vol.) with conc.  $H_2SO_4$  (4 vols.) (Mitscherlich, A. Ch. [3] 7, 12).—4. By heating alcohol (1 pt.) with fused  $B_2O_3$  (4 pts.) (Ebelmen, A. Ch. [3] 16, 136).—5. By the electrolysis of a concentrated solution of sodium succinate (Kekulé, A. 131, 79).—6. Together with benzene, by heating styrene with hydrogen in sealed tubes (Berthelot, J. 1866, 544).—7. By treating ethylidene chloride with sodium (Tollens, A. 137, 311).—8. From ethyl iodide and zinc (E. Frankland & L. Dobbie, C. J. 35, 645).

**Preparation.**—Alcohol (25 g.) and  $H_2SO_4$  (150 g.) are heated in a flask to 165°, and a mixture of alcohol (1 pt.) and  $H_2SO_4$  (2 pts.) is run in slowly. The gas is washed with  $NaOH$  and  $H_2SO_4$  (Erlenmeyer & Bunte, A. 168, 64; 192, 244).

**Properties.**—Colourless gas with faint ethereal odour (?). V. al. sol. water, al. sol. alcohol, m. sol. ether. Pure ethylene burnt at the rate of 5 cubic feet per hour emits a light equal to 68.5 standard candles; the illuminating power of a given quantity of  $C_2H_4$  is increased by moderate admixture with  $H_2$ ,  $CO$ , or  $CH_4$ , although the actual amount of light given per cubic foot of the mixture is less than that given by pure ethylene. The intrinsic illuminating power is

reduced by admixture with  $N$ ,  $CO_2$ , or water-vapour, but increased by  $O$  (P. F. Frankland, C. J. 45, 30, 227). It unites directly with chlorine, bromine, iodine,  $N_2O$ ,  $S_2Cl_2$ , and  $SO_2$ . It is quickly absorbed by Nordhausen sulphuric acid, forming ethionio acid and its anhydride. Conc.  $H_2SO_4$  absorbs it, forming  $HEtSO_4$ ; the absorption takes place rapidly at 100°-170°, but at ordinary temperature much shaking is required. Ethylene forms with water under pressure a crystalline hydrate (Villard, C. R. 106, 1602).

**Reactions.**—1. When passed through a red-hot tube carbon is deposited and marsh-gas formed. The decomposition commences at as low a temperature as 355°; at this temperature a condensation change only takes place, and is very slow, requiring 20 hours or more for its completion. Heated to 400° for a sufficient length of time it is entirely decomposed with formation of marsh-gas, ethane, and liquid products (Day, Am. 8, 153). According to Berthelot (Bl. [2] 9, 456) these liquid products contain benzene and styrene. Norton & Noyes (Am. 8, 362) found benzene, naphthalene, and anthracene, as well as methylene, propylene, butylene, and crotonylene,  $CH_3:CH:CH_2$ , with  $CH_4$  and  $C_2H_6$ . When heated in a glass tube to dull redness with an equal volume of acetylene it appears to form butylene (Berthelot, J. 1866, 519). When a mixture of ethylene and hydrogen is passed over platinum, even in the cold, ethane is formed (Von Wilde, B. 7, 352). A mixture of ethylene and diphenyl passed through a red-hot porcelain tube forms phenanthrene, anthracene, benzene, styrene, and naphthalene (Barbier, C. R. 79, 121).—2. With oxygen (3 vols.) it forms a highly explosive mixture. When a mixture of ethylene and air is passed over red-hot platinum wire some acetic acid is formed (Coquillion, C. R. 77, 444). When ethylene is oxidised by weakly ozonised oxygen, formic acid and  $CO_2$  result (Houzeau & Renard, C. R. 76, 572).—3. It burns in chlorine with a smoky flame:

In the dark and in the cold it unites with chlorine, forming oily 'Dutch liquid'  $C_2H_4Cl_2$ .

4.  $HI$  at 100° forms  $EtI$  (Berthelot, A. 104, 184; 115, 114; J. 1867, 344).  $HBr$  also unites with ethylene, but  $HCl$  does not.—5. Dry  $ICl$  forms  $C_2H_4Cl_2$  and iodine (Geuther, J. 1862, 421; Thorpe, C. J. 37, 179).—6. Chromic acid solution oxidises it to  $CO_2$  (Ludwig, A. 162, 47). Chromic acid mixture forms chiefly oxalic and acetic acids (Zeidler, A. 197, 213; Berthelot (C. R. 68, 334) found even aldehyde).—7. Potassium permanganate solution containing  $H_2SO_4$  is decolourised by ethylene,  $CO_2$ , and formic and acetic acids being formed. Neutral and alkaline  $KMnO_4$  forms chiefly oxalic acid and  $CO_2$ , together with a little formic acid (Zeidler; Truchot, C. R. 68, 274; Berthelot, C. R. 64, 56). Neutral  $KMnO_4$  solution forms also glycol (Wagner, B. 21, 1230).—8.—Fuming  $HNO_3$  absorbs it, forming oxalic acid.—9.  $ClSO_3H$  absorbs dry ethylene with rise of temperature; at 90° isethionio anhydride  $C_2H_4SO_3$  is formed, but if the sulphuric chlorhydrin be kept cool and the product poured into water an oil,  $C_2H_4SO_3Cl$  (154°), smelling like mustard oil, is obtained; this oil is converted by water at 100° into isethionio acid, and by

dry NH<sub>3</sub> into deliquescent tables of C<sub>2</sub>H<sub>4</sub>NSO<sub>3</sub> (Baumstark, Z. 1867, 566).—10. *Boron fluoride* at 80° in sunlight forms C<sub>2</sub>H<sub>4</sub>BF<sub>3</sub>, an ethereal liquid (125°) S.G. 2<sup>a</sup> 1.0478, V.D. 2.55, which fumes in the air. It is decomposed by water into ethylene, H<sub>2</sub>BO<sub>3</sub>, and HF (Landolph, C. R. 86, 671, 1267; 89, 173). This 'fluoboro-ethylene' acting upon camphor at 200° forms a hydrocarbon C<sub>12</sub>H<sub>18</sub>.—11. Ethylene and HBr passed over AlBr<sub>3</sub> form AlBr<sub>3</sub>C<sub>2</sub>H<sub>5</sub>, and ethyl bromide. C<sub>2</sub>H<sub>4</sub>, HCl, and AlCl<sub>3</sub> give AlCl<sub>3</sub>C<sub>2</sub>H<sub>5</sub> (Gustavson, J. pr. [2] 34, 161). At the same time saturated hydrocarbons are formed—very little at 0°, much at 70°; they are formed by the simultaneous action of C<sub>2</sub>H<sub>4</sub> and HBr on AlBr<sub>3</sub>C<sub>2</sub>H<sub>5</sub>. Ethyl bromide at 60° acts like C<sub>2</sub>H<sub>5</sub>, mixed with HBr. AlBr<sub>3</sub>C<sub>2</sub>H<sub>5</sub> gives saturated hydrocarbons, not only with C<sub>2</sub>H<sub>4</sub> and HBr, but also with EtBr, PrBr, isobutyl bromide, and MeBr. In all these cases the AlBr<sub>3</sub>C<sub>2</sub>H<sub>5</sub> becomes richer in carbon.—12. *Chloride of sulphur* forms S<sub>2</sub>(CH<sub>2</sub>CH<sub>2</sub>Cl)<sub>2</sub> (Guthrie, A. 119, 91; 121, 108; Spring a. Leerenier, Bl. [2] 48, 629).—13. Cl<sub>2</sub>O forms chiefly CH<sub>2</sub>Cl.CO.O.CH<sub>2</sub>CH<sub>2</sub>Cl (chloro-ethyl chloro-acetate (Mulder a. Bremer, B. 11, 1958).—14. HClO forms CH<sub>2</sub>Cl.CH<sub>2</sub>OH (Carius, A. 126, 197).—15. A solution of PtCl<sub>2</sub> in conc. HCl aq forms C<sub>2</sub>H<sub>4</sub>PtCl<sub>2</sub> (Birnbau, A. 145, 69). The same compound is formed by boiling PtCl<sub>2</sub> with alcohol (Zeise, P. 21, 497, 542; 40, 234; Griess a. Martius, Pr. 11, 509). It is a yellow mass, sl. sol. water; decomposed by light. In aqueous solution it is unstable unless HCl is present. KOH ppts. on warming an explosive powder. It forms the following combinations: NH<sub>3</sub>C<sub>2</sub>H<sub>4</sub>PtCl<sub>2</sub>; yellow pp.—NH<sub>3</sub>ClC<sub>2</sub>H<sub>4</sub>PtCl<sub>2</sub> aq: lemon-yellow prisms.—KClC<sub>2</sub>H<sub>4</sub>PtCl<sub>2</sub> aq.—KBrC<sub>2</sub>H<sub>4</sub>PtBr<sub>2</sub> aq: pale-yellow needles (Chojnacki, Z. 1870, 421).—C<sub>2</sub>H<sub>4</sub>PtCl<sub>2</sub>(Et<sub>2</sub>PO<sub>3</sub>)<sub>2</sub> (Schützenberger, Bl. [2] 18, 103). The corresponding Ni<sub>2</sub>Cl<sub>2</sub>C<sub>2</sub>H<sub>4</sub>IrCl<sub>2</sub> and (KClC<sub>2</sub>H<sub>4</sub>)<sub>2</sub>IrCl<sub>2</sub> may also be prepared (Sadler, Bl. [2] 17, 54).—16. When ethylene is passed into conc. aqueous FeBr<sub>3</sub> in sunlight there are formed greenish deliquescent crystals of C<sub>2</sub>H<sub>4</sub>FeBr<sub>2</sub>2aq (Chojnacki). The corresponding C<sub>2</sub>H<sub>4</sub>FeCl<sub>2</sub>2aq is got by heating ether (50 g.) with Fe<sub>2</sub>Cl<sub>3</sub> (5 g.), P (½ g.) and CS<sub>2</sub> (2 g.) at 100° (Kachler, B. 2, 510).

*Derivatives of ethylene: v. BROMO-, BROMO-NITRO-, BROMO-IODO-, CHLORO-, CHLORO-NITRO-, CHLORO-IODO- &c. ETHYLENE.*

**ETHYLENE-ACETOACETIC ACID v. ACETOACETIC ACID.**

**ETHYLENE ALCOHOL v. GLYCOL.**

**ETHYLENE-ORTHALDEHYDE v. ALDEHYDE.**

**ETHYLENE-DI-ALLYL-DI-THIO-DI-UREA** C<sub>2</sub>H<sub>4</sub>(NH.CS.NHC.H<sub>3</sub>)<sub>2</sub>. From ethylene-diamine and allyl thiocarbimide (mustard oil) in alcohol. Brownish oil, miscible with chloroform and with alcohol. Has an unpleasant odour (Lellmann a. Würthner, A. 228, 234).

**ETHYLENE-DI-m-AMIDO-DIBENZOIC ACID** C<sub>2</sub>H<sub>4</sub>(NH.C<sub>6</sub>H<sub>3</sub>.CO<sub>2</sub>H)<sub>2</sub> [272°-225°]. From ethylene bromide and m-amido-benzoic acid by boiling 24 hours in alcoholic solution (Schiff a. Parenti, A. 226, 244). Hardly sol. water, sol. boiling alcohol. Insol. dilute HCl, sol. aqueous NaOH. With KOH (4 mols.) and EtI (6 mols.) it forms needles of C<sub>2</sub>H<sub>4</sub>N<sub>2</sub>O<sub>2</sub> (100°).

**Salt.**—CuA<sup>2</sup>aq.

**ETHYLENE-DI-β-AMIDO-DI-(α)-CROTONIC ACID** C<sub>2</sub>H<sub>4</sub>(NH.CMe:CH.CO.OH)<sub>2</sub>. [188°]. Obtained by saponification of the ether or by heating ethylene diamine with three times its weight of acetoacetic ether for an hour at 140°. White silky scales. V. sol. water and hot alcohol, sl. sol. ether, benzene, and cold alcohol. Gives a violet colouration with FeCl<sub>3</sub>.

*Di-ethyl ether* A<sup>2</sup>Et<sub>2</sub>: [127°]; obtained by mixing ethylene-diamine and acetoacetic ether in aqueous or alcoholic solution; large white prisms; sol. hot alcohol, ether, and benzene, sl. sol. these solvents when cold, insol. water; conc. HCl decomposes it into acetoacetic ether and ethylene-diamine (Mason, B. 20, 273).

**ETHYLENE-DIAMINE** C<sub>2</sub>H<sub>4</sub>N<sub>2</sub> &c.

NH<sub>2</sub>.CH<sub>2</sub>.CH<sub>2</sub>.NH<sub>2</sub>. Mol. w. 80. [87°]. (117°). V. D. 2.00 (calc. 2.08). S.G. 1<sup>a</sup> 0.902.

*Formation.*—1. From ethylene bromide and alcoholic ammonia in the cold (Hofmann, Pr. 9, 154; 10, 224; cf. Cloez, J. 1853, 468).—2. From ethylene chloride and alcoholic NH<sub>3</sub> (20 mols.) (Lellmann a. Würthner, A. 228, 226). The fraction (70°-100°) from the preparation of chloral contains ethylene and ethyldene chlorides, and if it be heated with alcoholic NH<sub>3</sub> at 110° for 9 hours, the ethylene chloride is converted into the diamine, while the ethyldene chloride is not affected (Hofmann, B. 4, 666).—3. From chloro-ethylene and NH<sub>3</sub> at 160° (Engel, Bl. [2] 48, 96).—4. By reducing cyanogen with tin and HCl (Fairley, A. Suppl. 3, 872).

*Preparation.*—A nearly theoretical yield of the hydrochloride is obtained when ethylene chloride (42 g.) is heated in a sealed tube to 115°-120° with 33 p.c. aqueous ammonia (510 c.c.). The crystals are washed with absolute alcohol until the washings cease to colour Nessler's solution. The alcohol yields a fresh crop of crystals containing ammonium chloride and di-ethylene-diamine hydro-chloride. The hydrate of the free base is obtained by the addition of freshly fused and powdered caustic soda to the chloride, then adding soda-lime and distilling. The anhydrous base is obtained from this hydrate by again heating with fused soda in a sealed tube for several hours (Kraut, A. 212, 254).

*Properties.*—Volatile alkaline liquid; it is very difficult to dry, requiring treatment with sodium. V. sol. water. It forms a hydrate B<sup>2</sup>aq [10°] (118°). S.G. 1<sup>a</sup> 0.970, not miscible with benzene or ether.

*Reactions.*—1. *Nitrous acid* forms nitrogen and ethylene oxide.—2. EtI forms C<sub>2</sub>H<sub>4</sub>N<sub>2</sub>H.Et<sub>2</sub>I, whence C<sub>2</sub>H<sub>4</sub>N<sub>2</sub>H.Et<sub>2</sub>aq, which is in turn converted by EtI into C<sub>2</sub>H<sub>4</sub>N<sub>2</sub>H.Et<sub>2</sub>I, whence moist Ag<sub>2</sub>O yields a volatile base whence C<sub>2</sub>H<sub>4</sub>N<sub>2</sub>H.Et<sub>2</sub>I, and C<sub>2</sub>H<sub>4</sub>N<sub>2</sub>.Et<sub>2</sub>I may be obtained. The two last iodides when treated with moist Ag<sub>2</sub>O leave fixed bases. C<sub>2</sub>H<sub>4</sub>N<sub>2</sub>Me<sub>2</sub>I<sub>2</sub> has also been prepared. The compound C<sub>2</sub>H<sub>4</sub>N<sub>2</sub>Et<sub>2</sub>H.Br<sub>2</sub> may also be obtained from ethylene-diamine and di-ethylamine (Hofmann, Pr. 11, 423); it gives C<sub>2</sub>H<sub>4</sub>N<sub>2</sub>Et<sub>2</sub>(HAuCl<sub>4</sub>)<sub>2</sub>. C<sub>2</sub>H<sub>4</sub>N<sub>2</sub>H.Et<sub>2</sub>Br<sub>2</sub> is one of the products of the action of ethylamine on C<sub>2</sub>H<sub>4</sub>Br<sub>2</sub>; the corresponding base C<sub>2</sub>H<sub>4</sub>N<sub>2</sub>H.Et<sub>2</sub>aq crystalline; it may be dehydrated by repeated distillation over baryta, when its V.D. (H=1) is 57.61 (calc. 58). The hydrated base C<sub>2</sub>H<sub>4</sub>N<sub>2</sub>H.Et<sub>2</sub>aq has a V.D. 38.2, showing dissociation (Hofmann, Pr. 10, 597). By co-

**Tri-ethylene-tetramine**  $(C_2H_5)_3N_4H_4$ . Occurs among the products of the action of ethylene bromide on ammonia, but is best obtained pure by treating ethylene-diamine with  $C_2H_5Br$ , and separated from its hydrobromide by moist  $Ag_2O$ . Strongly alkaline liquid.  $-B^{\circ}2H_2PtCl_6$ : pale yellow, amorphous, powder, almost insol. water. By the action of diethylamine on ethylene bromide at  $100^{\circ}$  there is formed  $(C_2H_5)_3N_4Et_4H_4Br$ , together with the compound  $(C_2H_5)_3N_4Et_2H_4Br$ , already mentioned. If the mixture be treated with  $Ag_2O$  and the liberated bases distilled with steam the volatile diethylamine and tetra-ethylene-diamine pass off, while the fixed octo-ethyl-tri-ethylene tetrammonium hydroxide  $(C_2H_5)_3N_4Et_8H_4(OH)$ , remains behind. It forms the following salts:  $(C_2H_5)_3N_4Et_8H_4Cl_2PtCl_6$ : small crystalline plates, almost insol. water. —  $(C_2H_5)_3N_4Et_8H_4Cl_4AuCl_4$ . —  $(C_2H_5)_3N_4Et_8H_4I_4$ : white crystals (from alcohol); v. sol. water. Further treatment with  $EtI$  gives  $(C_2H_5)_3N_4Et_{10}H_4I_4$ , which forms very fine crystals; m. sol. alcohol.

**Penta-ethylene tetramine**  $(C_2H_5)_5N_4H_4$ . When ethylene bromide is heated with ethylamine to  $100^{\circ}$  the following products result, besides  $NEtHBr$ :  $C_2H_5N_4Et_5H_4Br$ ,  $(C_2H_5)_2N_4Et_4H_4Br$ ,  $(C_2H_5)_3N_4Et_3H_4Br$ ,  $(C_2H_5)_4N_4Et_2H_4Br$ ,  $(C_2H_5)_5N_4EtH_4Br$ ,  $(C_2H_5)_6N_4H_4Br$ . The bases corresponding to the first four salts have already been mentioned as being volatile. The product is therefore treated with moist  $Ag_2O$  and then distilled with steam; the residual liquid is powerfully alkaline and consists chiefly or altogether of  $(C_2H_5)_5N_4EtH_4(OH)$ . The salts of this base crystallise with difficulty. Hofmann describes  $(C_2H_5)_5N_4EtH_4Cl_2PtCl_6$  and the aurochloride  $(C_2H_5)_5N_4EtH_4Cl_4AuCl_4$  as amorphous or indistinctly crystalline and sl. sol. water.  $EtI$  forms  $(C_2H_5)_5N_4Et_2H_4I_4$  and  $(C_2H_5)_6N_4H_4I_4$ .

**Hexa-ethylene tetramine**  $(C_2H_5)_6N_4H_4$ . The ethyl-bromide  $(C_2H_5)_6N_4H_4Br$  is formed as above, but is better prepared by the action of ethylene bromide on  $C_2H_5N_4Et_5H_4$  or  $(C_2H_5)_5N_4EtH_4$ .

**ETHYLENE DIISOAMYL DISULPHIDE**  $C_2H_4(SC_4H_9)_2$ . ( $245^{\circ}$ – $255^{\circ}$ ). From ethylene bromide and sodium isoamyl mercaptan (Ewerlöf, *B. 4*, 716). Gives  $C_2H_4(SOC_4H_9)_2$  [ $145^{\circ}$ – $150^{\circ}$ ] on oxidation.

**ETHYLENE-ANILINE v. DI-PHENYL-ETHYLENE-DIAMINE.**

**ETHYLENE-BENZOATE v. Benzoyl derivative of GLYCOL.**

**ETHYLENE-DI-BENZOYL CARBOXYLIC ACID v. DI-PHENYL-ETHYLENE DIKETONE CARBOXYLIC ACID.**

**ETHYLENE-BENZYL-CARBOXYLIC ACID v. DI-PHENYL-BUTANE DI-CARBOXYLIC ACID.**

**ETHYLENE BROMIDE**  $C_2H_4Br_2$ , i.e.  $CH_2Br.CH_2Br$ . *Di-bromo-ethane*. [ $9^{\circ}$ – $2^{\circ}$ ]. ( $131^{\circ}$  cor.). S.G.  $\frac{4}{7}$  2.1890;  $\frac{16}{17}$  2.1720 (Perkin);  $\frac{41}{4}$  2.1767;  $\frac{10}{7}$  2.1901 (Thorpe, *C. J.* 37, 177);  $\frac{29}{2}$  2.1768 (Weegmann, *Z. P. C.* 2, 218). C.E. ( $0^{\circ}$ – $150^{\circ}$ ) 0.0096; ( $0^{\circ}$ – $100^{\circ}$ ) 0.0061. V.D. 6.49 (calc. 6.56). M.M. 9.700 at  $15^{\circ}$  2 (Perkin, *C. J.* 45, 522). S.V. 91.65 (Schiff); 97.06 (Thorpe).

**Formation.**—1. By combination of bromine with ethylene (Balard, *A. Ch.* [2] 82, 875; Löwig, *Das Brom*, Heidelberg, 1829; Serullas, *A. Ch.* [2] 89, 228; D'Arcet, *J. pr.* 6, 28; Regnault, *A. Ch.* [3] 59, 858; Hofmann, *C. J.*

13, 67).—2. By bromination of ethyl bromide in presence of  $AlBr_3$  (Tavildaroff, *B.* 6, 1459; 13, 2403; *Bl.* [2] 34, 346).

**Preparation.**—Ethylene is passed through a series of bottles containing bromine covered by water; the product is washed with alkali, dried with  $CaCl_2$ , and distilled (Erlehmeyer, *A. Bunte*, *A.* 168, 64).

**Properties.**—Colourless liquid with pleasant smell; below  $9^{\circ}$  it is a crystalline mass. Insol. water, sol. alcohol and ether.

**Reactions.**—1. *Alcoholic potash* on boiling gives vinyl bromide and acetylene.—2.  $KHS$  forms  $C_2H_4(SH)_2$ .—3.  $K_2S$  gives  $C_2H_4S$  and  $C_2H_4S_2$ .—4.  $Ag_2O$  produces  $C_2H_4(OAc)_2$ .—5. *Alcoholic KOAc* forms  $C_2H_4(OH)(OAc)$ .—6.  $KCy$  forms  $C_2H_4(CN)_2$ .—7. *Ammonia* forms ethylene-diamine, di-ethylene-diamine, tri-ethylene-diamine, &c.—8. *Water* at  $160^{\circ}$  forms aldehyde (Carius, *A.* 131, 172); Kriwaxin (*Z.* [2] 7, 268) obtained no aldehyde. But when excess (26 pts.) of water is used at  $100^{\circ}$  glycol is formed (Niederist, *A.* 196, 354). Water and  $PbO$  at  $220^{\circ}$  form aldehyde (Eltekoff, *B.* 6, 558; Nevole, *B.* 9, 447).—9. *Alcohol* at  $160^{\circ}$  gives water, aldehyde, ethyl bromide, and ether (Carius).—10. Fuming  $H_2SO_4$ ,  $SO_2$ , or  $ClSO_3H$  at  $100^{\circ}$  form  $CH_3Br.CH_2SO_3H$  (Wroblewsky, *Z.* [2] 4, 563; 5, 281).—11. Reduced in presence of water or alcohol by zinc slowly, but more quickly by the copper-zinc couple, the product being ethylene (Gladstone, *A. Tribe*, *C. J.* 27, 406). Ethylene is also formed by heating  $C_2H_4Br_2$  with aqueous  $KI$ .—12. Water and  $Ag_2CO_3$  form glycol. Water and  $Ag_2O$  give aldehyde (Beilstein, *A. Wiegand*, *B.* 15, 1368).—13.  $Ag_2SO_3$  in benzene forms  $(CH_3Br.CH_2)_2SO_3$ .  $Ag_2SO_3$  in water gives  $(CH_3Br.CH_2)_2SO_3H$  (*B.* a. W.).—14. Ethylene bromide (188 g.) boiled with water (1,000 g.) and  $KOH$  (112 g.) is completely converted (in 6 hours) into  $KBr$  and vinyl bromide (Stempnewsky, *A.* 192, 240).—15. Boiling with dilute  $Na_2CO_3$  forms glycol.—16. Boiled with aqueous sodium sulphite it probably forms sodium isethionate, thus:  $C_2H_4Br_2 + Na_2SO_3 + H_2O = HO.C_2H_4.SO_3Na + NaBr + HBr$  (James, *C. J.* 43, 44), as well as ethane di-sulphonic acid (Strecker, *A.* 148, 90).—17.  $SbCl_5$  form  $CH_3Cl.CH_2Br$  (Henry, *C. R.* 97, 1491).—18.  $EtI$  forms  $EtBr$ ,  $(C_2H_5)_3S$ ,  $Et_2SBr$ , and perhaps  $(C_2H_5)_3S.EtBr$  (Dehn, *A. Suppl.* 4, 83; *B.* 2, 479; Masson, *C. J.* 49, 253).—19. Fuming  $HNO_3$  forms bromo-acetic acid and  $CB_2(NO_2)_2$  (Kachler, *M.* 2, 559).—20. Boiling conc.  $HIAg$  form ethylene iodide (Sorokin, *Z.* 1870, 519).—21. With *sodium-aceto-acetic ether* it gives  $CH_3.CO.O.C(CH_3)_2$ , acetyl-trimethylene carboxylic ether and very small quantities of  $CH_3.C-O.CH_3$  (Perkin, *jun.*, *C. J.* 51, 822).

22. *Di-sodium aceto-acetic di-carboxylic ether*  $CO_2Et.CH_2.CO_2$ . The resultant acid when boiled with water gives acetyl-propyl alcohol and  $2CO_2$  (Perkin).—23. *Potassium phthalimide* at  $200^{\circ}$  forms bromo-ethyl-phthalimide  $C_6H_4CO_2N.C_2H_4Br$  which when heated with concentrated hydric bromide at  $194^{\circ}$

forms the hydrobromide of bromo-ethylamine  $\text{CH}_3\text{Br} \cdot \text{CH}_2\text{NH}_2\text{Br}$  [ $155^\circ$ – $160^\circ$ ]. Diluted  $\text{H}_2\text{SO}_4$  decomposes bromo-ethyl-phthalimide forming oxyethylamine  $\text{CH}_3\text{OH} \cdot \text{CH}_2\text{NH}_2$  (Gabriel, *B.* 21, 566).

**ETHYLENE BROMO-IODIDE** v. **BROMO-iodo-ETHANE**.

**ETHYLENE CARBAMATE**  $\text{C}_2\text{H}_4(\text{OCONH}_2)_2$ . [149°]. Formed by the action of chloro-formic amide on glycol, the later being in excess (Gattermann, *A.* 244, 42). Crystalline flocculent mass. Sl. sol. ether,  $\text{CS}_2$ , v. sol. hot water, alcohol,  $\text{HOAc}$ .

**ETHYLENE DI-CARBAMIC ETHER**

$\text{C}_2\text{H}_4(\text{NH} \cdot \text{CO} \cdot \text{OC}_2\text{H}_5)_2$ . *Ethylene diurethane*. [112°]. Prepared by adding ethylene-diamine to an ethereal solution of ethyl chloro-carbonate and purified by distillation under 30 mm. Colourless needles. V. sol. alcohol and ether, v. sl. sol. water (Fischer a. Koch, *A.* 232, 228).

**ETHYLENE CARBONATE**  $\text{C}_2\text{H}_4\text{CO}_3$ . [39°]. (236°). From glycol and  $\text{COCl}_2$  (Nemirowsky, *J. pr.* [2] 28, 439). Needles (from ether). V. sol. water, alcohol, and warm ether.

**ETHYLENE DI-CARBOXYLIC ACID** v. **FUMARIC ACID**.

Ethylene tetra-carboxylic acid  $\text{C}_2\text{H}_2\text{O}_6$  i.e.  $(\text{CO}_2\text{H})_2\text{C}(\text{CO}_2\text{H})_2$ . The free acid decomposes very readily.

**Salts**.— $\text{K}_2\text{H}_2\text{A}^{4m}$ : from the ether by conc.  $\text{KOH}$  aq.— $\text{Ca}_2\text{H}_2\text{A}^{4m}$  7aq.— $\text{Ag}_2\text{H}_2\text{A}^{4m}$ .

**Ethyl ether**  $\text{Et}_2\text{A}^{4m}$ . [58°]. (325°–328°). Formed by the action of  $\text{NaOEt}$  on chloro-malonic ether (Conrad a. Guthzeit, *A.* 214, 76). Formed also by the action of iodine (2 mols.) on di-sodio-malonic ether (2 mols.) in absolute alcohol (Bischoff a. Bach, *B.* 17, 2781). Monoclinic tables. V. a. sol. ether or boiling alcohol, insol. water. Does not combine with bromine. Prepared by digesting chloro-malonic ether, diluted with anhydrous ether, for 20 hours with sodium; yield 50 p.c. of the theoretical. By heating with alcohol and aqueous  $\text{HCl}$  to  $190^\circ$  it yields fumaric acid. By zinc-dust and  $\text{HCl}$  it is reduced to ethane tetra-carboxylic acid (Conrad a. Guthzeit, *B.* 16, 2631).

**ETHYLENE CHLORHYDRIN** v. **CHLORO-ETHYL ALCOHOL**.

**ETHYLENE CHLORIDE**  $\text{C}_2\text{H}_4\text{Cl}_2$

i.e.  $\text{CH}_2\text{Cl} \cdot \text{CH}_2\text{Cl}$ . *Di-chloro-ethane*. Mol. w. 99. (83.6°) (Thorpe, *C. J.* 37, 182); (83.7° cor.) (Perkin, *C. J.* 45, 528). V.D. 8.42 (calc 3.42). S.G.  $\frac{1}{4}$  1.2808 (Th.);  $\frac{1}{2}$  1.2656 (Schiff, *A.* 220, 96);  $\frac{3}{4}$  1.2521 (Brühl, *A.* 203, 10); 1.2501 (Weegmann, *Z. P. C.* 2, 218);  $\frac{1}{2}$  1.2599;  $\frac{3}{4}$  1.2480 (P.). C.E. (0°–10°) .001162; (0°–50°) .001218 (T.); (0°–8° to 83.6°) .001269 (S.). S.V. 85.84 (Thorpe); 87.2 (Ramsay); 85.24 (Schiff). M.M. 5.485 at  $14.4^\circ$  (Perkin).  $\mu_D$  1.144 (W.).  $\mu_D$  1.4502.  $R_\infty$  34.12 (B.). H.F.p. 34.280 (Th.). H.F.v. 33.120 (Th.).

Discovered in 1795 by the four Dutch chemists (v. **ETHYLENE**) and hence called 'Dutch liquid.' Produced by admitting ethylene and moist chlorine simultaneously into a large globe. It may also be prepared by passing ethylene through a slightly heated mixture of  $\text{MnO}_2$  (2 pts.),  $\text{NaCl}$  (3 pts.), water (4 pts.), and  $\text{H}_2\text{SO}_4$  (5 pts.). Formed also by passing ethylene into  $\text{SbCl}_5$ . The product obtained from any one of these reactions is washed with alkali, dried over  $\text{CaCl}_2$ ,

and rectified (Liebig, *A.* 1, 213; 9, 20; Dumas, *A. Ch.* [2] 48, 185; Wöhler, *P.* 13, 297; Laurent, *A. Ch.* [2] 63, 377; Regnault, *A. Ch.* [2] 68, 801; 69, 251; 71, 871; Limpricht, *A.* 94, 245; Maguti, *A. Ch.* [3] 16, 6, 14; Pierre, *C. R.* 25, 430). It is formed also by heating glycol with excess of  $\text{HCl}$  in sealed tubes at  $100^\circ$  (Schorlemmer, *C. J.* 89, 144). It is obtained in large quantity, together with some of its chlorinated derivatives, from the by-products in the manufacture of chloral (Krämer, *B.* 3, 257).

**Properties**.—Oil, with sweetish odour; sol. alcohol and ether. Dissolves phosphorus. Not affected by  $\text{H}_2\text{SO}_4$  at  $100^\circ$ , but at  $130^\circ$  carbon is separated (Oppenheim, *B.* 2, 212). Burns with green flame. Ethylene chloride may be used with great advantage as an anæsthetic in operations on the eye (Dubois a. Roux, *Compt. rend. Soc. Biol.* 4, 584; *C. R.* 108, 191).

**Reactions**.—1. Its vapour passed through a red-hot tube forms carbon, naphthalene, chloride of carbon, &c.—2. When covered with water and exposed to sunshine it is decomposed, yielding  $\text{HCl}$  and acetic ether.—3. It is chlorinated by  $\text{Cl}$  in heat or light.—4. Dry ammonia does not act upon it, but when dissolved in water or alcohol it forms the various ethylene-amines (Robiquet a. Colin, *A. Ch.* [2] 1, 213; 2, 206).—5. Potassium attacks it violently, forming hydrogen, vinyl chloride, and other products.—6. Aqueous potash has little action, but alcoholic potash gives ethylene and vinyl chloride (Maurin, *C. R.* 68, 931).—7.  $\text{KHS}$ ,  $\text{K}_2\text{S}$ ,  $\text{K}_2\text{S}_2$ , and  $\text{K}_2\text{CS}_2$  give the corresponding ethers of ethylene.—8.  $\text{PCl}_5$  at  $190^\circ$  yields  $\text{CHCl}_2 \cdot \text{CH}_2\text{Cl}$  ( $121^\circ$ – $133^\circ$ ) and  $\text{CHCl}_2 \cdot \text{CHCl}_2$  ( $133^\circ$ – $146^\circ$ ) (Colson a. Gautier, *A. Ch.* [6] 11, 81).

**ETHYLENE CHLORO-BROMIDE** v. **CHLORO-BROMO-ETHANE**.

**ETHYLENE CHLORO-IODIDE** v. **CHLORO-iodo-ETHANE**.

**ETHYLENE CHLORO-THIOCYANATE** v. **CHLORO-ETHYL SULPHOCYANIDE**.

**ETHYLENE CYANIDE** v. *Nitrile of Succinic acid*.

**ETHYL-DI-ETHYL-DI-AMIDO-DI-BENZOIC ACID**. *Ethylether*.  $\text{C}_2\text{H}_4(\text{NEt} \cdot \text{C}_6\text{H}_4 \cdot \text{CO}_2\text{Et})_2$ . [98°– $100^\circ$ ]. From  $\text{C}_2\text{H}_4(\text{NH} \cdot \text{C}_6\text{H}_4 \cdot \text{CO}_2\text{H})_2$  by  $\text{KOH}$  and  $\text{Et}$  (Schiff a. Parenti, *A.* 226, 246). Doubly refracting prisms (from alcohol). Insol. water.

**ETHYLENE-ETHYL-AMINES** v. *Ethyl derivatives of ETHYLENE-AMINES*.

**ETHYLENE DIETHYL CARBONATE**

$\text{C}_2\text{H}_4(\text{O} \cdot \text{CO} \cdot \text{Et})_2$ . (226°). From sodium glycol  $\text{C}_2\text{H}_4(\text{ONa})_2$  and  $\text{ClCO}_2\text{Et}$  in ether (Wallach, *A.* 226, 82). Split up by long boiling into carbonic ether and ethylene carbonate.

**ETHYLENE-ETHYL-PROSPHINE** v. **ETHYL-PROSPHINE**.

**ETHYLENE-DI-ETHYL DI-SULPHIDE**

$\text{C}_2\text{H}_4(\text{SEt})_2$ . (212°). Formed by adding ethylene bromide to a boiling solution of sodium mercaptide (1 pt.) in ether (3 pts.) (Ewerlöt, *B.* 4, 716 Beckmann, *J. pr.* [2] 17, 468). Decomposed by heat. Converted by  $\text{EtI}$  at  $100^\circ$  into  $\text{SEt}_2\text{I}$  and  $\text{C}_2\text{H}_5\text{S}$  (Braun, *B.* 20, 2967).

**ETHYLENE-DI-ETHYL DI-SULPHONE**

$\text{C}_2\text{H}_4(\text{SO}_2\text{Et})_2$ . *Ethylene disulphinic ether*. [187°]. Formed by oxidising ethylene-di-ethyl di-sulphoxide with  $\text{KMnO}_4$  (Ewerlöt; Beckmann, *J. pr.* [2] 17, 468). Also from sodium

ethane sulphinate and ethylene bromide, and from sodium ethylene disulphinate and EtBr (Otto a. Casanova, *J. pr.* [2] 80, 172; 86, 433). Short needles, sol. hot water and alcohol, sl. sol. ether, benzene,  $\text{CHCl}_3$ , and conc.  $\text{HNO}_3$ . Not affected by reducing agents,  $\text{PCl}_5$ , or  $\text{KMnO}_4$ . Nascent hydrogen in alkaline solution converts it into sodium ethane-sulphinat and alcohol. Successive treatment with aqueous  $\text{KOH}$  and  $\text{BzCl}$  gives  $\text{SO}_2\text{Et}.\text{CH}_2.\text{CH}_2.\text{OBz}$  [118°]. It is uncertain whether ethylene di-ethyl di-sulphone has the constitution  $\text{C}_2\text{H}_4\{\text{S}(\text{O})_2\text{Et}\}_2$ , or whether it is not rather the ethyl ether of ethane disulphinic acid, under which it has also been described.

**ETHYLENE-DI-ETHYL DI-SULPHOXIDE**  $\text{C}_2\text{H}_4(\text{SOEt})_2$ . [170°]. Got by oxidising ethylene-di-ethyl di-sulphide with  $\text{HNO}_3$  (S.G. 1.2), neutralising, evaporating, and extracting with alcohol (Beckmann, *J. pr.* [2] 17, 468). White scales, sol. water and alcohol, insol. ether. Reduced by  $\text{Zn}$  and  $\text{H}_2\text{SO}_4$ , or by  $\text{HI}$  to the corresponding sulphide. Attacked by  $\text{PCl}_5$ . Reduces  $\text{KMnO}_4$ .

*Combination.*—With nitric acid it forms, on evaporation, an acid syrup  $\text{C}_2\text{H}_4(\text{SOEt})_2.\text{HNO}_3$ .

**ETHYLENE ETHYL DI-THIO-DI-CARBONATE** v. ETHYL THIO-CARBONATES.

(a) **ETHYLENE-DI-ETHYL-DI-UREA**  $\text{C}_2\text{H}_4\text{N}_2\text{O}_2$ , i.e.  $\text{C}_2\text{H}_4(\text{NEt.CO.NH}_2)_2$ . [124°]. From di-ethyl-ethylene-diamine, hydrobromide, and silver cyanate (Volhard, *Pr.* 11, 268; *A.* 119, 349). Flat needles (from alcohol). V. sol. cold water, v. e. sol. alcohol, insol. ether. Boiling  $\text{KOH}$ aq gives  $\text{NH}_3$ ,  $\text{CO}_2$ , and  $\text{C}_2\text{H}_4(\text{NEtH})_2$ .— $\text{B}'\text{H}_3\text{PtCl}_4$ : orange grains, decomposed by hot water.

(b) **Ethylene-di-ethyl-di-urea**  $\text{C}_2\text{H}_4(\text{NH.CO.NHEt})_2$ . [201°]. From ethylene-diamine and cyanic ether (Volhard). Small needles, v. sol. hot, sl. sol. cold, water, v. sl. sol. alcohol. Decomposed by boiling  $\text{KOH}$ aq, giving ethylamine and ethylene diamine. Is not basic.

**ETHYLENE GLYCOL** v. GLYCOL.

**ETHYLENE HEPTYLIDENE DIOXIDE**  $\text{C}_2\text{H}_4.\text{CH} \begin{smallmatrix} \diagup \text{O} \diagdown \end{smallmatrix} \text{C}_7\text{H}_{13}$ . (c. 180°). Formed by heating heptio aldehyde (1 vol.) with glycol (3 vols.) at 130° for 8 days (Loehert, *Bl.* [2] 48, 337, 716). Formed also by heating a mixture of heptio aldehyde (ananthol) (1 vol.), glycol (2 vols.), and  $\text{HOAc}$  (1 vol.). Liquid.

**ETHYLENE-IMINE**  $\text{C}_2\text{H}_4\text{N}$ , i.e.  $\begin{smallmatrix} \text{CH}_2 \\ \diagdown \text{N} \diagup \end{smallmatrix} \text{CH}_2$ , or  $\text{C}_2\text{H}_4\text{N}_2$ , i.e.  $\begin{smallmatrix} \text{CH}_2.\text{NH}.\text{CH}_2 \\ \diagdown \text{NH}.\text{CH}_2 \diagup \end{smallmatrix}$ . [159°–163°]. V.D. 2.93. Formed by subliming ethylene-diamine hydrochloride (4 g.); the sublimate is dissolved in water and ppd. by potassio-bismuthic iodide, the pp. being then decomposed by  $\text{KOH}$  (Ladenburg a. J. Abel, *B.* 21, 758, 2706). Deliquescent porcelain-like mass. Its V.D. corresponds to the formula  $\text{C}_2\text{H}_4\text{N}_2$ , but when first prepared it is possibly  $\text{C}_2\text{H}_4\text{N}_2$ . Insol. ether, v. sol. alcohol; absorbs  $\text{CO}_2$  from the air. The base is perhaps identical with spermine.

*Salts.*— $\text{C}_2\text{H}_4\text{NHOCl}$ : tables, v. sol. water, insol. alcohol.— $\text{B}'\text{H}_3\text{PtCl}_4$ : yellow prisms.— $\text{B}'\text{H}_3\text{I}.\text{BiI}_4$ : garnet-red plates, insol. cold water.— $\text{B}'\text{H}_3\text{AuCl}_4$ : nacrous leaflets, decom-

posed by heating with water.— $\text{B}'\text{H}_3\text{Cl}_2.3\text{HgCl}_2$ : clusters of quill-like groups of needles.

**ETHYLENE IODIDE**  $\text{C}_2\text{H}_4\text{I}_2$ , i.e.  $\text{CH}_2\text{I}.\text{CH}_2\text{I}$ . [82°].

*Formation.*—1. By direct combination of iodine and ethylene in sunshine (Faraday, *Ann. Phil.* 18, 118), or by heating to 60° (Regnault, *A. Ch.* [2] 69, 387).—2. One of the products formed when EtI is passed through a red-hot tube (E. Kopp, *J. Ph.* [3] 6, 110).—3. From glycol and cold  $\text{HI}$ .—4. By heating ethylene chloride with  $\text{CaI}_2$  aq at 75° (Spindler, *A.* 231, 265; Van Romburgh, *R. T. C.* 1, 151).

*Preparation.*—A pasty mixture of iodine and absolute alcohol is saturated with ethylene and agitated, fresh quantities of iodine being added from time to time (Semenoff, *Zeit. Ch. Pharm.* 1864, 673).

*Properties.*—Colourless needles or prisms; may be readily sublimed in hydrogen or ethylene. Insol. water, v. sol. ether and boiling alcohol. Slowly split up, especially under the influence of light, into ethylene and iodine; this change takes place rapidly at 85°.

*Reactions.*—1. Chlorine gives iodine and ethylene chloride. Bromine acts in the same way.—2. Aqueous  $\text{KOH}$ aq has but little action; but boiling alcoholic potash gives ethylene and vinyl iodide.—3. Water at 275° gives ethane,  $\text{CO}_2$ , and iodine (Berthelot, *A. Ch.* [4] 3, 211). 4. Mercuric chloride in the cold forms  $\text{C}_2\text{H}_4\text{ClI}$ . At 100° it forms  $\text{C}_2\text{H}_4\text{Cl}_2$  (Maumené, *C. R.* 68, 727).—5. Silver picrate forms the compound  $\text{CH}_2\text{I}.\text{CH}_2.\text{O}.\text{C}_6\text{H}_4(\text{NO}_2)_3$  (70°), crystallising in light yellow prisms, insol. water, sl. sol. cold alcohol and ether, v. sol. chloroform (Andrews, *B.* 13, 244).

**ETHYLENE IODO-CHLORIDE**  $\text{CH}_2\text{I}.\text{CH}_2\text{Cl}$ . *Chloro-iodo-ethane*. (140° cor.) (Thorpe, *C. J.* 37, 189). S.G.  $\frac{2}{4}$  2.1644;  $\frac{123}{8}$  2.1336 (T.). Obtained by agitating an aqueous solution of  $\text{ICl}$  containing a trace of free iodine with ethylene iodide or ethylene (Maxwell Simpson, *Pr.* 11, 590; 12, 278). Colourless oil with sweet taste, sl. sol. water. Moist  $\text{Ag}_2\text{O}$  at 180° forms glycol. Silver at 160° gives  $\text{AgI}$ , ethylene, and ethylene chloride (Friedel a. Silva, *Bl.* [2] 17, 242).

**ETHYLENE LACTIC ACID** v. HYDROXYLIC ACID.

**ETHYLENE MALONIC ACID** v. TRI-METHYLENE DICARBOXYLIC ACID.

**ETHYLENE MERCAPTAN**  $\text{C}_2\text{H}_4(\text{SH})_2$ . (146°). S.G.  $\frac{223}{1}$  1.123. Formed by the action of alcoholic  $\text{KHS}$  on ethylene chloride or bromide (Löwig a. Weidmann, *P.* 49, 132; *A.* 36, 322; Kekulé, *K.* 1, 655). Liquid, v. sol. alcohol. Sol. aqueous alkalis. Oxidised by  $\text{HNO}_3$  to the acid  $\text{C}_2\text{H}_4(\text{SO}_3\text{H})_2$ . When  $\text{HCl}$  is passed through a mixture of ethylene mercaptan with chloral there is formed the compound  $\text{C}_2\text{H}_4(\text{S}.\text{CH}(\text{OH}).\text{OCl})_2$ , [116°], which crystallises from ether in shining plates (Fasbender, *B.* 21, 1476). In general ethylene mercaptan combines with aldehydes, with evolution of heat, forming additive products, which are decomposed by water into their constituents. When  $\text{HCl}$  is passed into equimolecular mixtures of ethylene mercaptan and an aldehyde, condensation takes place, an alkylated ethylene mercaptan being formed.

Salts.— $C_2H_4S_2Pb$ : light-yellow.— $C_2H_4S_2Cu$ : green.

*Di-methyl derivative*  $C_2H_4(SMe)_2$  (183°). From ethylene bromide, and NaSMe (Ewerlöt, B. 4, 716).

*Di-ethyl derivative*  $C_2H_4(SEt)_2$  (c., 211°).

*Di-isoamyl derivative*  $C_2H_4(SC_4H_9)_2$  (245°–255°). Gives on oxidation  $C_2H_4(SO_2C_4H_9)_2$  [145°–150°].

*Benzylidene derivative*  $C_2H_4SCH_2C_6H_5$  [29°]. From benzoic aldehyde, ethylene mercaptan, and HCl. Insol. water, sol. alcohol and ether (Fasbender, B. 20, 460; 21, 1476).

*p-Methoxy-benzylidene derivative*  $C_2H_4SCH_2C_6H_4OMe$ . [65°]. From anisic aldehyde and ethylene mercaptan (F.).

*Acetylene derivative*  $C_2H_4SCH_2CH_2C_2H_2$  [133°]. From glyoxal and ethylene mercaptan.

*Ethylidene derivative*  $C_2H_4SCH_2Me$  (175°). Oxidises to a disulphide [193°].

*Propylidene derivative*  $C_2H_4SCH_2Et$  (192°). Gives a disulphide [124°].

*Iso-propylidene derivative*  $C_2H_4SCH_2Me_2$  (171°). From acetone, ethylene mercaptan, and HCl (F.). Potassium permanganate gives by oxidation  $C_2H_4(SO_2)CMe_2$  [232°].

*Di-phenyl-methylene derivative*  $C_2H_4SCH_2Ph_2$  [106°].

*ω-Chloro-ethyl-ethyl derivative*  $EtSCH_2CH_2CH_2Cl$ . From ethylated ethylene mercaptan,  $EtSCH_2CH_2SH$  by treatment with KOH and glycolic chlorhydrin, the product,  $EtSCH_2CH_2SCH_2OH$  being then mixed with  $PCl_5$  in the cold (Demult, A. V. Meyer, A. 240, 312). Needles. Decomposed by distillation into  $EtCl$  and di-ethylene-di-sulphide.

**ETHYLENE-METHYL-*v.* METHYL-ETHYLENE.**

**ETHYLENE-NAPHTHALENE *v.* ACENAPHTHENE.**

**ETHYLENE-NAPHTHOIC ACID**

$C_2H_4C_{10}H_6CO_2H$ . [217°]. Colourless needles. Obtained by boiling its amide with alcoholic KOH (Gattermann, A. 244, 58).

*Amide*  $C_2H_4C_{10}H_6CONH_2$ . [198°]. Formed by the action of  $ClCONH_2$  on acenaphthene in presence of  $AlCl_3$ . Colourless plates.

**ETHYLENE-NAPHTHYL BENZYL KETONE**  $C_2H_4C_{10}H_6COCH_2C_6H_5$ . [114°]. From acenaphthene, phenyl-acetic chloride and  $AlCl_3$  (Päpcke, B. 21, 1342). Long plates (from alcohol). V. sol. hot alcohol.

**ETHYLENE-NAPHTHYL DI-PHENYLETHYL KETONE**  $C_2H_4C_{10}H_6COCHPh.CH_2Ph$ . [104°]. From the preceding by treatment with benzyl chloride and  $NaOEt$  (Päpcke, B. 21, 1343).

**ETHYLENE NITRITE**  $C_2H_4(O.NO)_2$ . (96°). S.G. 2 1-2156. Prepared by distilling glycercyl trinitrite with glycol (Bertoni, G. 15, 351). Yellow oil, sol. alcohol, ether, and chloroform. Gives a violet colouration with conc.  $H_2SO_4$ . When distilled with methyl alcohol it yields methyl nitrite and glycol. Gradually converted into oxalic acid on exposure to air. When inspired it produces vertigo and paralysis of the respiratory system.

Isomeric of ethylene nitrite  $C_2H_4(NO)_2$ ? [38°]. Formed by passing dry ethylene through liquid nitric peroxide, or by passing ethylene

into dry ether, to which  $N_2O$  is at the same time added by drops (Semenoff, *Zeit. Oh. Pharm.* 1864, 129). White four-sided prisms or tables, insol. water, v. sol. alcohol and ether. When a gaseous mixture of ethylene and  $N_2O$  is heated to 65° there is formed, besides the compound [38°], a pungent, volatile, and poisonous, heavy oil, which is perhaps identical with the oil described by Bertoni as the true ethylene nitrite.

**ETHYLENE NITRITE-NITRATE**

$C_2H_4(NO_2)(NO)$ ? S.G. 1.472. A pungent oil formed when ethylene is passed through a cooled mixture of  $HNO_3$  and  $H_2SO_4$  or into fuming  $HNO_3$  (Kekulé, Z. [2] 5, 601). Decomposed by distillation with steam, yielding  $NO$ , nitrous fumes, oxalic, glycollic, and glyoxylic acids. Bases produce the same bodies. Sodium-amalgam reduces it in alkaline solution to glycol, giving off  $NH_3$ .

**ETHYLENE-DI-OXAMIC ETHER**

$C_2H_4(NH.CO.CO.F)_2$ . From oxalic ether and ethylene-diamine, remaining in solution when the following body is added (Hofmann, B. 5, 247). Scales, sol. water and alcohol.

**ETHYLENE-OXAMIDE**  $C_2O_2N_2H_2C_2H_4$ . From oxalic ether and ethylene-diamine (Hofmann, B. 5, 247). Amorphous, insol. water and alcohol.

**ETHYLENE OXIDE**  $C_2H_4O$  i.e.  $\begin{matrix} CH_2 \\ \diagup \quad \diagdown \\ O \end{matrix}$

Mol. w. 44. (13.5°). S.G. 2 897. V.D. 1.42 (calc. 1.53). H.F.p. 18,090 (Th.). H.F.v. 17,220 (Th.). Formed by warming glycolic chlorhydrin (chloro-ethyl-alcohol)  $CH_2Cl.CH_2OH$  with potash and collecting in a receiver at -18° (Wurtz, C. R. 48, 101; 49, 898; 50, 1195; 53, 378; 54, 277; A. 110, 125; 114, 51; 116, 249; A. Ch. [3] 55, 418, 427; 69, 317; C. J. 15, 387). Formed also by treating  $C_2H_5Br$  or  $C_2H_5I$  with  $Ag_2O$  at high temperatures (Greene, C. R. 85, 624). From  $CH_2(OAc).CH_2Cl$  and KOH (Demole, A. 173, 125). Mobile colourless liquid. Miscible with water and alcohol. Does not unite with  $NaHSO_4$  or with  $NH_3$ . Cannot be dried by  $CaCl_2$ . Behaves as a strong base, uniting directly with  $HCl$ ,  $HOAc$ , &c. Ppts. from magnesium, aluminium, ferric, and cupric salts, the hydrates of the metals, e.g.

*Reactions.*—1. Sodium amalgam reduces it to alcohol, glycol and polyethylenic glycols being also formed.—2. Unites with  $HCl$  forming  $CH_2Cl.CH_2OH$ . The union  $C_2H_4O + HCl$ , both being gaseous, evolves 3,600 units of heat (Bertolot, C. R. 93, 185).—3. Unites with  $HOAc$ , giving  $CH_2(OH).CH_2(OAc)$ .—4.  $Ac_2O$  gives  $CH_2(OAc).CH_2(OAc)$  and the polyethylenic diacetates  $(C_2H_4O)_n.Ac_2O$ .—5. When heated with water in sealed tubes it forms glycol and the polyethylenic glycols.—6. Bromine (1 mol.) mixed with ethylene oxide (2 mols.), and cooled by a freezing mixture, forms  $(C_2H_4O)_2.Br_2$ , crystallising in prisms [65°], insol. water, sol. alcohol.—7. Ammonia forms oxy-ethyl-amine and compounds of the formula  $C_2H_4(OH)(OC_2H_4)_n.NH_2$ .—8. Heated with  $NaHSO_4$  in a sealed tube at 100° it gives  $CH_2(OH).CH_2.SO_3Na$  (Erlenmeyer, Z. [2] 4, 842).—9. Resinifies aldehyde when heated with it in a sealed tube.—10.  $PCl_5$  gives ethylene chloride.—11. Phosphonium iodide gives  $PH_3$  and ethylene iodide (De Girard, C. R. 101, 478).

**Di-ethylene dioxide**  $C_2H_4 \langle \text{O} \rangle C_2H_4$ . [9°].

(102°). S.G. 2 1.048. V.D. 3.10 (calc. 3.05). Formed by treating the compound  $(C_2H_5O)_2Br_2$  (v. *supra*) with  $H_2S$  or, better, with mercury in the cold (Wurtz). Liquid with faint odour. Sol. alcohol and ether, not attacked by ammonia.

**Polymeride of ethylene oxide**  $(C_2H_4O)_n$ . [56°]. Formed by leaving ethylene oxide for some months after addition of a very small fragment of fused potash or  $ZnCl_2$  (Wurtz, *Bl.* [2] 29, 530; C. R. 86, 1176). A trace of  $HCl$  will not effect the change. It is a nodular crystalline mass; v. sol. water, insol. ether. It does not reduce Fehling's solution.

**Chloro-ethylene oxide**  $C_2H_3ClO$ . (70°–80°). From  $CHCl:CHI$  (1 vol.) and water (45 vols) at 210° (Sabanejeff, *A.* 216, 268).

**Bromo-ethylene oxide**  $C_2H_3BrO$ . (c. 91°). From  $CHBr_2:CHI_2OH$  and  $KOH$  in  $MeOH$  (Demole, *B.* 9, 51).

**ETHYLENE-PHENANTHRAQUINOXALINE**

$C_{16}H_{12}N_2$  i.e.  $\begin{array}{c} C_6H_4-C-N-CH_2 \\ | \quad | \quad | \\ C_6H_4-C-N-CH_2 \end{array}$ . *Ethylene-di-phenylene-quinoxaline*. [181°]. Formed by mixing phenanthraquinone and ethylene-diamine in warm acetic acid solution (Mason, *B.* 19, 112). Distils undecomposed at a high temperature. Yellowish needles. V. sol. ether, benzene, and acetic acid, sl. sol. cold alcohol, insol. water.

**ETHYLENE-DI-PHENYL-DIAMINE** v. DI-PHENYL-ETHYLENE DIAMINE.

**ETHYLENE-DI-PHENYL-DI-CARBAMATE** v. *Ethylene ether of PHENYL-CARBAMIC ACID*.

**ETHYLENE-PHENYLENE-DIAMINE** v. PHENYLENE-ETHYLENE-DIAMINE.

**Ethylene-di-phenylene-m-tetramine**  $(3.1)C_6H_4(NH_2).NH.C_6H_4.NH.C_6H_4(NH_2)[1.3]$ . *Di-m-amido-di-phenyl-ethylene-diamine*. [107°]. Formed by reduction of di-m-nitro-di-phenyl-ethylene-diamine. Silvery needles or tables (from hot water). Nearly insol. cold water.

**Salts**.—With nitrous acid they give a brown colouration.— $B^+H_2Cl_2$ : soluble colourless plates. The picrate forms long brown sparingly soluble needles. The tin-double-chloride is sl. sol. cold water (Gattermann a. Hager, *B.* 17, 779).

**Di-ethylene-di-phenylene-tetramine**  
 $\begin{array}{c} N-C_6H_4-NH_2 \\ | \quad | \\ C_6H_4 \quad C_6H_4 \\ | \quad | \\ N-C_6H_4-NH_2 \end{array}$ . [221°]. Prepared by reduction of dinitroso-diphenyl-diethylene-diamine (Morley, *B.* 12, 1796). Silvery leaflets. Sl. sol. alcohol, ether, and  $C_6H_6$ . Violet colouration with  $FeCl_3$ .

**ETHYLENE-DI-PHENYLENE-NITRAMINE** v. DI-NITRO-DI-PHENYL-ETHYLENE-DIAMINE.

**ETHYLENE-DI-PHENYL-DI-SULPHONE** v. DI-PHENYL-ETHYLENE-DI-SULPHONE.

**ETHYLENE-DIPHTHALIMIDE**  $(C_6H_4C_2O_2N)_2C_2H_4$ . [232°]. From potassium phthalimide (10 g.) and ethylene bromide (12 g.) at 200°, the chief product of the reaction being  $C_6H_4C_2O_2N.C_6H_4Br$  [83°] (Gabriel, *B.* 20, 2224). Long lustrous needles (from  $HOAc$ ). Fuming  $HCl$  at 200° splits it up into ethylene-diamine and phthalic acid.

**ETHYLENE PROPYLIDENE DISULPHONE**

v. **ETHYLENE MERCAPTAN**.

**ETHYLENE DIPROPYL DISULPHONE**  $C_6H_5(SO_2Pr)_2$ . [155°]. From sodium ethane disulphinate and propyl bromide (Otto, *J. pr.* [2] 36, 446). Iridescent prisms.

**ETHYLENE-DI-QUINOLINE**  $C_{20}H_{14}N_2$  i.e.

[106.5°]. Prepared by the action of  $HI$  and amorphous phosphorus on acetylene-di-quinoline [147°], itself prepared from *p*-amido-*(Py. 3)*-styryl-quinoline by treatment with *o*-nitrophenol, glycerin, and  $H_2SO_4$  (Balach, *B.* 22, 289). Glistening prisms (from hot water).

**ETHYLENE SELENOCYANIDE**  $C_2H_4(SeCy)_2$ . [128°]. From potassium selenocyanide and ethylene bromide (Proskauer, *B.* 7, 1281). White needles (from alcohol), insol. cold water and ether, sl. sol. hot water and cold alcohol. Boiling nitric acid oxidises it to  $C_2H_4(SeO_3H)_2$  which is deliquescent.

**ETHYLENE SULPHIDE**  $C_2H_4S$ . This perhaps constitutes the amorphous *pp*. obtained when ethylene bromide is mixed with alcoholic  $KHS$ . It is nearly insol. alcohol, ether, and  $CS_2$ . At 160° it changes to di-ethylene-disulphide (Löwig a. Weidmann, *P.* 49, 123). When ethylene sulphide is heated with  $MeI$  in a sealed tube at 65° it forms a sulphine iodide which resembles  $SMe_2I$  rather than  $(C_2H_5)_2SMeI$  in crystalline form and solubility (Masson, *C. J.* 49, 249).

**Di-ethylene di-sulphide**  $C_2H_4 \langle S \rangle C_2H_4$ . Mol. w. 120. [112°]. (200°). V.D. 4.28 (calc. 4.16). Formed by heating the preceding at 160° (Crafts, *A.* 124, 110). Obtained also by heating ethylene tri-thiocarbonate  $C_2H_4CS_3$  or ethylene mercaptide of mercury  $C_2H_4S_2Hg$  with  $C_2H_5Br$  at 150° (Husemann, *A.* 126, 280).

**Properties**.—Monoclinic prisms (from  $CS_2$ ), sol. alcohol and ether. Readily sublimed.

**Reactions**.—1. *Bromine* forms  $(C_2H_4)_2S_2Br_2$ , a yellow amorphous *pp*. [96°].—2. *Iodine* gives  $C_2H_4S_2I_2$  [133°]: black monoclinic needles.—3. Fuming  $HNO_3$  forms  $(C_2H_4)_2(SO)_2$ , below 100°, but above 150° it gives  $(C_2H_4)_2(SO_3)_2$  (Crafts, *A.* 125, 123).

**Combinations**.— $C_2H_4S.HgCl_2$ : crystalline *pp*. got by mixing alcoholic solutions of  $C_2H_4S_2$  and  $HgCl_2$ .— $C_2H_4S_2.HgI_2$ : minute trimetric tables.— $C_2H_4S_2.PtCl_4$ : amorphous orange powder.— $C_2H_4S_2.AuCl_3$ : vermilion *pp*.— $(C_2H_4S_2)_4AgNO_3$ : small monoclinic crystals; decomposing at 140°.

**Methylo-iodide**  $(C_2H_5)_2SMeI$ . From di-ethylene di-sulphide and  $MeI$  at 70° (Masson, *C. J.* 49, 238). Opaque white needles, v. sol. hot, sl. sol. cold, water, v. sol. alcohol, insol. ether. Sublimes above 100°, some  $(C_2H_5)_2S_2$  being regenerated.

**Methylo-tri-iodide**  $(C_2H_5)_3SMeI_3$ . [89°] (Masson); [93°] (Mansfeld, *B.* 19, 2658). From the methyl-iodide and iodine. Thin lustrous garnet-red plates, v. sol. hot, sl. sol. cold, alcohol, insol. ether.

**Di-methylo-iodide**  $(C_2H_5)_2S_2MeI_2$ . [208°]. **Methylo-nitrate**  $(C_2H_5)_2S_2MeNO_3$ . [172°]. From the iodide and  $AgNO_3$  (Masson). Pearly plates or rhombic crystals, v. e. sol. water,

m. soluble in hot alcohol, insoluble in ether.— $(C_2H_5)_2S_2MeNO_3AgNO_3$ : colourless barb-like crystals, v. e. sol. water, m. sol. alcohol, insol. ether; blackens in sunlight; detonates slightly when heated.

**Methylo-sulphate**  $\{(C_2H_5)_2S_2\}_2Me_2SO_3 \cdot 7H_2O$ . [127°]. From the iodide and  $Ag_2SO_3$ . Large deliquescent prisms (from water) or small needles (from alcohol). Decomposed by fusion.

**Methylo-chloride**  $(C_2H_5)_2S_2MeCl$ . [225°] (Mansfeld, B. 19, 2658). From the sulphate and  $BaCl_2$ . Needles or tables; v. sol. water, sl. sol. alcohol, insol. ether (Masson, C. J. 49, 242).  $(C_2H_5)_2S_2MeCl \cdot PtCl_4$ : orange crystalline powder, got by adding  $PtCl_4$  to a cold solution of the chloride.— $C_2H_5S_2PtCl_4$ : formed by digesting the preceding compound with boiling water.— $(C_2H_5)_2S_2MeCl \cdot 3PtCl_4$ : formed, together with the following, by adding  $PtCl_4$  to a hot solution of the methylo-chloride. Orange amorphous pp., insol. water, alcohol, ether, and dilute acids, sl. sol. hot conc.  $HCl$  aq., sol. conc.  $NH_4$  aq. Cold  $H_2S$  does not affect it, but it is decomposed by  $H_2S$  at 100°.— $C_2H_5S_2MeCl \cdot PtCl_4$ : obtained by fractionally ppg. a solution of the methylo-chloride with  $PtCl_4$ . Orange amorphous pp.— $C_2H_5S_2MeCl \cdot AuCl_3$ : light-yellow amorphous powder; decomposed by heating with water.— $C_2H_5S_2ClHgCl_2$ : needles and thin plates, obtained by mixing aqueous solutions of its components.

**Methylo-hydroxide**  $(C_2H_5)_2S_2MeOH$ . Formed in solution by treating a very dilute solution of the iodide with moist  $Ag_2O$  in the cold. It ppts. solutions of metallic salts and absorbs  $CO_2$  from the air. On boiling there is formed a white flocculent pp. and an oil  $C_{12}H_{24}S_4$ ; S.G.  $\frac{16}{15.3}$  1.044. This oil has a disagreeable odour, is insol. water, sol. alcohol and ether; volatile with steam. It combines with  $MeI$ . This oil is also formed when an aqueous solution of the chloride, iodide, sulphate, or nitrate is heated with potash or baryta-water. Mansfeld considers the oil to be  $C_4H_{10}S_2$ , and finds it can take up (2 mols. of) bromine.

**Methylo-picrate**  $(C_2H_5)_2S_2MeO \cdot C_6H_3(NO_2)_3$ . [193°]. Golden needles (Mansfeld).

**Benzilo-bromide**  $(C_2H_5)_2S_2C_6H_5Br$ . [146°]. From  $(C_2H_5)_2S_2$  and benzyl bromide at 150° (Mansfeld, B. 19, 2666). Trimetric crystals (from water). Sl. sol. water and alcohol. Potash (1 mol.) converts it on warming into oily  $C_{11}H_{18}S_2$ , which is slightly volatile with steam.

**Benzilo-chloride**  $(C_2H_5)_2S_2C_6H_5Cl$ . [143°]. From the bromide and  $AgCl$ . Colourless silky needles.

**Benzilo-iodide**  $(C_2H_5)_2S_2C_6H_5I$ . From di-ethylene di-sulphide and benzyl iodide at 100°. Pale-yellow needles, sl. sol. water, m. sol. alcohol, insol. ether.

**Benzilo-picrate**  $(C_2H_5)_2S_2C_6H_5OC_6H_3(NO_2)_3$ . [112°]. Golden needles.

[152°]?

**Formation.**—1. By the action of bromine upon a chloroform solution of ethylene mercaptan  $C_2H_4(SH)_2$  or of benzylidene-ethylene-di-

ethylene mercaptan with conc.  $H_2SO_4$  or with  $SO_2Cl_2$ .—3. By the action of hydroxylamine hydrochloride on an alkaline solution of ethylene mercaptan.

**Properties.**—Amorphous powder. Softens at 141°, melts at 152°. Almost insol. all solvents. Sol. phenol. Not volatile (Fasbender, B. 20, 462; 21, 1471). It forms a perbromide  $C_2H_4S_2Br_4$ : unstable brownish-red crystals.  $HNO_3$  gives ethylene disulphonic acid.

#### DI-ETHYLENE SULPHOBROMIDE

$(C_2H_5)_4S_2Br_2$ . Formed by heating ethyl sulphide with ethylene bromide and water (1 vol.) at 130° (Dehn, A. Suppl. 4, 83; cf. Masson, C. J. 49, 253). It is said to give  $(C_2H_5)_2S_2Cl_2 \cdot PtCl_4$ .

**ETHYLENE SULPHOCHLORIDE.** A name given by Guthrie to various oils got by the action of the chlorides of sulphur on ethylene (q. v.).

#### ETHYLENE DI-SULPHOCYANIDE

$C_2H_4(SCN)_2$ . [90°]. S.G.  $\frac{12}{12.8}$  1.28.

**Formation.**—1. By heating an alcoholic solution of ethylene chloride or bromide with an equivalent quantity of potassium sulphocyanide at 100° (Sonnenschein, J. pr. 65, 257; Buff, A. 96, 302; 100, 219; Glutz, A. 153, 313).—2. From  $KSCN$ ,  $C_2H_4Cl_2SCN$ , and alcohol (James, C. J. 43, 40).

**Properties.**—Stellate groups of small needles (from water) or large trimetric plates (from alcohol). Burning taste; blisters the skin. Its vapour excites sneezing.  $HNO_3$  oxidises it to ethane disulphonic acid  $C_2H_4(SO_3H)_2$ . Boiling aqueous  $KOH$  or baryta saponify it, forming sulphocyanides.

**Reactions.**—1. *Tin and hydric chloride* give  $CyS.C_2H_4.SH.Cl$ , which crystallises from alcohol in scales, and forms a tin double salt  $(C_2H_4NS.Cl)_2SnCl_2$  (Glutz). The corresponding compounds,  $C_2H_4NS.I$  which melts above 100°,  $C_2H_4NS.NO_3$  aq., and  $C_2H_4NS.SCy$  are crystalline.—2.  $PbI_2$  forms  $PbI_2S$  and  $C_2H_4(PbI_2CN)_2$  (Hofmann, A. Suppl. 1, 55).—3. A warm conc. solution of  $Na_2SO_3$  forms crystals of  $CH_3S.NO_3.Na_3$  (?), while the mother-liquor contains  $C_2H_4S_2O_2.Na_4$  (Glutz).

#### DI-ETHYLENE DI-SULPHONE

$C_2H_4 \begin{array}{c} SO_2 \\ \diagup \quad \diagdown \\ SO_2 \end{array} C_2H_4$ . Formed by heating di-ethylene di-sulphide with fuming  $HNO_3$  for 30 minutes at 150° (Crafts, A. 125, 124). Formed also by the action of di-bromo-ethane on sodium ethane disulphinate (Otto, J. pr. [2] 36, 446). Prisms, insol. ordinary solvents, m. sol. hot conc.  $HNO_3$ .

**ETHYLENE DISULPHONIC ACID v. ETHANE DISULPHONIC ACID.**

#### DI-ETHYLENE DISULPHOXIDE

$C_2H_4 \begin{array}{c} SO \\ \diagup \quad \diagdown \\ SO \end{array} C_2H_4$ . From di-ethylene di-sulphide and fuming  $HNO_3$  (Crafts, A. 124, 113; 125, 123). Formed also by treating  $(C_2H_5)_2S_2Br_2$  with water (Husemann, A. 126, 290). Rhombohedra or long white prisms; decomposed by heat without melting. V. sol. water, sl. sol. alcohol and ether. Chlorine passed into its solution gives a crystalline pp. of  $C_2H_4Cl_2S_2O_2$ .

**ETHYLENE THIO-AMMELINE**  $C_2H_4N_2S$ 

heating ethylene bromide, alcohol, and thio-ammeline to  $120^\circ$  (Rathke, *B.* 21, 874).

**Reactions.**—1. By passing *chlorine* through a solution of the hydrochloride in water an anhydride of 'tauroammeline' is formed. This anhydride forms plates, insol. water, sol. alkalis; it may be written  $\text{N} \begin{array}{c} \text{C}(\text{NH}_2) \cdot \text{N} \\ \diagup \quad \diagdown \\ \text{C} \quad \text{C} \end{array} \text{C.OH}$ .

2. Oxidation with  $\text{HNO}_3$  yields the compound  $C_2H_4N_2S_2O_3$ . This compound has been called 'tauro-di-ammeline,' and crystallises from water in transparent prisms. It does not melt below  $290^\circ$ . It reddens blue litmus, liberates  $\text{CO}_2$  from carbonates, and forms very soluble salts of K, Na, Ca, and Ba. Its ammoniacal solution gives with  $\text{AgNO}_3$  a pulverulent pp. not affected by light. On boiling with baryta it changes to 'tauro-ammelido'

$\text{N} \begin{array}{c} \text{C}(\text{NH}_2) \cdot \text{N} \\ \diagup \quad \diagdown \\ \text{CO} \quad \text{N} \end{array} \text{C}_2\text{H}_4\text{SO}_3\text{H}$  [c.  $267^\circ$ ], which forms moderately soluble crystals, and gives with ammoniacal copper solution a pp. of flat amethyst-coloured needles.

**ETHYLENE DI-THIO-CARBONATE**

$C_2H_4\text{COS}_2$ . [ $31^\circ$ ]. From ethylene-tri-thio-carbonate by treatment with moderately dilute nitric acid (Husemann, *A.* 126, 269). Long thin rectangular tables (from alcohol). May be distilled in a current of hydrogen; insol. water, v. sol. alcohol, ether, chloroform, and benzene.

Ethylene tri-thio-carbonate  $C_2H_4\text{CS}_3$ . [ $37^\circ$ ]. S.G. 1.477. From  $\text{Na}_2\text{CS}_3$  and an alcoholic solution of ethylene bromide (Husemann, *A.* 123, 83). Large yellow crystals (from ether-alcohol), with alliacious odour, sl. sol. alcohol, v. sol. benzene,  $\text{CS}_2$ , and chloroform. Converted by ammonia into ethylene mercaptan and ammonium sulphocyanide.  $\text{KHS}$  gives  $\text{K}_2\text{CS}_2$  and ethylene mercaptan. Fuming  $\text{HNO}_3$  gives  $C_2H_4(\text{SO}_3\text{H})_2$ .

**ETHYLENE THIO-UREA**  $C_2H_4N_2S$  *i.e.*

$\text{CS} \begin{array}{c} \text{NH} \\ \diagup \quad \diagdown \\ \text{NH} \end{array} \text{C}_2\text{H}_4$ . [ $194^\circ$ ]. An alcoholic solution of ethylene-diamine mixed with  $\text{CS}_2$  deposits in a short time amorphous  $C_2H_4N_2S_2$  (or  $\text{CS} \begin{array}{c} \text{S.NH}_2 \\ \diagup \quad \diagdown \\ \text{NH} \end{array} \text{C}_2\text{H}_4$  ?), insol. alcohol and ether, which, when boiled with water, gives off  $\text{H}_2\text{S}$ , leaving ethylene thio-urea (Hofmann, *B.* 5, 240). Prisms (from water). Sl. sol. ether, v. sol. alcohol. Tastes bitter. Not altered by digestion at high temperatures with  $\text{CS}_2$  and  $\text{PbO}$ .

**Combinations.**— $(C_2H_4N_2S)_3\text{HgCl}_2$ — $(C_2H_4N_2S)_2\text{PtCl}_4$ — $(C_2H_4N_2S)_2\text{H}_2\text{PtCl}_4$ : obtained by heating ethylene thio-urea with conc.  $\text{H}_2\text{SO}_4$ , diluting with water, and adding platinum chloride.

**Ethylene-di-thio-di-urea**  $C_2H_4N_2S_2$  *i.e.*  $C_2H_4(\text{NH.CS.NH})_2$ . The hydrobromide  $\text{B}^{\text{H}}\text{Br}$  is formed by boiling thio-urea with  $C_2H_4\text{Br}_2$  in alcohol (Andreasch, *M.* 4, 142). This salt forms long broad prisms, sol. cold water.  $\text{HCl}$  and  $\text{KClO}_4$  oxidise it to urea and  $C_2H_4(\text{SO}_3\text{H})_2$ . The hydrochloride  $\text{B}^{\text{H}}\text{HCl}$  forms geodes of slender needles.

**ETHYLENE-TOLYL- v. TOLYL-ETHYLENE-;** and *isgra.*

**ETHYLENE-DI-*p*-TOLYLENE-TETRA-AMINE**

$C_6H_4(\text{CH}_3)(\text{NH}_2).\text{NH.C}_2\text{H}_4.\text{NH.C}_6H_4(\text{CH}_3)(\text{NH}_2)$ . *Di-m-amido-di-p-tolyl-ethylene-diamine*. [ $159^\circ$  uncor.]. Formed by reduction of di-*m*-nitro-di-*p*-tolyl-ethylene-diamine (Gattermann & Hager, *B.* 17, 779). Long colourless needles. Sol. alcohol, sl. sol. water.

**ETHYLENE-DI-TOLYLENE-NITRAMINE v. DI-NITRO-DI-TOLYL-ETHYLENE-DIAMINE.****ETHYLENE-UREA**  $C_2H_4N_2O$  *i.e.*

$C_2H_4 \begin{array}{c} \text{NH} \\ \diagup \quad \diagdown \\ \text{NH} \end{array} \text{CO}$ . [ $131^\circ$ ]. Formed by heating ethylene-diamine with ethyl carbonate at  $180^\circ$  (Fischer & Koch, *A.* 232, 227). Needles v. sol. water and hot alcohol, sl. sol. ether. Gives with  $\text{HNO}_3$  a di-nitro-derivative without any evolution of gas (Franchimont, *R. T. C.* 6, 219).

**Ethylene-di-urea**  $C_2H_4N_2O_2$  *i.e.*  $C_2H_4(\text{NH.CO.NH})_2$ . [ $192^\circ$ ]. From silver cyanate and the hydrochloride of ethylene-diamine (Volhard, *Pr.* 11, 268). Prisms, sol. water and alcohol. Dissolves in  $\text{HClAq}$ , but separates unaltered on evaporation. Boiling conc.  $\text{KOH}$  gives ethylene-diamine,  $\text{CO}_2$ , and ammonia. With a solution of mercuric nitrate it gives a flocculent pp. It is immediately attacked by pure  $\text{HNO}_3$ , giving off  $\text{CO}_2$  and  $\text{N}_2\text{O}$  in equal volumes (Franchimont, *R. T. C.* 6, 219).— $\text{B}^{\text{H}}\text{H.PtCl}_4$ : orange-red prisms.— $\text{B}^{\text{H}}\text{HAuCl}_4$ : golden scales.

**ETHYLENE-DI-URETHANE v. ETHYLENE DICARBAMIC ETHER.****ETHYL-ETHANE CARBOXYLIC ACID v. BUTANE-CARBOXYLIC ACID.****ETHYL-ETHENYL CARBOXYLIC ACID v. BUTANE TRI-CARBOXYLIC ACID.****ETHYL ETHER v. ETHER.****ETHYL-ETHYLENE v. BUTYLENE.**

**TETRA-ETHYL FERRO-CYANIDE**  $\text{Et}_4\text{FeCy}_4$ . [ $214^\circ$ ]. Formed by the action of silver ferro-cyanide on ethyl iodide (Freund, *B.* 21, 935). Rhombic crystals (from chloroform). V. sol. water, alcohol, chloroform, insol. ether, petroleum ether, and  $\text{CS}_2$ . Is decomposed by conc.  $\text{H}_2\text{SO}_4$  with evolution of  $\text{CO}_2$ .  $\text{HgCl}_2$  gives a white pp.

**ETHYL-FLAVANILINE**  $C_{14}H_{13}N_2(C_2H_5)$ . Orange colouring matter.— $\text{B}^{\text{H}}\text{I}$ : long red needles. Formed by heating flavaniline with ethyl-iodide (Fischer & Rudolph, *B.* 15, 1502).

**ETHYL FLUORIDE**  $C_2H_5F$ . ( $-48^\circ$ ). V.D. 1.70. S. (gas) 1.98. Produced by distilling a mixture of fluor-spar, alcohol, and  $\text{H}_2\text{SO}_4$  or by warming  $\text{KFSO}_4$  with  $\text{KHF}_2$  (Reinsch, *J. pr.* 19, 514; Fremy, *A.* 92, 247). Prepared by passing  $\text{EtI}$  over  $\text{AgF}$  heated to  $40^\circ$  in leaden tubes, and collected over mercury in dry glass vessels (Moissan, *C. R.* 107, 260). Gas, v. sol.  $\text{EtI}$  and  $\text{EtBr}$ . Under 8 atmospheres' pressure it liquefies at  $19^\circ$ . Burns with a blue flame. Heated to dull redness in a glass bulb it gives a mixture of hydrocarbons together with traces of fluoride of silicon. Subjected to a weak induction spark its volume increases, and it gives hydrofluoric acid, and small quantities of acetylene and ethylene, but no free carbon. Subjected to a strong induction spark it gives free carbon, also acetylene, ethylene, propylene, &c. Passed through a platinum tube heated to dull redness it

yields hydrofluoric acid mixed with hydrocarbons, partly capable of being absorbed by sulphuric acid, and a little free carbon is deposited. Anesthetic. In large quantities the excitement is followed by death (Moissan, C. R. 107, 992).

**ETHYL-FORMAMIDE** *v.* *Formyl derivative of ETHYLAMINE, and also under FORMIC ACID.*

***α*-DI-ETHYL-FORMAMIDINE**

$\text{HC}(\text{NEt}_2)_2\text{NH}$ . *Form-imid-di-ethyl-amide*. Prepared by allowing an absolute alcoholic solution of the hydrochloride of formimido-ether (1 mol.) and di-ethyl-amine (2 mols.) to stand at the ordinary temperature for several weeks, and then distilling off the alcohol and excess of di-ethyl-amine on the water-bath. When boiled with alcohol it loses  $\text{NH}_3$ , giving a condensation product  $\text{C}_8\text{H}_{18}\text{N}_4$ . The hydrochloride ( $\text{B}^+\text{HCl}$ ) forms glistening transparent prisms, very hygroscopic and easily soluble in alcohol [125°].— $\text{B}^+\text{H}_2\text{Cl}_2\text{PtCl}_4$ ; yellowish-red sparingly soluble prisms [209°] (Pinner, B. 17, 179).

***α*-Di-ethyl-formamidine**

$\text{HC}(\text{NHEt})_2\text{NEt}$ . *Form-ethyl-imid-ethyl-amide*. Formed by the action of an alcoholic solution of ethylamine on the hydrochloride of formimido-ether.

**Salts.**— $\text{B}^+\text{HCl}$ : large deliquescent plates.— $\text{B}^+\text{H}_2\text{Cl}_2\text{PtCl}_4$ : thick red prisms [198°] (Pinner, B. 16, 1649).

**ETHYL-FORMANILIDE** *v.* *FORMIC ACID.*

**DI-ETHYL-FUMARAMIDE** *v.* *Ethylamide of FUMARIC ACID.*

**ETHYL-FURFURINE** *v.* *FURFURINE.*

**TRI-ETHYL-GALLIC ACID** *v.* *GALLIC ACID.*

***β*-ETHYL-GLUTARIC ACID**

$\text{CH}_3\text{CH}_2\text{CH}(\text{CH}_2\text{CO}_2\text{H})_2$ . [67°]. From malonic acid, propionic aldehyde, and glacial acetic acid at 100° (Kommenos, A. 218, 167). The yield is very small (4 p.c. of the malonic acid). Small prisms. V. sol. water, alcohol, ether, or chloroform.

**DI-ETHYL-GLYCIDAMINE**  $\text{C}_8\text{H}_{15}\text{NO}$  *i.e.*

$\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{NEt}_2$ . This constitution is assigned by Reboul (*Bl.* [2] 42, 261) to the substance [160°] formed by the action of di-ethylamine on epichlorhydrin. It is v. sol. water.

*Ethyl-chloride*  $\text{C}_8\text{H}_{15}\text{NOCl}$  *i.e.*

$\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{NEt}_2\text{Cl}$ . Formed from epichlorhydrin and  $\text{NEt}_2$  at 100° (Reboul, *Bl.* [2] 42, 261). Syrup. Moist  $\text{Ag}_2\text{O}$  gives a strongly alkaline syrupy base.— $(\text{C}_8\text{H}_{15}\text{NOCl})_2\text{PtCl}_4$ ; orange needles, v. sol. water, insol. alcohol.

**ETHYL-GLYCOCOLL** *v.* *ETHYL-AMIDO-ACETIC ACID.*

**ETHYL-DI-GLYCOLAMIC ACID** *v.* *ETHYL-IMIDO-DI-ACETIC ACID.*

**ETHYL-GLYCOLLIC ACID** *v.* *Ethyl derivative of GLYCOLLIC ACID.*

**ETHYL-GLYOXALINE**  $\text{C}_8\text{H}_9(\text{C}_2\text{H}_5)_2\text{N}_2$ . [210°]. S.G. 999. Formed by treating tri-bromo-ethyl-glyoxaline with sodium amalgam (Wyss, B. 10, 1373). Prepared by heating glyoxaline with ethyl bromide (Wallach, B. 10, 534). Mobile colourless fluid. Miscible with water.

*Methylo-iodide*  $\text{B}^+\text{MeI}$ : [75°]; large prisms.— $(\text{B}^+\text{MeI})_2\text{CdI}_2$ : [152°]; plates.

*Methylo-chloride*  $\text{B}^+\text{MeCl}$ : formed by the

action of  $\text{AgCl}$  on the *methylo-iodide*.— $(\text{B}^+\text{MeCl})_2\text{PtCl}_4$ : [195°].— $(\text{B}^+\text{MeCl})_2\text{ZnCl}_2$ : transparent soluble crystals [158°].

*Ethyl-bromide*  $\text{C}_8\text{H}_9\text{EtN}_2\text{EtBr}$ . Formed by heating glyoxaline with  $\text{EtBr}$  (Wyss, B. 10, 1367). Syrup.— $(\text{B}^+\text{EtCl})_2\text{PtCl}_4$ : aq: pearly plates.

**Tri-bromo-ethyl-glyoxaline**  $\text{C}_8\text{H}_9(\text{C}_2\text{H}_5)_2\text{N}_2$ . [62°]. Formed by bromination of ethyl-glyoxaline dissolved in dilute  $\text{H}_2\text{SO}_4$  (Wallach, B. 16, 537). Formed also from silver tri-bromo-glyoxaline and  $\text{EtI}$  (Wyss, B. 10, 1372). Colourless crystals. Insol. cold water.

**Para-ethyl-glyoxaline**  $\text{C}_8\text{H}_9(\text{C}_2\text{H}_5)_2\text{N}_2$ . [77°] (W.); [80°] (R.); [268°] (R). Formed by isomeric change from the tertiary ethyl-glyoxaline by passing it through a heated tube (Wallach, B. 16, 543). Prepared by the action of propionic aldehyde-ammonia on glyoxal (Radziszewski, B. 16, 490). Long prisms. Sol. water, alcohol, ether and benzene, sl. sol. ligroin. Secondary base.— $\text{B}^+\text{H}_2\text{Cl}_2\text{PtCl}_4$ : easily soluble prisms or plates. Heated with propyl bromide it gives an ethyl-propyl-glyoxaline which is probably identical with oxal-propylene (W.).

**Para-di-ethyl-glyoxaline**  $\text{C}_8\text{H}_9(\text{C}_2\text{H}_5)_2\text{N}_2$ . *Oxal-ethyl-propylene*. (220°). S.G. 9818. Formed by the action of ethyl bromide on ethyl-glyoxaline (glyoxal-propylene) (Radziszewski, B. 16, 491). Colourless liquid with narcotic smell. Sol. water, alcohol, and ether. The double-zinc-chloride forms crystals melting at [173°].

**ETHYL-GLYOXYLIC ACID**  $\text{C}_8\text{H}_9\text{O}_4$  *i.e.*  $\text{Et.CO.CO}_2\text{H}$ . (74°–78°) at 25 mm. S.G. 1.25.

*Preparation.*—Propionyl cyanide (5 g.) is mixed with  $\text{HCl}$  (2.5 g. of S.G. 1.23) and kept for 2 hours at 0°. More  $\text{HCl}$  (2.5 g. of S.G. 1.23) is added, and, after standing, the mixture is diluted with water and heated for 8 hours on the water-bath. The acid is then extracted with ether (L. Claisen, A. E. Moritz, C. J. 37, 693).

*Properties.*—Liquid with empyreumatic smell. Miscible with water, alcohol, and ether. Sodium amalgam reduces it to *α*-oxy-butyric acid [43°].

**Salts.**— $\text{AgA}'$ : prisms.— $\text{BaA}'$ : aq: m. sol. water.

*Amide*  $\text{Et.CO.CO.NH}_2$ . [117°]. Prepared from propionyl cyanide (2 g.) by mixing with  $\text{HCl}$  (1 g. of S.G. 1.23) and keeping at 0° for 2 hours. The semi-solid product is left for a week over lime. The amide is then separated from  $\text{NH}_4\text{Cl}$  by sublimation (C. A. M.). It may be crystallised from ether.

*Phenyl-hydrazide*  $\text{Et.C}(\text{N}_2\text{HPH})\text{CO}_2\text{H}$  [152°]. Obtained by hydrolysis of the product of the action of diazobenzene chloride on ethyl-aceto-acetic ether (Japp, A. Klingemann, C. J. 53, 519). Yellow silky needles, decomposed on melting. Reduced by sodium amalgam to benzene-*α*-hydrazo-butyric acid  $\text{Ph.NH.NH.CHEt.CO}_2\text{H}$ .

**ETHYL-DIGUANIDE**  $\text{C}_8\text{H}_9\text{N}_6$  *i.e.*  $\text{C}_8\text{H}_9\text{EtN}_6$ .

*Formation.*—By heating di-cyan-di-amide (5 pts.) with  $\text{CuSO}_4$  5aq (7 pts.), ethylamine (8 pts.), and water (32 pts.) for some hours at 100° there is formed the salt  $(\text{C}_8\text{H}_9\text{N}_6)_2\text{CuSO}_4$  5aq, whence  $\text{H}_2\text{S}$  removes the copper, and the resulting  $(\text{C}_8\text{H}_9\text{N}_6)_2\text{H}_2\text{SO}_4$  is then decomposed by baryta (Emich, M. 4, 895).

*Preparation.*—An alcoholic solution of di-

cyandiamide is heated with ethylamine hydrochloride in a sealed tube for several hours (Smolka & Friedreich, *M.* 9, 229).

**Properties.**—Deliquescent crystalline mass, v. sol. water and alcohol, insol. ether.

**Salts.**— $B^+HCl$ : six-sided tables, v. e. sol. water, insol. alcohol and ether.— $B^+H_2Cl_2$ .— $B^+H_2SO_4$ , 1:1 aq: small trimetric crystals,  $a:b:c = 1.04:1.136$ ; v. sol. water, insol. alcohol. [180°], when anhydrous.— $B^+H_2SO_4$ , 1:1 aq. S. 4 in the cold.— $B^+CuSO_4$  aq: minute rose-coloured needles (from cold aqueous solutions).— $B^+CuSO_4$ : crimson crystalline grains (from hot solutions). S. 0.214 in the cold.— $B^+NiSO_4$ , 2 aq.— $Cu(C_2H_5N_2)_2$ : from  $B^+CuSO_4$  by cautious treatment with aqueous NaOH. Red needles, sl. sol. cold water.— $Ni(C_2H_5N_2)_2$ : obtained by boiling  $Ni(OH)_2$  with ethyl-diguanide.—Picates  $B^+C_2H_5(NO_2)_2OH$  and  $B^+2C_2H_5(NO_2)_2OH$  may be crystallised from hot water.

#### $\alpha$ -DI-ETHYL-GUANIDINE

$NH_2C(NEt_2)(NH_2)$ . From cyanamide and diethyl-amine hydrochloride (Erlenmeyer, *B.* 14, 1869). Monoclinic crystals,  $a:b:c = 0.251:1.462$ .  $\beta = 74^\circ 35'$ .  $B^+HCl$ : monoclinic prisms;  $a:b:c = 0.90:1.749$ ;  $\beta = 63^\circ 50'$ .— $B^+H_2PtCl_6$ : orange triclinic tables;  $a:b:c = 0.789:1.564$ ;  $\alpha = 90^\circ 21'$ ;  $\beta = 92^\circ 50'$ ;  $\gamma = 82^\circ 9'$  (Haushofer, *J.* 1881, 330; 1882, 364; *Z.* K. 6, 130; *J.* 267).

$\beta$ -Tri-ethyl-guanidine  $NEt_2C(NEHET)_2$ . Formed by boiling an alcoholic solution of di-ethyl-thio-urea with ethylamine and  $HgO$  (Hofmann, *B.* 2, 601). Strongly alkaline liquid; absorbs  $CO_2$  from the air.— $B^+H_2PtCl_6$ : crystalline plates, v. sol. water.

**ETHYL- $n$ -HEPTYL-OXIDE**  $Et.O.C_2H_{13}$ . (166.6°). S.G.  $\frac{7}{8}$ : 7949. S.V. 220.8. C.E. (0° 10°) 001 (Dobner, A. 243, 5; Cross, A. 189, 5).

Ethyl heptyl oxide  $Et.O.C_2H_{13}$ . (177°). S.G. 1.791. V.D. 5.10 (calc. 4.99). From  $EtI$  and the sodium heptylate from castor oil (Wills, *C.* 6, 812; Petersen, A. 118, 75).

#### **ETHYL-HEXYL-GLYOXALINE** $C_8H_{16}N_2$

**Oxalethyl-cenanthyline.** (271°). S.G. 1.02. 921. From hexyl-glyoxaline and  $EtH$  (Karcz, *M.* 8, 222). Oil.— $B^+H_2PtCl_6$ : yellow soluble plates.

**ETHYL HEXYL OXIDE**  $CH_3Et.CHEt.OEt$ . (132°). S.G. 2.787. From di-chlorinated ether and  $ZnEt_2$  (Lieben, A. 178, 14). With  $HI$  it gives  $EtI$  and secondary hexyl iodide.

#### **ETHYL-HYDANTOIN** $C_5H_8N_2O_2$ , *i.e.*

$CO \langle NEt.CH_2 \rangle$ . Formed by heating ethyl-glycocoll with urea at 125° (Heintz, A. 133, 65). Tables, melting below 100°. V. e. sol. water and alcohol. May be sublimed.

#### **ETHYL-HYDRAZINE** $C_2H_5N_2$ , *i.e.*

$C_2H_5.NH.NH_2$ . (99.5° at 709 mm.). Prepared from  $\beta$ -di-ethyl-urea  $NEHET.CO.NHEt$ , which is treated with nitrous acid and the resulting nitrosamine  $NHEt.CO.NEt.NO$  then reduced by zinc-dust and acetic acid to  $NHEt.CO.NEt.NH_2$ , whence hot conc.  $HCl$  forms  $NH_4Et$ ,  $CO_2$  and  $NHEt.NH_2$ . Ethyl-hydrazine hydrochloride being less soluble than ethylamine hydrochloride may be separated from it by crystallisation (Fischer, A. 199, 281; *B.* 9, 111).

**Properties.**—Colourless mobile liquid of faint ammoniacal odour; very hygroscopic; v. sol.

water, alcohol, ether, and benzene, sl. sol. conc.  $KOH$  aq. It attacks cork and caoutchouc. It fumes in moist air. It gives the carbamide reaction with chloroform and alcoholic potash. Bromine decomposes it, giving off nitrogen. It ppt. metallic oxides from their salts.

**Reactions.**—1. Reduces Fehling's solution in the cold.—2. Reduces  $Ag_2O$ .—3. Reduces  $HgO$  forming  $HgEt_2$ .—4. Reacts with aldehydes with considerable evolution of heat, forming ethyl-hydrazides  $R.CH:N.NHEt$ .—5. Decomposed by nitrous acid gas.—6. Its hydrochloride reacts when heated with potassium cyanate in aqueous solution with production of ethyl semi-carbazide  $NH_2.CO.NH.NHEt$ , which forms very soluble leaflets [105°].—7. Its hydrochloride reacts on phenyl cyanate in dilute ethereal solution, giving rise to leaflets of phenyl-ethyl-semi-carbazide  $NHPh.CO.NH.NHEt$  [111°]; v. sol. alcohol, sl. sol. hot water, decomposed by dilute acids into di-phenyl-urea  $CO_2$  and ethyl-hydrazine.—8. Phenyl thio-carbimide gives phenyl ethyl thio-semi-carbazide  $NHPh.CS.NH.NHEt$  [109°], which crystallises in white leaflets; sl. sol. ether, v. sol. alcohol.—9. Oxalic ether gives grouped needles of  $C_2O_4(NH.NHEt)_2$ , [204°], of which the nitrosamine  $C_2O_4(N(NO).N(NO)Et)_2$ , [114°] crystallises in prisms and gives Liebermann's reaction.—10. Picryl chloride gives  $NHEt.NH.C_6H_3(NO_2)_3$ , [200°], which forms yellowish-red needles; sl. sol. alcohol, sl. hot benzene, and explode on heating.

**Salts.**— $B^+H_2Cl_2$ : needles, v. e. sol. water and alcohol, but the solutions on evaporation leave  $B^+HCl$  as a colourless deliquescent mass. The sulphate forms readily soluble leaflets, the oxalate is a crystalline pp. sol. hot alcohol.

$\alpha$ -Di-ethyl-hydrazine  $C_2H_5N_2$ , *i.e.*  $NEt_2.NH_2$ . (o. 98°). Formed, together with  $NH_3$  and  $NEt_2H$ , by reduction of di-ethyl-nitrosamine  $NEt_2.NO$  with zinc and glacial  $HOAc$ . The bases are converted into hydrochlorides and, on evaporation,  $NH_4Cl$  crystallises first. The filtrate is treated with potassium cyanate and evaporated; when di-ethyl semicarbazide  $NH_2.CO.NH.NEt_2$  separates; and this is decomposed by heating with conc.  $HCl$  for 12 hours at 100° (Fischer, A. 199, 308).

**Properties.**—Colourless, mobile liquid, of faint ammoniacal odour, sol. water, alcohol, and ether; nearly insol. conc.  $KOH$  aq.

**Reactions.**—1. Reduces hot, but not cold, Fehling's solution, being for the most part converted into diethylamine and nitrogen.—2. Mercuric oxide converts it in the cold into tetra-ethyl-tetrazone  $Et_4N_4.N.N.NEt_4$ , a non-volatile oil, sol. alcohol, which is decomposed by heat, is volatile with steam, and reduces ammoniacal  $AgNO_3$ , forming a mirror. Dilute  $HCl$  at 80° splits up tetra-ethyl-tetrazone into aldehyde,  $NEt_2H$ ,  $NEt_2H$ , and nitrogen. The tetrazone forms a platinumchloride  $Et_4N_4.H_2PtCl_6$ , and gives with mercuric chloride a crystalline pp.  $Et_4N_4.HgCl_2$ .—3. Nitrous acid forms  $N_2O$  and diethylamine (or diethyl nitrosamine).—4. Its hydrochloride is converted by potassium cyanide into  $\alpha$ -di-ethyl semicarbazide  $Et_2N.NH.CO.NH_2$ , which forms long prisms [149°], sol. hot water and alcohol, insol. conc.  $KOH$  aq. It forms a crystalline nitrosamine  $Et_2N.N(NO).CO.NH_2$ .

**Salts.**—The hydrochloride, sulphate,

and nitrate are exceedingly sol. water and alcohol. The picrate and platinumchloride  $B_2H_3PtCl_6$  form golden needles.

**Ethyl-iodide**  $NH_2NEtI$ . Needles, v. sol. water and hot alcohol, insol. conc. KOH aq. and ether. Moist  $Ag_2O$  forms a strongly alkaline hydride which is decomposed at a higher temperature into water, ethylene, and di-ethylhydrazine. It may be reduced by zinc and  $H_2SO_4$  to tri-ethylamine.

**ETHYL-HYDRAZINE SULPHONIC ACID**  $EtN_2H_4SO_3H$ .

**Salt**.—KA'. Prepared by heating  $K_2S_2O_8$  with ethylhydrazine at  $90^\circ$ ; the mass obtained being warmed with aqueous  $KHCO_3$  and evaporated below  $70^\circ$  (Fischer, A. 199, 300). Leaflets, sol. water, sl. sol. alcohol. On boiling with strong acids it is decomposed into ethylhydrazine and  $KHSO_4$ . When its aqueous solution is treated with  $HgO$ , even in the cold, it yields potassium diazo-ethane sulphonate  $EtN_2SO_3K$  in the form of glittering needles or leaflets, sol. alcohol. Diazo-ethane sulphonate explodes violently when heated; it may be reduced by zinc dust and acetic acid to the parent ethylhydrazine sulphonate.

**ETHYL-HYDROCARBOSTYRIL** v. OXY-ETHYL-QUINOLINE DITHYDRIDE.

**ETHYL-HYDROXYLAMINE** v. HYDROXYLAMINE.

**ETHYL HYPOCHLORITE**  $C_2H_5OCl$  ( $36^\circ$ ).

**Preparation**.—Chlorine is passed through a cold solution of NaOH (1 pt.) in alcohol (1 pt.) mixed with water (9 pts.) as long as the bubbles are absorbed. The ether rises as an oil to the surface and is washed and dried over  $CaCl_2$  (Sandmeyer, B. 18, 1767; 19, 857).

**Properties**.—Yellow mobile liquid with very irritating smell. It may be distilled. It is very unstable. On superheating its vapour in a tube it explodes violently. The explosion is also brought about in the cold by contact with precipitated copper. Exposed to diffused daylight it begins to decompose after a few hours' boiling violently; in direct sunshine this decomposition begins in a few minutes and ends with an explosion. It mixes without reaction with ether, chloroform, and benzene. Upon aniline, phenol, &c., it acts like  $ClOH$ , oxidising and chlorinating. With HCl, HBr, and HI it at once yields the halogens with liberation of alcohol.

**ETHYL HYPOPHOSPHATE**  $Et_2P_2O_5$ . S.G. 1.117. From  $Ag_3P_2O_5$  and EtI in the cold (Sänger, A. 232, 8). Thick colourless liquid. Heated alone it is decomposed into ethyl phosphate and ethyl phosphite. It is saponified by water.— $EtCaHP_2O_5$  aq. Needles.

**ETHYLIDENE**. The divalent radicle  $CH_2=CH$ . Unlike its isomeric ethylene, it is not known in the free state. By heating ethylidene chloride with sodium at  $190^\circ$  Tollens (A. 187, 811) obtained ethylene, acetylene, ethane, and  $C_2H_4Cl$ .

**ETHYLIDENE DIACETATE** v. Di-acetyl derivative of Ortho-ALDEHYDE, vol. i. p. 106.

**ETHYLIDENE DI-ACETIC ACID** v. METHYL-GLUTARIC ACID.

**ETHYLIDENE-ACETO-ACETIC ETHER** is described under ACETO-ACETIC ACID.

**ETHYLIDENE-DIACETONAMINE** v. ACETONAMINE.

**ETHYLIDENE-DI-ACETONE-ALCAMINE** v. ACETONE-ALCAMINES.

**ETHYLIDENE-DI-ACETONINE** v. ACETONINES.

**ETHYLIDENE ALDEHYDATE** v. ACETAL.

**ETHYLIDENE-m-AMIDO-BENZOIC ACID**  $C_8H_7NO_3$ , i.e.  $CH_2=CH.N(C_6H_4).CO_2H$ . Formed by mixing dilute aqueous solutions of m-amido-benzoic acid and aldehyde (Schiff, A. 210, 117). Amorphous mass, v. e. sol. alcohol and benzene; melts under boiling water. Long boiling with water decomposes it,  $CO_2$  and ethylidene-aniline being among the products. Conc.  $HNO_3$ , containing  $K_2Cr_2O_7$ , gives a transient violet colour.

**ETHYLIDENE-DIAMINE**. Benzoyl derivative  $C_{10}H_{11}N_2O$ , i.e.  $CH_2=CH(NHCO_2C_6H_5)$ . [ $204^\circ$ ] (H. a. S.); [ $188^\circ$ ] (N.). S. (alcohol)  $1.24$  at  $22^\circ$ .

**Formation**.—1. From aldehyde-ammonia and  $BzCl$  (Limpricht, A. 99, 119).—2. By dissolving benzamide in aldehyde to which a few drops of HCl have been added; the reaction being attended with rise of temperature (Nencki, B. 7, 158).—3. By gradually adding benzonitrile (2 mols.) to well-cooled conc.  $H_2SO_4$  containing paraldehyde (1 mol.), leaving the liquid to itself for a few hours, and then ppg. the product by water (Hepp. a. Spiess, B. 9, 1424).

**Properties**.—Long needles (from alcohol), v. sol.  $CHCl_3$ ,  $CS_2$ , ether, and hot alcohol, nearly insol. water. May be sublimed.

**Reactions**.—1. With water at  $130^\circ$  it gives aldehyde and benzamide.—2. Boiled with dilute (10 p.c.)  $H_2SO_4$ , it gives aldehyde,  $NH_3$ , and benzoic acid.

**Tri-ethylidene-diamine** v. ALDEHYDE, Combination 4, vol. i. p. 104.

**ETHYLIDENE-ANILINE**  $C_8H_7N:CH.CH_3$  (?). Aldehyde-anilide. From ethylidene chloride and aniline at  $160^\circ$  (Schiff, B. 3, 416).

**Preparation**.—A mixture of aniline and aldehyde is made at  $-18^\circ$ , then left to itself for some weeks at  $15^\circ$ , and finally heated to  $100^\circ$ . Aniline is removed from the product by dilute  $HOAc$ , and the ethylidene-aniline is separated from ethylidene-di-aniline by alcohol, in which it readily dissolves (Schiff, A. 140, 127; 210, 114). Red resin.— $B'HgCl_2$ .— $B'H_2PtCl_6$ : orange crystalline pp.

Ethylidene-di-aniline ( $C_8H_7NH$ ). $CH.CH_3$ . Prepared as above. Yellow nodules.— $B'H_2Cl.HgCl_2$ .— $B'H_2PtCl_6$ : orange crystalline pp.

**ETHYLIDENE-BIURET**  $C_8H_7N_2O$ , i.e.

$NH \begin{matrix} \diagup CO.NH \\ \diagdown CO.NH \end{matrix} CH.CH_3$ . Trigenic acid. Mol. w.

129. Formed by passing cyanic acid into cold aldehyde (Liebig a. Wöhler, A. 59, 296). Small prisms (from water). Sl. sol. water, almost insol. alcohol. Acid to test papers. Decomposed on dry distillation with formation of ammonia, ammonium carbamate, and an oil, which is in all probability a tri-methyl-pyridine, identical with that obtained by Baeyer and Ador (A. 155, 294). When heated with MeI and alcohol it yields ammonia and methylamine. With NaOBr it evolves only traces of nitrogen. On oxidation with  $HNO_3$ , it is converted into cyanuric acid and carbonic anhydride, a reaction which points to the above formula (Herzig, M. 2, 398).— $AgA$ : pulverulent pp. sol. hot water.

**ETHYLIDENE BROMIDE**  $\text{C}_2\text{H}_4\text{Br}_2$ , i.e.  $\text{CH}_3\text{CHBr}_2$ , *u*-Di-bromo-ethane. (118°). S.G.  $\frac{4}{4}$  2.089 (A.);  $\frac{15}{15}$  2.1029;  $\frac{25}{25}$  2.0854 (Perkin, C. J. 45, 528);  $\frac{30}{30}$  2.055 (Weegmann, Z. P. C. 2, 218).  $\mu_D$  1.5128 (W.). M.M. 9.1.

**Formation.**—1. By brominating ethyl bromide in sunlight (Staedel, B. 11, 1741).—2. From vinyl bromide and HBr (Reboul, C. R. 70, 399).

**Preparation.**—From  $\text{PCl}_5$ ,  $\text{Br}_2$ , and aldehyde in the cold (Paterno a. Pisati, G. 1, 596; Anschütz, A. 235, 801).

**Reactions.**—1. Benzene and  $\text{AlCl}_3$  form ethyl-benzene, *u*-di-phenyl-ethane, and *s*-(4)-di-methyl-anthracene di-hydride.—2. Alcoholic KOAc at 130° gives aldehyde, EtOAc, and acetal (Tavildaroff, A. 176, 12).—3. Alcoholic KHS has no action (difference from ethylene bromide).—4. Ammonia at 130° forms tri-methyl-pyridine (collidine).—5. Water and PbO at 130° give aldehyde.—5. SbCl<sub>3</sub> forms exclusively  $\text{CH}_3\text{CHCl}_2$  (Henry, C. R. 97, 1491).

**ETHYLIDENE BROMO-IODIDE** v. Bromo-iodo-ethane.

**ETHYLIDENE-DI-CARBAMIC ACID.** *Ethyl ether*  $\text{C}_2\text{H}_4\text{N}_2\text{O}_4$  i.e.  $\text{CH}_3\text{CH}(\text{NH.CO}_2\text{Et})_2$ , *Ethylidene-urethane*. [126°]. Formed by the action of aldehyde or acetal on carbamic ether in presence of HCl (Nencki, B. 7, 160; Bischoff, B. 7, 629). Formed also from aldehyde-ammonia and chloro-formic ether in the cold (Schmid, J. pr. [2] 24, 124). Satiny needles; v. sol. ether, alcohol, and hot water. Split up by hot dilute acids into aldehyde and carbamic ether.

**Propyl ether**  $\text{CH}_3\text{CH}(\text{NH.CO}_2\text{C}_2\text{H}_5)_2$ , [116°]. From propyl carbamate, aldehyde, and a little HCl (Bischoff, B. 7, 1082).

**ETHYLIDENE CHLORHYDRIN** v.  $\alpha$ -Chloro-ethyl alcohol.

**ETHYLIDENE CHLORIDE**  $\text{C}_2\text{H}_4\text{Cl}_2$ , i.e.  $\text{CH}_3\text{CHCl}_2$ . Mol. w. 99. (60.1°) (Thorpe, C. J. 37, 186); (58.8°) at 749 mm. (Schiff); (57.3°) (Perkin, C. J. 45, 529); (57.5°) (Bruhl). V.D. 3.42 (for 3.42) (S.). S.G.  $\frac{4}{4}$  1.2039 (T.);  $\frac{25}{25}$  1.1895 (Schiff, A. 230, 96);  $\frac{15}{15}$  1.1845;  $\frac{25}{25}$  1.1712 (P.);  $\frac{30}{30}$  1.1743 (Brühl, A. 203, 11); 1.1750 (Weegmann, Z. P. C. 2, 218). C.E. (0°-10°) .001304; (0°-50°) .0013982 (Thorpe); (9.8 to 56.7) .001438 (Schiff). S.V. 88.96 (Thorpe); 88.56 (Schiff); 89.5 (Ramsey). M.M. 5.835 at 14.4°.  $\mu_D$  1.4168 (W.).  $\mu_D$  = 1.4223.  $R_\infty$  = 84.10 (B.). H.F.p. 34.230 (Th.). H.F.v. 33.070 (Th.). Critical temperature 255° (Paulewsky, B. 16, 2633). By-product in manufacture of chloral (Krämer, B. 3, 257).

**Formation.**—1. By chlorinating ethyl chloride in daylight (Regnault, A. Ch. [2] 71, 355), or in presence of heated animal charcoal (Damoiseau, B. [2] 27, 113).—2. By heating aldehyde with  $\text{PCl}_5$  (Wurtz a. Frapollin, C. R. 47, 418; A. 108, 223; Beilstein, A. 113, 110; Geuther, A. 105, 321). The  $\text{PCl}_5$  is at first kept cool, and the aldehyde added slowly.

**Properties.**—Colourless oil, resembling chloroform in taste and odour.

**Reactions.**—1. Alcoholic potash has no action in the cold, though vinyl chloride is formed on heating.—2. Aqueous  $\text{Na}_2\text{SO}_3$  at 140° gives  $\text{CH}_3\text{CHClSO}_3\text{Na}$  (Kind, Z. [2] 5, 165). Boiling aqueous  $\text{K}_2\text{SO}_3$  gives  $\text{CH}_3\text{CH}(\text{SO}_3\text{K})_2$ , and  $\text{CH}_3\text{CH}(\text{OH})\text{SO}_3\text{K}$  (Staedel, Z. [2] 4, 272).—3.

Sodium at 190° gives hydrogen, acetylene, ethylene, ethane, and vinyl chloride (Tollens, A. 187, 311).—4. Chlorine gives  $\text{CH}_2\text{ClCHCl}_2$  and  $\text{CH}_2\text{CCl}_2$  (Staedel, B. 6, 1403).—5. Bromine in sunlight forms  $\text{CH}_2\text{CBrCl}_2$  (99°),  $\text{CH}_2\text{Br.CBrCl}_2$  (177°), and  $\text{CHBr}_2\text{CBrCl}_2$  (217°) (Staedel, B. 11, 1789).—6. Toluene and  $\text{AlCl}_3$  give *p*-ethyl-toluene, *u*-*p*-di-tolyl-ethane, and *s*-tetra-methyl-anthracene dihydride (Anschütz, A. 235, 314). *m*-Xylene, and  $\text{AlCl}_3$  give (1, 3, 4)-ethyl-*m*-xylene and *u*-di-xylyl-ethane.

**ETHYLIDENE CHLORO - BROMIDE** v. Chloro-bromo-ethane.

**ETHYLIDENE CHLORO-IODIDE** v. Chloro-iodo-ethane.

**ETHYLIDENE CYANURAMIDE** is described under Cyanuramide v. CYANIC ACID.

**ETHYLIDENE-ETHENYL CARBOXYLIC ACID** v. BUTYLENE CARBOXYLIC ACID.

**ETHYLIDENE DI-ETHYL DIOXIDE** is ACETAL (q. v.).

**ETHYLIDENE-DI-ETHYL-DI-SULPHONE**  $\text{CH}_3\text{CH}(\text{SO}_2\text{Et})_2$ , [75°-78°]. Prepared by treating  $\text{CH}_3\text{C}(\text{SEt})_2\text{CO}_2\text{H}$  (obtained from pyruvic acid and mercaptan) with  $\text{KMnO}_4$  (Escalaes a. Baumann, B. 19, 2814). Plates; sl. sol. water, m. sol. alcohol and ether. Evolves hydrogen when sodium is added to its solution in dry ether or benzene, the resulting salt is too unstable to purify (E. Fromm, B. 21, 187). Its bromo-derivative  $\text{CH}_3\text{CBr}(\text{SO}_2\text{Et})_2$ , [115°] crystallises in small sparingly soluble prisms which are reconverted by boiling KOHAq into the original  $\text{CH}_3\text{CH}(\text{SO}_2\text{Et})_2$ .

**ETHYLIDENE IODIDE**  $\text{CH}_3\text{CHI}_2$ , (c. 178°). S.G.  $\frac{4}{4}$  2.84.

**Formation.**—1. From ethylidene chloride and  $\text{AlI}_3$  in  $\text{CS}_2$  (Gustavson, B. 7, 731).—2. From  $\text{CH}_3\text{CHCl}_2$  and  $\text{CaI}_2$  3½aq at 100° (Spindler, A. 231, 267).—3. From acetylene and HI (Berthelot, A. 132, 122).

**Properties.**—Liquid. Converted by alcoholic KOH into vinyl iodide.

**ETHYLIDENE-LACTAMIC ACID** v.  $\alpha$ -Imido-di-propionic acid.

**ETHYLIDENE-LACTIC ACID** v. LACTIC ACID.

**ETHYLIDENE-MALONIC ACID**

$\text{CH}_3\text{CH}:\text{C}(\text{CO}_2\text{H})_2$ , *Ethyl ether* Et<sub>2</sub>A'. (115°-118°) at 17 mm. S.G.  $\frac{15}{15}$  1.0435. From malonic ether (1 mol.), aldehyde (2 mols.), and  $\text{Ac}_2\text{O}$  (1½ mols.) at 100° (Kommenos, A. 218, 157). (The yield is 54 p.c. of the malonic ether.) Liquid, smelling something like camphor. Aqueous baryta forms various salts, including an easily soluble one, which is possibly a salt of oxethyl-malonic acid,  $\text{CH}_3\text{CH}(\text{OH})\text{CH}(\text{CO}_2\text{H})_2$ . KOH and dilute alcohol gives  $\beta$ -methyl-glutaric acid.

**Ethylidene-di-malonic ether**

$\text{CH}_3\text{CH}(\text{CH}(\text{CO}_2\text{Et})_2)_2$ , (209°-212°) at 20 mm. A by-product in the preparation of ethylidene-malonic ether. (The yield is 8 p.c. of the malonic ether; Komnenos, A. 218, 158). It is formed by the action of ethylidene-malonic ether upon malonic ether:  $\text{CH}_3\text{CH}:\text{C}(\text{CO}_2\text{Et})_2 + \text{CH}_2(\text{CO}_2\text{Et})_2 = \text{CH}_3\text{CH}(\text{CH}(\text{CO}_2\text{Et})_2)_2$ . Dilute alcoholic KOH converts it into  $\beta$ -methyl-glutaric acid.

**ETHYLIDENE-MELAMINE** described under *Ethylidene-cyanuramide* v. CYANIC ACIDS.

**ETHYLIDENE-METHYL-KETOLE** v. Di-methyl-ethylidene-di-indole.

K K

**ETHYLIDENE-DI-( $\beta$ )-NAPHTHYL-OXIDE**

$\text{CH}_3\text{CH} \begin{smallmatrix} \text{C}_{10}\text{H}_7 \\ \text{C}_{10}\text{H}_7 \end{smallmatrix} \text{O}$ . Anhydride of di-oxy-di-naphthyl-ethane. [178°]. Crystalline solid. Insol. alkalis. Formed by heating a solution of ( $\beta$ )-naphthol and aldehyde in acetic acid with HCl or  $\text{H}_2\text{SO}_4$ , or by the same treatment of the previously formed di-( $\beta$ )-naphthyl orthaldehyde  $\text{CH}_3\text{CH}(\text{O.C}_{10}\text{H}_7)_2$  (Claisen, *B.* 19, 3318; *A.* 237, 270; cf. vol. i. p. 105).

**ETHYLIDENE-DIOXAMIDE**  $\text{C}_8\text{H}_{10}\text{N}_2\text{O}_4$  i.e.  $(\text{NH}_2\text{CO.CO.NH})_2\text{CH.CH}_3$ . A pulverulent pp. formed when cyanogen is passed into crude aldehyde (Berthelot a. Péan de St. Gilles, *A.* 128, 338; cf. Schiff, *A.* 151, 211).

**ETHYLIDENE OXY-CHLORIDE** v. Di-chloro-di-ethyl oxide.

**ETHYLIDENE-DI-PHENOL** v. Di-oxy-di-phenyl-ethane.

**ETHYLIDENE-METAPYRAZOLONE** v. Di-oxy-ethylidene-pyrazole.

**ETHYLIDENE SULPHIDE** v. Thio-acetic aldehyde.

Di-ethylidene-tetra-sulphide

$\text{CH}_3\text{CH} \begin{smallmatrix} \text{S.S} \\ \text{S.S} \end{smallmatrix} \text{CH.CH}_3$ . Formed by oxidation of thialdine by adding to the solution strongly acidified with HCl a weak solution of iodine in KI. Amorphous pp. (Fasbender, *B.* 20, 463).

**ETHYLIDENE-THIO-UREA**  $\text{C}_4\text{H}_6\text{N}_2\text{S}$  i.e.

$\text{CS} \begin{smallmatrix} \text{NH} \\ \text{NH} \end{smallmatrix} \text{CHMe}$ . From aldehyde and thio-urea at 100° (Emerson Reynolds, *C. N.* 24, 87). Granules, insol. cold water, m. sol. hot alcohol, sl. sol. ether. Boiling water splits it up into aldehyde and thio-urea.

Di-ethylidene-thio-urea. Ammonia compound  $(\text{CH}_3\text{CH})_2\text{N.CSNH}_2$ . [180°]. Formed by heating a moderately concentrated solution of thio-urea with aldehyde-ammonia (Noncki, *B.* 7, 158). Needles; sl. sol. boiling water, insol. cold alcohol and ether. Its aqueous solution, which is intensely bitter, is resolved by prolonged boiling, or more quickly in presence of acids, into aldehyde, thio-urea, and  $\text{NH}_3$ .

**ETHYLIDENE-TOLUIDINE**

$\text{CH}_3\text{CH:N.C}_6\text{H}_4\text{Me}$ ? Aldehyde-toluide. Yellow nodules, formed by treating toluidine with aldehyde. Its salts are resinous (Schiff, *Z.* 1865, 400).

**ETHYLIDENE-UREA**  $\text{C}_4\text{H}_6\text{N}_2\text{O}$  i.e.

$\text{CO} \begin{smallmatrix} \text{NH} \\ \text{NH} \end{smallmatrix} \text{CH.CH}_3$ . [164°]. Formed by the action of an alcoholic solution of aldehyde on urea in the cold (Schiff, *A.* 151, 204). Small needles; v. sl. sol. water and ether, sl. sol. alcohol. Decomposed by heat into  $\text{NH}_3$ , melanurenic acid, and oxy-trialdine  $\text{C}_4\text{H}_{11}\text{NO}$ . Rapidly decomposed by pure  $\text{HNO}_3$  with evolution of  $\text{CO}_2$  and  $\text{N}_2\text{O}$  in equal volumes, together with a little nitrogen (Franchimont, *R. T. C.* 6, 221).

**ETHYLIDENE URETHANE** v. Ethylidene-di-carbamic acid.

**ETHYLIMIDO-DI-ACETIC ACID**  $\text{C}_8\text{H}_{10}\text{NO}_4$  i.e.  $\text{NEt}(\text{CH}_2\text{CO}_2\text{H})_2$ . Ethyl-di-glycolamic acid. From ethylamine and chloro-acetic acid (Heintz, *A.* 132, 1; 145, 229). Short trimetric prisms, v. sol. water, sl. sol. alcohol.— $\text{CuA}^+$ : minute blue dimetric tables, sl. sol. water.

Ethyl ether  $\text{Et}_2\text{A}^+$ . (a. 210°). Oil.

**ETHYLIMIDO-DI-PHENYLENE SULPHIDE**  $\text{S}(\text{C}_6\text{H}_5)_2\text{NEt}$ . Ethyl-thio-diphenylamine. [102°]. From imido-diphenylene sulphide and  $\text{EtBr}$  (Bernthsen, *A.* 280, 98). Prisms.  $\text{FeCl}_3$  colours its alcoholic solution pale brown.

**TRI-ETHYLIN** v. Tri-ethyl derivative of GLYCERIN.

**ETHYL-INDAZINE**  $\text{C}_8\text{H}_{10}\text{N}$  i.e.

$\text{C}_6\text{H}_5 \begin{smallmatrix} \text{CH} \\ \text{N} \end{smallmatrix} \text{NC}_2\text{H}_5$ . Formed by heating indas-

ine with  $\text{EtI}$  for four hours at 100°, saturating with  $\text{NaOH}$ , and extracting with ether (Fischer a. Tafel, *A.* 227, 303). Brown liquid, smelling like indazine; more sol. water than indazine. Is a tertiary base.— $\text{B}^+\text{H}_2\text{SO}_4$ .

Bromo-ethyl- $\psi$ -indazine  $\text{C}_8\text{H}_8\text{N}_2\text{Br}$ . [48°]. Obtained as a sublimate by heating bromo-ethyl- $\psi$ -indazine carboxylic acid,  $\text{CO}_2$  being evolved (F. a. T.). V. sl. sol. water, v. sol. alcohol, ether, and chloroform. It shows no basic properties.

**ETHYL- $\psi$ -INDAZYL-ACETIC ACID**

$\text{C}_{11}\text{H}_{12}\text{N}_2\text{O}_3$  i.e.  $\text{C}_6\text{H}_5 \begin{smallmatrix} \text{C}(\text{CH}_2\text{CO}_2\text{H}) \\ \text{N} \end{smallmatrix} \text{N}$ . [131°].

Formed by atmospheric oxidation of ethyl-hydrazido-cinnamic acid which is obtained from the nitrosamine of ethyl-o-amido-cinnamic acid  $\text{NO.NEt.C}_6\text{H}_4\text{CH:CH.CO}_2\text{H}$  by reduction with zinc-dust and acetic acid (Fischer a. Kuzel, *B.* 16, 654; Fischer a. Tafel, *A.* 227, 803). Colourless plates, sol. alcohol, ether, and aqueous alkalis, sl. sol. water. At 100° it splits off  $\text{CO}_2$ , forming methyl-ethyl- $\psi$ -indazine. It forms salts both with acids and with bases. It does not reduce Fehling's solution or  $\text{HgO}$ .

Bromo-ethyl- $\psi$ -indazyl-acetic acid

$\text{C}_{11}\text{H}_{11}\text{N}_2\text{O}_3\text{Br}$ . [173°]. Formed from the preceding by treatment with  $\text{Br}$  (65 pts.) in  $\text{HOAc}$  (Fischer a. Kuzel, *A.* 221, 288). Needles, grouped in fans, v. sol. alcohol and ether, almost insol. water. Oxidation with  $\text{K}_2\text{Cr}_2\text{O}_7$  and  $\text{H}_2\text{SO}_4$  forms bromo-ethyl- $\psi$ -indazine carboxylic aldehyde  $\text{C}_{11}\text{H}_9\text{N}_2\text{OBr}$  [88°] and, by further oxidation, bromo-ethyl- $\psi$ -indazine carboxylic acid  $\text{C}_{11}\text{H}_9\text{N}_2\text{O}_3\text{Br}$  [210°], which crystallises in needles (from  $\text{MeOH}$ ).

Di-bromo-ethyl- $\psi$ -indazyl-acetic acid

$\text{C}_{11}\text{H}_{10}\text{Br}_2\text{N}_2\text{O}_3$ . [196°]. From the acid (1 pt.) and  $\text{Br}$  (1.7 pts.) in  $\text{HOAc}$  (5 pts.) in the cold. Stellate groups of needles; almost insol. water, sl. sol. alcohol, ether, and chloroform. Reconverted into the parent acid by sodium amalgam.

**DI-ETHYL-INDIGO**  $\text{C}_{20}\text{H}_{18}\text{O}_2\text{N}_2$  i.e.

$\text{C}_6\text{H}_5\text{C}_2\text{O}_2\text{N}_2\text{Et}_2\text{C}_6\text{H}_5$ . Prepared by reducing the di-ethyl-derivative of pseudo-isatin- $\alpha$ -oxim  $\text{C}_6\text{H}_5 \begin{smallmatrix} \text{CO} \\ \text{N} \end{smallmatrix} \text{C}(\text{NOEt})$  with alcoholic ammonium sulphide, and then passing a stream of  $\text{CO}$ , through the solution (Bayer, *B.* 16, 2201). Blue felted needles. V. sol. alcohol, forming a deep-blue solution, the spectrum of which closely resembles that of indigo. In ether, acetone, chloroform,  $\text{CS}_2$ , and aniline it is less soluble. It sublimes as a purple vapour, condensing to blue prisms. It dissolves in strong  $\text{H}_2\text{SO}_4$  with a greenish-blue colour, and on heating is sulphated. With zinc-dust and alkalis it is reduced, and the solution then dyes like indigo. On oxidation it gives ethyl-pseudo-isatin. By weak

reduction the di-ethyl-derivative of pseudo-isatin-*o*-oxim is formed.

**ETHYL-INDOLE**  $C_{10}H_{11}N$  i.e.

$C_6H_5 \begin{array}{c} \diagup CH \\ | N \\ \diagdown CH \\ | C_2H_5 \end{array}$  (about 247°). Obtained by heating at 185°-190° the carboxylic acid [183°] which is formed by the action of HCl on phenyl-ethyl-hydrazine-pyruvic acid (Fischer a. Hess, *B.* 17, 566). Liquid. The HCl solution gives a violet colour to a pine-wood shaving. By a cold alkaline solution of chlorine, followed by hot alcoholic NaOH, it is converted into ethyl-pseudo-isatin. The picrate forms red needles.

**Ethyl-indole?**  $C_6H_5 \begin{array}{c} \diagup C \\ | NH \\ \diagdown CH \\ | C_2H_5 \end{array}$  (283°

cor.). Formed by heating aniline (30 g.) with  $ZnCl_2$  (50 g.), lactic acid (35 g.), and sand to prevent frothing (Pictet a. Duparc, *B.* 20, 3415). Yellow oil without basic character, v. sl. sol. water, v. sol. alcohol, ether, benzene, and  $CHCl_3$ . May be distilled with steam. Colours pinewood moistened with HCl red. Bromine added to its solution in chloroform gives an intense violet colour. The picrate melts at [143°].

**ETHYL-INDOLE-CARBOXYLIC ACID**

$C_{11}H_{11}NO_2$  i.e.  $C_6H_5 \begin{array}{c} \diagup C \\ | C=O \\ | NH \\ \diagdown CH \\ | C_2H_5 \end{array}$  [183°]. Formed

by the action of hot aqueous HCl on phenyl-ethyl-hydrazine-pyruvic acid (for theory of reaction v. under INDOLE derivatives) (Fischer a. Hess, *B.* 17, 565). Colourless needles. V. sol. alcohol, ether, benzene, and chloroform, less sol. water. Heated to its melting-point for some time it loses  $CO_2$ , giving ethyl-indole. A cold alkaline solution of chlorine, followed by alcoholic NaOH, converts it into ethyl-pseudo-isatin.

**ETHYL-INDOXYL** v. INDOXYL.

**ETHYL-INDOXYLIC ACID** v. INDOXYLIC ACID.

**ETHYL-DI-IODAMINE** v. ETHYLAMINE.

**ETHYL IODIDE**  $C_2H_5I$ . Mol. w. 156. (72°) (Schiff); (72-4°) (Perkin, *C.* J. 45, 460). S.G.  $\frac{15}{15}$  1.9433;  $\frac{25}{25}$  1.9243 (P.);  $\frac{30}{30}$  1.9795 (Dobrinier, *A.* 243, 24). C.E. (0°-10°) 0.0116 (D.). S.V. 86.12 (S.); 85.6 (D.). V.D. 5.48 (calc. 5.41). M.M. 10.075 at 18.1° (P.). H.F.p. 5.660 (Iodine solid); 11.090 (I gaseous) (*Th.*); 7.000 (I gaseous, EtI gaseous) (Berthelot); 12.700 (I solid, EtI liquid) (B.). H.F.v. 4.790 (I solid); 9.930 (I gaseous) (*Th.*). Formed by distilling alcohol with HI containing free I, or by the action of P and I on alcohol (Gay-Lussac, *A. Ch.* 91, 89; Serullas, *A. Ch.* [2] 25, 323; 42, 119; Marchand, *J. pr.* 33, 186; Frankland, *C. J.* 2, 263; 3, 322; Lautemann, *A.* 113, 241; Hofmann, *C. J.* 13, 69; De Vrij, *J. Ph.* [3] 31, 169; Paterno, *G.* 4, 149; H. Schiff, *B.* 7, 592; Personne, *C. R.* 52, 468). The rate at which HI etherifies alcohol has been studied by Villiers (*C. R.* 90, 1563; 91, 62).

**Preparation.**—1. Amorphous phosphorus (10 pts.), alcohol (50 pts. of 90 p.c.), and iodine (100 pts.), are mixed and left to themselves for 24 hours; the mixture is then distilled (Rieth a. Beilstein, *A.* 126, 250).—2. An alcoholic solution of iodine is slowly run into a retort containing alcohol and clear phosphorus (Hofmann).

**Properties.**—Colourless liquid. Not very inflammable. When not quite pure it turns brown in light. Conc.  $HNO_3$  liberates iodine. Aqueous

KOH has little action. When a soluble salt of silver is added to an alcoholic solution of EtI silver iodide is ppd.

**Reactions.**—1. Passage through a red-hot tube gives hydrogen, ethylene, and ethylene iodide (E. Kopp, *J. Pharm.* [3] 6, 109).—2. Mercury forms  $EtHgI$ .—3. Heating with  $ZnEt_2$  in ethereal solution at 170° gives butane, together with a little ethylene and ethane (Brodie, *C. J.* 3, 405).—4. Sodium ethide gives ethylene and ethane in the cold.—5. Tin at 180° gives  $SnEt_2I_2$  (Frankland, *C. J.* 6, 57).—6. Silver powder at 120° gives butane (Wislicenus, *Z.* [2] 4, 681).—7. By heating in sealed tubes with excess of *sinc* there is formed zinc ethide; when excess of EtI is used the product is butane.—8. The copper *sinc* couple at 100° forms  $IZnEt$ . In presence of water or alcohol ethane is evolved (Gladstone a. Tribe, *C. J.* 26, 415).—9. Alcoholic ammonia forms iodides of ammonium and of mono-, di-, tri-, and tetra-ethyl-ammonium.—10. When saturated with  $PH_3$  and heated, either alone or with  $ZnO$ , there is formed tri- and tetra-ethyl-phosphonium iodide (Hofmann, *B.* 4, 372).—11. Chromic acid mixture gives iodine and acetic acid.—12. Chlorine gives  $EtCl$  and I (Dumas a. Stas, *A.* 35, 162).—13. Bromine gives  $EtBr$  and I (Friedel, *C. R.* 60, 346).—14.  $ICl$  gives  $EtCl$  and I (Geuther, *A.* 123, 123).—15. HI at 150° forms some ethane (Butlerow, *A.* 144, 36).—16. Heating with  $HgCl_2$  gives  $EtCl$  (Oppenheim, *C. R.* 62, 1085).—17. Heating with  $K_2SO_4$  gives potassium ethane sulphonate  $EtSO_3K$  (Strecker, *Z.* [2] 4, 213).—18. Sodium amalgam acting on a moist mixture of EtI with  $CS_2$  forms  $Et_2CS_2$  (Nasini a. Seala, *G.* 17, 236; cf. Löwig a. Scholz, *J. pr.* 79, 441).—19. Water at 150° gives ether (Reynoso, *A. Ch.* [3] 48, 385).

**ETHYL-ISATIN**  $C_{10}H_9NO_2$ . [137°]. Long red needles (Pancksch, *B.* 17, 2805). Formed by heating with  $HClAq$  the product of the action of di-chloro-acetic acid on *p*-amido-phenyl-ethane  $C_6H_4Et(NH_2)[1:4]$ .

**Ethyl-pseudo-isatin**  $C_6H_5 \begin{array}{c} \diagup CO \\ | NEt \\ \diagdown CO \end{array}$ . *Lao-tam* of ethyl isatic acid. [95°].

**Formation.**—1. By the action of a cold alkaline solution of chlorine followed by hot alcoholic NaOH on ethyl-indole-carboxylic acid [183°], which is obtained by the action of HCl on phenyl-ethyl-hydrazine-pyruvic acid (Fischer a. Hess, *B.* 17, 566).—2. By reduction\* of the di-ethyl-derivative of pseudo-isatin-*o*-oxim

$C_6H_5 \begin{array}{c} \diagup CO \\ | NEt \\ \diagdown C(NOEt) \end{array}$  with zinc-dust and oxidation of the product with  $FeCl_3$  (Baeyer, *B.* 16, 2193).

**Properties.**—Large red plates. Soluble in hot water, alcohol and ether. With thiophene and  $H_2SO_4$  it gives a blue colouring-matter soluble in ether. It dissolves in alkalis with a yellow colour at once forming a salt of ethyl-isatic acid

$C_6H_5 \begin{array}{c} \diagup CO.CO_2H \\ | NHEt \end{array}$

**Ethyl-pseudo-isatin-*o*-oxim**

$C_6H_5 \begin{array}{c} \diagup C(NO)H \\ | NEt \\ \diagdown CO \end{array}$ . [162°]. Yellow four-sided prisms. Formed by the action of hydroxylamine on ethyl-pseudo-isatin. On reduction with zinc-dust followed by oxidation with  $FeCl_3$  it yields ethyl-pseudo-isatin. It does not yield indigo on

treatment with ammonium sulphide (Baeyer, *B.* 16, 2196).

**Ethyl-pseudo-isatin- $\alpha$ -ethylloxim v. Di-ethyl-derivative of pseudo-isatin- $\alpha$ -oxim.**

**ETHYL-KAIRINE v. Ethyl ether of (B. 4)-Oxy-(Py. 4)-ETHYL-QUINOLINE TETRAHYDRIDE.**

**DI-ETHYL-KETINE v. DI-METHYL-DI-ETHYL PYRAZINE.**

**DI-ETHYL-KETONE**  $C_8H_{10}O$  i.e. Et.CO.Et. *Propione. Metacetone.* Mol. w. 86. (101°). S.G. 2.829;  $d_4^{20}$  0.815. S. 4.2. H.C. 735,971 (Lougouine, *Bl.* [2] 41, 889). A product of the distillation of sugar, starch, or mannite with lime (Fremy).

**Formation.**—1. By the dry distillation of barium propionate (R. Morley, *A.* 78, 187).—2. By the action of ZnEt. on propionyl chloride (Freund & Pebal, *A.* 118, 9).—3. From sodium ethide and CO (Wanklyn, *A.* 140, 211).—4. By oxidising oxy-hexoic acid (di-eth-oxalic acid) with  $K_2Cr_2O_7$  and  $H_2SO_4$  (Chapman & Smith, *C. J.* 20, 173); or by heating the ether of the same acid for several hours with fuming HCl at 150° (Geuther, *Z.* 1867, 709).—5. By oxidation of di-ethyl-carbinol Et<sub>2</sub>CH(OH) (Wagner & Saytzeff, *A.* 179, 322).—6. By the action of dry FeCl<sub>3</sub> on propionyl chloride (Hamonet, *Bl.* [2] 50, 547).

**Properties.**—Mobile oil, lighter than water, v. sol. alcohol and ether. Smells like acetone. Slowly combines with  $KHSO_4$  on long agitation (Schramm, *B.* 16, 1583). Chromic acid mixture oxidises it to propionic, acetic, and carbonic acids. Reduced by sodium in presence of water to di-ethyl-carbinol and the pinacone  $C_8H_{16}(OH)_2$ . Treated with di-methyl-aniline and ZnCl<sub>2</sub> there is formed tetra-methyl-di-amido-di-phenyl-methane (Döbner & Petschhoff, *A.* 242, 333). Treatment with Zn, EtI, and then with water gives tri-ethyl-carbinol (A. Saytzeff, *J. pr.* [2] 81, 320).

**Cyanhydrin** Et<sub>2</sub>C(OH).CN.  *$\alpha$ -Oxy-hexonitrile.* From the ketone and dilute HCN (Tiemann & Köpfer, *B.* 14, 1978). Liquid, lighter than water.

**Oxim** Et<sub>2</sub>C.NOH. (163°) at 726 mm. From di-ethyl-ketone and an alcoholic solution of hydroxylamine (Scholl, *B.* 21, 509). Oil, insol. water, sol. alcohol and ether. When dissolved in ether and treated with  $N_2O$ , it gives amyl-pseudo-nitrole Et<sub>2</sub>C(NO).NO<sub>2</sub> in the form of large tables [63°], which forms blue solutions in ether and chloroform.

**DI-ETHYL-KETONE DI-CARBOXYLIC ACID**  $C_8H_{10}O_4$  i.e. CO(CH<sub>2</sub>.CH<sub>2</sub>.CO<sub>2</sub>H)<sub>2</sub>. [138°] and [c. 110°]. Formed by saponifying its ether. Thin plates, decomposed on distillation. Not reduced by sodium-amalgam. Does not combine with Br.  $HNO_3$  oxidises it to succinic acid.—Ag<sub>2</sub>A<sup>+</sup>: minute needles.

**Mono-ethyl ether** EtHA<sup>+</sup>. [68°]. From Et<sub>2</sub>A<sup>+</sup> (1 mol.) and alcoholic KOH (1 mol.). Needles, insol. ligroin, sol. water, alcohol, ether, and chloroform.—AgEtA<sup>+</sup>.

**Di-ethyl ether** Et<sub>2</sub>A<sup>+</sup>. (286°). Formed by heating furfuryl-acrylic acid with alcohol saturated with HCl (Marekwald, *B.* 20, 2811; 21, 1898). Heavy oil. Alcoholic NH<sub>3</sub> forms  $C_8H_{10}O.N_2$  [292°].

**Oxim of the di-ethyl ether** HO.N:C(CH<sub>2</sub>.CH<sub>2</sub>.CO<sub>2</sub>Et)<sub>2</sub>. [38°]. Slender needles, al. sol. water.

#### Phenyl-hydrazide

$N_2HPh.C(C_2H_5.CO_2H)_2$ . [114.5°]. Minute pale yellow crystals, insol. water, benzene, and light petroleum, sol. alcohol and ether. Heating at 210° with HIAq (S.G. 1-7) and amorphous phosphorus reduces it to *n*-pinelic acid.

**Phenyl-hydrazide of the mono-ethyl ether**  $N_2HPh.C(C_2H_5.CO_2H)(C_2H_5.CO_2Et)$ . [112°]. Minute pale yellow crystals, insol. water and light petroleum, v. sol. hot alcohol and ether.

**TETRA-ETHYL LEUCANILINE v. Tetra-ETHYL-TRI-*p*-AMIDO-TRI-PHENYL-METHANE.**

**ETHYL-LEUCAZONE v. AZAULCOIC ACID.**

**DI-ETHYL-MALEIC ACID**  $C_8H_8O_4$  i.e. CO<sub>2</sub>H.CEt.CEt.CO<sub>2</sub>H. *Xeronic acid.* The anhydride occurs among the products of the distillation of citric acid, being formed by boiling citraconic anhydride for a long time. This anhydride is converted into the Ca salt by digestion with water and CaCO<sub>3</sub> (Fittig, *A.* 188, 59). Formed also by treating *aa*-di-bromo-butyric acid with reduced silver (Otto & Beckurts, *A.* 239, 277). The free acid, liberated by adding HCl to its salts, changes at once into the anhydride. It does not combine with Br. HI reduces it to di-ethyl-succinic acid. Chromic acid mixture oxidises it to propionic acid (Rosser, *B.* 15, 1321).

**Salts.**—Ag<sub>2</sub>A<sup>+</sup>.—CuA<sup>+</sup> aq.—CaA<sup>+</sup> aq.—BaA<sup>+</sup> aq.

**Anhydride**  $C_8H_6O_4$ . (242° i.v.). Liquid; volatile with steam. Sl. sol. cold water.

**ETHYL-MALONIC ACID**  $C_8H_8O_4$  i.e. CHEt(CO<sub>2</sub>H)<sub>2</sub>. Mol. w. 132. [122°].

**Formation.**—1. By treating *a*-bromo-*n*-butyric acid with KCy and boiling the product with potash (Wislicenus, *A.* 149, 220; 165, 93; Tupoleff, *A.* 171, 243; Markownikoff, *A.* 182, 324). 2. By heating malonic ether (16 pts.), and sodium (2 pts.) dissolved in alcohol (25 pts.) with gradual addition of EtI (20 pts.). The resulting ether is saponified by potash, neutralised by HCl, and converted into the Ca salt. The Ca salt is then decomposed by HCl and the acid extracted with ether (Conrad, *A.* 204, 134).

**Properties.**—Short four-sided prisms or feathery groups. V. sol. water, alcohol, and ether. At 160° it splits up into CO<sub>2</sub> and butyric acid. The same decomposition occurs when its aqueous solution is evaporated at too high a temperature, especially in presence of mineral acids. Fe<sub>2</sub>Cl<sub>3</sub> gives no pp. in neutral solutions.

**Salts.**—K<sub>2</sub>A<sup>+</sup> aq.: small crystals, v. sol. water, insol. alcohol.—Na<sub>2</sub>A<sup>+</sup> aq.: efflorescent granular mass.—BaA<sup>+</sup>: small needles.—CaA<sup>+</sup> aq.: prisms; sl. sol. hot, v. sol. cold, water.—ZnA<sup>+</sup> 2aq.: crystalline powder composed of minute six-sided plates; S. 22.—ZnA<sup>+</sup> 8aq.—CuA<sup>+</sup> 3aq.: bluish-green tablets.—PbA<sup>+</sup>: white pp. becoming granular on boiling.—Ag<sub>2</sub>A<sup>+</sup>: sparingly soluble needles.—The aniline salt when treated in benzene with phosphorus pentachloride gives PhN:CH.O.COEt.CONHPh [104°], (Py. 1)-chloro-(Py. 3)-oxy-(Py. 2)-ethyl-quinoline [248°], and the anilide of di-chloro-butyric acid [200°] (Rügheimer & Schramm, *B.* 21, 804).—The *o*-toluidine salt gives with PCl<sub>5</sub> (Py. 1)-chloro-(Py. 3)-oxy-(Py. 2)-ethyl-(B. 4)-methyl-quinoline (R. & S.) [225°].

**Di-ethyl ether** Et<sub>2</sub>A<sup>+</sup>. (200° uncor.); (210° cor.). S.G.  $\frac{1}{4}$  1.0124;  $\frac{3}{4}$  1.0044. M.M. 9.272 at 15.5° (Perkin, *C. J.* 45, 513). From

the silver salt and EtI. Prepared also by the action of EtI (1 mol.) on a mixture of malonic ether (1 mol.) and NaOEt (1 mol.) (Conrad, *B.* 12, 751; *A.* 204, 184). Formed also by heating malonic ether with EtI and zinc (Schukoffsky, *J. R.* 1887, 601). Above 250° it is partially decomposed with formation of butyric ether. Iodine appears to convert sodium ethyl-malonic ether into  $C_2H_5Cl(CO_2Et)_2$ , whence alcoholic KOH forms  $Et_2C(OEt)(CO_2K)$ , while baryta-water forms barium ethyl-tartronate (Bischoff & Hausdörfer, *A.* 239, 120).

*Amide*  $CH_2Et(CONH_2)_2$ . [208°]. From the ether and  $NH_3$  (Freund & Goldsmith, *B.* 21, 1243).

*Amide-anilide*  $CH_2Et(CONH_2)(CONHPh)$ . [182°]. Formed by heating the amide (1 mol.) with aniline (1 mol.).

*Anilide*  $CH_2Et(CONHPh)_2$ . [215°] (F. a. G.); [223°] (Rüchheimer, *B.* 17, 235). Needles (from alcohol). Formed by heating the amide (1 mol.), the acid, or the ether, with aniline (2 mols.).

*Mono-anilide*  $CH_2Et(CONHPh)(CO_2H)$ . [150°]. Formed by boiling the preceding with excess of lime (F. a. G.).

*Phenylhydrazide*  $CH_2Et(CO.NH.NHPh)_2$ . [233°]. Obtained by heating the amide with phenyl-hydrazine (F. a. G.). Needles (from HOAc); insol. water, sl. sol. alcohol.  $COCl_2$  converts it into  $C_6H_5N_2O$ , [above 300°].

*Di-ethyl-malonic acid*  $C_4H_6O_5$ , i.e.  $CEt_2(CO_2H)_2$ . [121°]. S. 65 at 16°. Formed by treating malonic ether with NaOEt (2 mols.) and EtI (2 mols.), and saponifying the product (Conrad, *A.* 204, 138). Prisms; v. sol. alcohol and ether. At 170° it splits up into  $CO_2$  and  $CH_2Et_2CO_2H$ .

*Salts*.— $CaA''$ : moderately soluble crystalline pp.— $AgA''$ : crystalline pp.

*Ethylether*  $Et.A''$ . (239° cor.). S.G. 1.19917;  $d_4^{20}$  0.844. M.M. 11.20 at 19° (Perkin, *C. J.* 45, 513). Formed as above. Formed also by treating malonic ether with ZnEt<sub>2</sub> (Martino & Schukoffsky, *J. R.* 1887, 297).

*References*.—CHLORO- and BROMO- ETHYL-MALONIC ACID and ETHER.

**ETHYL-MALONYL-UREA** v. *Ethyl-derivative of BARBITURIC ACID*.

(a) **ETHYL-NAPHTHALENE**  $C_{12}H_{12}$ , i.e.  $C_{10}H_7.C_2H_5$ . (259° i.v.); (100° at 4 mm.). V.D. 5.35 (obs.). S.G.  $d_4^{20}$  1.0204;  $d_4^{20}$  1.0123. Prepared by the action of sodium on a mixture of (a)-bromo-naphthalene and ethyl bromide (Fittig & Remsen, *Z.* [2] 5, 37; *A.* 155, 118). Colourless liquid. Partially decomposed on distillation. Br gives a tri-bromo-derivative [127°].—Picric acid compound: fine yellow needles [98°] (Carnelutti, *B.* 13, 1671; *G.* 10, 888).

(b) **Ethyl-naphthalene**  $C_{12}H_{12}$ . (251°). S.G. 1.0078. Colourless liquid. Solidifies at -19°. Prepared by the action of sodium on a mixture of (b)-bromo-naphthalene and ethyl bromide

(Brunel, *B.* 17, 1179). It is also formed (probably together with the (a)-ethyl-naphthalene) by the action of  $Al_2Cl_6$  on a mixture of naphthalene (100 pts.) and ethyl bromide or chloride (50 pts.) (Marchetti, *G.* 11, 265, 439). EtBr gives the best yield (Roux, *A. Ch.* [2] 12, 289).—Picric acid compound: [69°] (B.); [71°] (M.); yellow needles or long plates.

(a) **ETHYL-NAPHTHALENE SULPHONIC ACID**  $C_{12}H_{11}SO_3H$ . Forms an amorphous Ba salt and a crystalline copper salt  $CuA'$ , 2aq, m. sol. water.

(b) **Ethyl-naphthalene sulphonic acid**  $C_{12}H_{11}SO_3H$ . From (b)-ethyl-naphthalene and  $H_2SO_4$ . Forms a lead salt  $PbA'$ , crystallising in scales (Marchetti, *G.* 11, 439).

**ETHYL-NAPHTHOIC ACID**. *Amide*  $C_{10}H_7Et.CONH_2$ . [144]. [166°]. Formed by acting on (a)-ethyl naphthalene with chloro-formic amide in presence of  $Al_2Cl_6$  (Gattermann, *A.* 244, 57). Colourless needles (from alcohol). On hydrolysis (1.4) ethyl-naphthoic acid [132°] is obtained.

(b) **ETHYL-NAPHTHOL**  $C_{10}H_7Et.OH$ . [98°]. Obtained by fusing (b)-ethyl-naphthalene sulphonic acid with potash (Marchetti, *G.* 11, 442). Silvery leaflets, insol. cold water, v. sol. alcohol and ether.

**ETHYL-NAPHTHYL-AMINE** v. *NAPHTHYL-ETHYL-AMINE*.

**ETHYL-NAPHTHYLENE-DIAMINE** v. *NAPHTHYLENE-ETHYL-DIAMINE*.

**ETHYL NITRATE**  $C_2H_5NO_3$ . *Nitric ether*. Mol. w. 91. (86°) at 728 mm. S.G.  $d_4^{20}$  1.132;  $d_4^{20}$  1.112 (Kopp, *A.* 98, 367). H.F.p. 40.780 (Th.); 30700 (Berthelot). H.F.v. 38,750 (Th.). S.V. 91.1 (Ramsay). Formed by distilling alcohol with an equal weight of  $HNO_3$  (S.G. 1.4) containing 3 p.c. of urea; the distillation must be stopped when two-thirds of the liquid has distilled over, otherwise an explosive reaction will set in (Millon, *A. Ch.* [3] 8, 239; Carey Lea, *Am. S.* [2] 32, 178). It may also be obtained by dropping absolute alcohol (10 g.) from a very fine pipette into conc.  $HNO_3$  (20 g.) cooled with ice and salt (Persoz, *Rép. Chim. pure*, 5, 30). Alcoholic  $AgNO_3$  boiled with EtI or EtBr does not yield ethyl nitrate, but aldehyde and ethyl nitrate. The  $EtNO_3$  may be supposed to be reduced by the alcohol at the moment of formation thus:  $EtNO_3 + C_2H_5.OH = EtNO_2 + C_2H_5O + H_2O$  (Bertrand, *Bl.* [2] 53, 566).

*Preparation*.—A mixture of alcohol (300 g.), urea nitrate (100 g.), and  $HNO_3$  (400 g. of S.G. 1.4) is distilled to half its volume, after which a mixture of alcohol (3 pts.) and nitric acid (4 pts.) is run in slowly so as to keep the level of the liquid constant. The nitric acid used must have been previously heated to boiling with 1 p.c. of urea and afterwards cooled (Jossen, *A. Suppl.* 6, 220; Bertoni, *G.* 6, 406).

*Properties*.—Colourless oil with pleasant odour and sweet taste; miscible with alcohol and ether. It burns with a white flame.

*Reactions*.—1. Alcoholic  $NH_3$  at 100° gives ethylamine nitrate  $NEt_2.HNO_3$  (Juncadella, *C. R.* 48, 842). A mixture of nitric ether (1 vol.), alcohol (1 vol.), and conc.  $NH_3$  aq (1 vol.) at 100° forms mono-, di-, and tri-ethylamine (Lea).—2. *Ammonium sulphide* in alcoholic solution yields mercaptan (E. Kopp, *J. Ph.* [3] 11, 391).

8. Tin and HCl reduce it to hydroxylamine and di-ethyl-hydroxylamine (Lossen). — 4. When heated with ferrous acetate nitrogen is given off (Les).

**ETHYL NITRITE**  $C_2H_5NO$ , *i.s.* Et.O.NO. Nitrous ether. Mol. w. 75. (18°). S. 2. S.G.  $\frac{8}{9}$  919; 125-900 (Brown, Ph. 15,400). H.F.p. 30,610. H.F.v. 28,870. Produced by the action of nitric acid upon alcohol. The reaction is very violent, the alcohol being oxidised to aldehyde, &c., while the nitric acid is reduced to nitrous acid which etherifies the remaining alcohol (Kunkel, A.D. 1681; Dumas a. Boullay, A. Ch. [2] 37, 15). 'Sweet spirit of nitre' is obtained by distilling an excess of alcohol with  $HNO_3$ . Alcohol may be saved by adding copper, starch, or sugar to the mixture; or the ether may be obtained by passing nitrous fumes into alcohol (Liebig, A. 30, 142; E. Kopp, J. Ph. [3] 9, 320; Grant, Ph. 10, 244; Feldhaus, A. 126, 71).

**Preparation.**—34.5 g.  $NaNO_2$  dissolved in 120 c.c. of water are cooled below 0°; 13.5 c.c.  $H_2SO_4$  are added to 32 c.c. rectified spirit mixed with an equal volume of water, and the mixture diluted to 120 c.c. and cooled. The acid mixture is added gradually to the nitrite solution and the ether separated by a tap funnel, washed with water, and dried over ignited  $K_2CO_3$ . Glycerin (5 p.c.) added to the 2 p.c. alcoholic solution prevents its decomposition (Dunstan a. Dymond, Ph. 18, 861).

**Properties.**—Liquid, with characteristic odour; miscible with alcohol, al. sol. water. Decomposes when kept in a wet state, giving off NO. Saponified by solid KOH giving  $KNO_2$  and alcohol (Liebig a. Strecker, A. 77, 331). Reduced by  $H_2S$  or ammonium sulphide to alcohol and  $NH_3$ . Diazotises aromatic amido-compounds.

**ETHYL-NITRO. v. Nitro-ethyl.**

**ETHYL-NITROLIC ACID**  $C_2H_5N_2O_5$ , *i.e.*  $CH_3C(NO_2)_2NOH$  or  $CH_3CH(NO_2)_2NO$ . [82°].

**Formation.**—1. By the action of potassium nitrite and  $H_2SO_4$  on an alkaline solution of nitro-ethane (V. Meyer, B. 6, 1494; 7, 425; A. 180, 170).—2. From di-bromo-nitro-ethane and hydroxylamine in the cold.

**Preparation.**—From nitro-ethane (6 c.c.), ice, potash (15 c.c., containing 6.7 g. KOH), and  $NaNO_2$  (15 c.c. containing 8 g.). Dilute  $H_2SO_4$  is added, and the product extracted by ether (v. Meyer a. E. J. Constat, A. 214, 329).

**Properties.**—Light-yellow transparent trimetric prisms resembling  $KNO_3$ . Tastes sweet, and has an acid reaction. V. e. sol. warm, al. sol. cold, water. Dissolves in aqueous alkalis and in baryta, giving a deep red solution. An ethereal solution is not coloured by dry  $NH_3$ , until water is added. Lead acetate gives a brilliant orange pp.  $AgNO_3$  gives an egg-yellow pp.

**Reactions.**—1. When heated to 82° it melts, and is completely decomposed, thus:

The same decomposition occurs slowly in the cold, and quickly on boiling with an alkali.—

2. Sodium amalgam reduces it to acetic acid, nitrous acid, and  $NH_3$ . Tin and HCl act in the same way. In the case of sodium amalgam, ethyl-azauric acid is an intermediate product.—3. Conc. sulphuric acid splits it up into acetic acid and  $N_2O$ .

Isomeride of ethyl-nitrollic acid  $C_2H_5N_2O_5$ , [75°]. Formed by the action of sodium amalgam upon nitro-ethane (Kissel, B. [2] 40, 72; J. R. 15, 91). Prisms or needles (from chloroform). Acid in reaction, and forms salts with alkalis, but their solutions are not red.

**ETHYL-NITRO-PHENYL. v. Nitro-phenyl-ethyl.**

**DI-ETHYL-NITROSAMINE v. Di-ethyl-amine.**

**DI-ETHYL-ISO-NITROSO-AMYL-AMINE**  $NEt_2(C_4H_9NOH)$ . [72°]. Large flat crystals obtained by acting on Guthrie's amylene nitrite with diethylamine (Wallach, A. 241, 304).

**ETHYL n-OCTYL OXIDE**  $Et.O.C_8H_{17}$ , (189-2°). S.G.  $\frac{8}{9}$  8008. S.V. 244-9. C.E. (0°-10°) 00101 (Dobriner, A. 243, 6). (188°). S.G. 12 805 (Möslinger, A. 185, 57).

**ETHYL-OXALIC ACID v. Oxalic acid.**

Di-ethyl-oxalic acid v. Oxy-hexoic acid.

**ETHYL-OXALYL-ANTHRANILIC ACID v. Carboxy-phenyl-oxamic acid.**

**ETHYL-OXAMIC ACID**  $C_2H_5NO$ , *i.e.*  $NHET.CO.CO_2H$ . [120°]. Formed by heating the acid oxalate of ethylamine (Wurtz, A. Ch. [3] 30, 443). Its ether is obtained by treating oxalic ether with ethylamine, and may be saponified by boiling water or by milk of lime (Wallach a. West, B. 8, 760; A. 184, 58; cf. Heintz, A. 127, 43). Six-sided tables, v. sol. water, alcohol, and ether. May be extracted from its aqueous solution by ether. Sublimes in woolly needles. Cold conc. KOH aq decomposes it, giving off ethylamine. Boiling  $NH_3$  aq does not act on it.— $CaA_2$  2aq: prisms.— $CaA_2$  4aq (Duvillier a. Buisine, A. Ch. [5] 23, 349). S. 3-17 at 17-5°.— $BaA_2$  aq.

**Ethyl ether EtA'. Ethyl-oxamethane.** (245°). Formed as above. Liquid, miscible with water, alcohol, and ether. Saponified by hot water.  $NH_3$  converts it into ethyl-oxamide  $NHET.CO.CO.NH_2$ .  $PCl_5$  gives crystalline  $CO_2Et.CCl_2.NHET$  [above 50°], which is slowly decomposed at 100°, giving off  $EtCl$  and  $CO_2$ .

**Di-ethyl-oxamic acid**  $NEt_2.CO.CO_2H$ . [101°]. Prepared by saponification of the ether (Wallach, B. 14, 743; A. 214, 270). Large monoclinic prisms. V. sol. water and alcohol. Split up by heat into  $CO_2$  and di-ethyl-fofamide.  $PCl_5$  forms  $NEt_2.CO.COCl$ .— $CaA_2$  2aq: v. e. sol. water and boiling alcohol.

**Ethyl ether EtA'. (252°).** Formed by treating oxalic ether with diethylamine (Hofmann, Pr. 11, 66; B. 3, 779; Heintz, A. 127, 52).

**Nitrile**  $NEt_2.CO.ON$ . (220°). From unsymmetrical di-ethyl-oxamide,  $NEt.CO.CONH_2$ , and  $P_2O_5$  (Wallach, A. 214, 264). Liquid. Sl. sol. water. Volatile with steam. Lighter than water. Gives with  $PCl_5$  a little chloro-oxal-ethylene.

**ETHYL-OXAMIDE**  $C_2H_5N_2O_3$ , *i.e.*

$NH_2.CO.CO.NHET$ . [203°]. From ethyloxamic ether and  $NH_3$ , or from oxamic ether and ethylamine (Wallach, A. 184, 65). Flexible needles; may be sublimed. V. sol. hot water.

**n-Di-ethyl-oxamide**  $CONH_2.CONEt_2$ . [127°]. (267° cor.). From diethyl-oxamic ether and cold aqueous  $NH_3$  (Wallach, A. 214, 260). Long prisms; sublimes at 100°. Sol. hot water and

alcohol. Converted by  $\text{PCl}_5$  into chloro-oxal-ethylene  $\text{C}_2\text{H}_2\text{Cl}_2\text{N}_2$ . (Yield, bad.)

**Di-ethyl-oxamide**  $\text{CO}(\text{NHET})_2\text{CO.NHET}$ . [175°] (Wallach, A. 214, 268); [179°] (Schiff, B. 17, 1034). S.G.  $\pm 1.189$  (Schröder, B. 12, 1611). From oxalic ether and aqueous ethylamine (Wurtz, A. Ch. [3] 80, 490). Needles. More soluble in water and alcohol than oxamide. May be sublimed in crystals. Potash converts it into ethylamine and oxalic acid.

**Triethyl-oxamide**  $\text{NHET.CO.CO.NET}_3$ . (253°). Obtained from strong aqueous ethylamine solution and diethyl-oxamic ether  $\text{NET}_2\text{CO.COEt}$ . Liquid; miscible with water; decomposed by  $\text{PCl}_5$  (Wallach, A. 214, 267).

**ETHYL-OXANTHRANOL** v. **OXANTHRANOL**.

**DI-ETHYL-OXETHYL-AMINE** v. **OXY-TRI-**

**ETHYL-AMINE**.

**DI-ETHYL OXIDE** v. **ETHER**.

**Ethyl peroxide**  $(\text{C}_2\text{H}_5)_2\text{O}_2$  (?). Obtained by passing a slow current of dry ozonised oxygen over dry ether (Berthelot, C. R. 92, 895; A. Ch. [5] 27, 229). Syrupy liquid; does not solidify at  $-40^\circ$ . Explodes when distilled. Decomposed by water into alcohol and  $\text{H}_2\text{O}_2$ .

**ETHYL-OXINDOLE** v. **OXINDOLE**.

**ETHYL-OXY** v. *Ethyl derivatives of Oxy-*.

**DI-ETHYL-OXYALLYL-AMINE**

$\text{NET}_2\text{C}_2\text{H}_4\text{OH}$ . (c.  $160^\circ$ ). The most volatile of the bases obtained by the action of epichlorhydrin on di-ethyl-amine (Reboul, C. R. 97, 1188, 1556). Thick liquid with powerful odour resembling that of diethylamine. V. sol. water.  $\text{HCl}$  followed by  $\text{PtCl}_4$  gives  $[\text{NET}_2\text{C}_2\text{H}_4\text{Cl}(\text{OH})]_2\text{H}_2\text{PtCl}_4$  crystallising in garnet-red prisms; the corresponding base  $\text{NET}_2\text{C}_2\text{H}_4\text{Cl}(\text{OH})$  is the first product of the action of  $\text{NET}_3\text{H}$  on epichlorhydrin.

**ETHYL-OXY-PROPYL-AMINE**

$(\text{C}_2\text{H}_5\text{OH})(\text{C}_2\text{H}_5)\text{NH}$ . (c.  $160^\circ$ ). Formed by heating ethyl-allyl-amine with  $\text{H}_2\text{SO}_4$  and pouring the product into water.— $\text{B}^+\text{H}_2\text{Cl}_2\text{PtCl}_4$  2aq; v. sol. water (Liebermann, B. 16, 531).

**Oxy-propyl-di-ethyl-amine**  $\text{C}_2\text{H}_5\text{ON}$  i.e.  $\text{CH}_3(\text{OH}).\text{CH}_2.\text{CH}_2.\text{N}(\text{C}_2\text{H}_5)_2$ . *Trimethylene-di-ethylamine*. (190°). S.G.  $\frac{4}{5} = 9199$ . Colourless liquid. Miscible with water. Formed by heating trimethylene-chlorhydrin with di-ethyl-amine. The platino-chloride forms very soluble orange-red prisms; the aurochloride forms thick plates; the picrate long soluble needles (Berend, B. 17, 512).

**Di-ethyl-oxypropyl-amine**  $\text{C}_2\text{H}_5\text{NO}$ . (159°). *Di-ethyl-propyl-alkine*. Prepared by the action of diethylamine on propylene-chlorhydrin. ( $\text{B}^+\text{HCl}$ ),  $\text{PtCl}_4$ . V. sol. water (Ladenburg, B. 14, 2407).

**Di-ethyl-di-oxypropyl-amine**  $\text{C}_2\text{H}_5\text{NO}_2$  i.e.  $\text{NET}_2\text{CH}_2.\text{CH}(\text{OH}).\text{CH}_2\text{OH}$ . *Di-ethyl-propyl-glycolline*. (234°). Colourless oil. Soluble in water, alcohol, and ether. Formed by heating di-ethyl-amine with glycerine-chlorhydrin.— $\text{B}^+\text{H}_2\text{Cl}_2\text{PtCl}_4$ : reddish-yellow tables (Roth, B. 16, 1151).

**Benzoyl derivative**

$\text{NET}_2\text{CH}_2.\text{CH}(\text{OH}).\text{CH}(\text{OBz})$ . Thick liquid. Its picrate  $\text{C}_2\text{H}_5\text{NO}_2\text{C}_6\text{H}_4(\text{OH})(\text{NO}_2)_2$  crystallises in yellow plates; v. sl. sol. water.

**ETHYL-OXYPROPYL-ANILINE**

$\text{C}_2\text{H}_5.\text{N}(\text{C}_2\text{H}_5)(\text{C}_2\text{H}_4\text{OH})$ . *Ethyl-phenyl-propyl-alkine*. (262°). Colourless liquid. Insoluble in water. Very weak base. Formed by heating

ethyl-aniline with propylene-chlorhydrin (Lœun, B. 17, 678).

**DI-ETHYL-OXY-PROPYLENE-DIAMINE**

$\text{CH}_2(\text{OH}).\text{CH}(\text{NHET}).\text{CH}_2(\text{NHET})$ . (c.  $185^\circ$ ). From epichlorhydrin and ethylamine (Reboul, C. R. 97, 1488). Syrup, miscible with water.

**Tetra-ethyl-oxy-propylene-di-amine**

$\text{N}_2\text{HET}_2\text{C}_2\text{H}_4\text{OH}$  i.e.

$\text{CH}_2(\text{OH}).\text{CH}(\text{NET}_2).\text{CH}_2.\text{NET}_2$ .

According to Behrend (B. 17, 511) this base, obtained from diethylamine and the dichloride of allyl alcohol, is a liquid which cannot be distilled, but which forms an aurochloride  $\text{B}^+(\text{HAuCl}_4)_2$  that crystallises in plates, sl. sol. water, and also a *benzoyl derivative*  $\text{CH}_2(\text{OBz}).\text{CH}(\text{NET}_2).\text{CH}_2.\text{NET}_2$ , of which the platino-chloride  $\text{B}^+\text{H}_2\text{PtCl}_4$  forms orange-red needles.

**Tetra-ethyl-oxy-propylene-diamine**

$(\text{C}_2\text{H}_5\text{OH})(\text{C}_2\text{H}_5)_2\text{N}_2$  i.e.

$\text{CH}_2(\text{NET}_2).\text{CH}(\text{OH}).\text{CH}_2(\text{NET}_2)$ . *Tetra-ethyl-allyl-*

*alkine*. (235°). S.G.  $\frac{4}{5} = 9002$ . Colourless liquid, lighter than, and slightly soluble in, water. Formed by heating s-dichlorhydrin with diethylamine, or by mixing epichlorhydrin with diethylamine. The platino-chloride  $\text{B}^+\text{H}_2\text{PtCl}_4$  forms long thick soluble prisms; the aurochloride forms fine needles (Berend, B. 17, 510; Reboul, C. R. 97, 1488).

*Benzoyl derivative*  $\text{CH}(\text{OBz})(\text{CH}_2\text{NET}_2)_2$ . Gives an orange platino-chloride  $\text{B}^+\text{H}_2\text{PtCl}_4$ .

**ETHYL OXYSULPHIDE** v. **ETHYL SULPH-**

**OXIDE**.

**o-ETHYL-PHENOL**  $4:1[\text{C}_2\text{H}_5\text{Et}(\text{OH})]$ . *Phlorol*. Mol. w. 122. (211°) (O.); (220°) (C).

**Formation**.—1. From o-amido-phenyl-ethane by the diazo-reaction (Suida a. Plohn, *Sitz. W.* [2] 81, 245; *M.* 1, 175). When the amido-phenyl-ethane used is obtained by reducing the crude product of the nitration of ethyl-benzene the o-ethyl-phenol constitutes three-fourths of the resulting product.—2. By distilling barium phlorate with lime; phenol being also formed (V. Oliveri, G. 13, 263).—3. By fusing ethyl-benzene ( $\beta$ )-sulphonic acid with potash.—4. From its methyl ether.—5. By distilling gum ammoniac (1 pt.) with zinc-dust (10 pts.) (Ciamician, B. 12, 1658).

**Properties**.—Colourless liquid smelling like phenol. Liquid at  $-18^\circ$ . Sl. sol. water, v. sol. alcohol and ether. Gives a greenish colouration with ferric salts. Dissolves in alkalis. Yields salicylic acid and a small quantity of m-oxy-benzoic acid when fused with potash. Reacts with conc.  $\text{HNO}_3$  with explosive violence.

**Salt**.— $\text{Ba}(\text{O.C}_2\text{H}_5\text{Et})_2$  2aq; leaflets, decomposing at  $100^\circ$ .

**Methyl ether**  $\text{C}_2\text{H}_5\text{Et.OMe}$ . (185°) (O.); (191°) (S. a. P.). Heavy oil of pleasant ethereal odour. Not attacked by chromic acid mixture or by  $\text{KMnO}_4$ .

(a) **Ethyl-phenol**  $\text{C}_2\text{H}_5\text{Et}(\text{OH})$ . [47°]. (215°). Formed by fusing ethyl-benzene ( $\alpha$ )-sulphonic acid with potash (Beilstein a. Kuhlberg, A. 166, 211; Fittig a. Kiehoff, A. 156, 251). Needles. Sl. sol. water, v. e. sol. alcohol and ether. Its aqueous solution is coloured greenish-blue by  $\text{FeCl}_3$ . When heated with  $\text{P}_2\text{O}_5$  it gives phenyl phosphate and ethylene (Chrustershoff, B. 7, 1165). Conc.  $\text{HNO}_3$  gives  $\text{CO}_2$  and oxalic acid.

**Ethyl-phenol**  $\text{C}_2\text{H}_5\text{Et.OH}$ . (204°-215°) (E.). S.G.  $\frac{4}{5} = 1.049$  (A.). Prepared by heating a mix-

ture of phenol and ethyl alcohol with zinc-chloride (Auer, B. 17, 669). A mixture of ethyl-phenols is formed by this process (Errera, G. 14, 484). Its aqueous solution is coloured greenish by ferric chloride.

*Ethyl ether*  $C_2H_5Et(OEt)$ . (200°) (E). Oxidised by  $KMnO_4$  to *p*-oxy-benzoic ether.

*Acetyl derivative*  $C_2H_5Et(OAc)$ . (c. 225°). Di-ethyl-phenol  $C_2H_5Et(OH)$  [1:3:4?]. (225°).

From *m*-di-ethyl-benzene. Gives a bluish-violet colour with  $FeCl_3$ .

*Reference*.—DI-BROMO-ETHYL-PHENOL.

**ETHYL-PHENOL CARBOXYLIC ACID** v. OXY-ETHYL-BENZOIC ACID.

**ETHYL-PHENOL-PHTHALEIN**  $C_{21}H_{18}O_4$ . Formed by heating ethyl-phenol with phthalic anhydride and  $ZnCl_2$  (Auer, B. 17, 671). Grey crystalline powder (containing aq.). V. sol. alcohol and ether, insol. water. Dissolves in alkalis forming a violet solution.

**o-ETHYL-PHENOL SULPHONIC ACID**  $C_2H_5Et(OH)SO_3H$ . From *o*-ethyl-phenol and conc.  $H_2SO_4$  (Suida a. Plohn, *Sitz. W.* [2] 81, 245; *M.* 1, 179). Very deliquescent minute needles.— $BaA'$ , caq.; pearly plates. Its solution gives a white pp. with lead salts and a dirty-green pp. with copper salts.

(a)-Ethyl-phenol sulphonic acid  $C_2H_5Et(OH)SO_3H$ . From (a)-ethyl-phenol and conc.  $H_2SO_4$  (Fittig a. Kiesoff, A. 156, 254).— $BaA'$ , prisms. S. 4' at 17° (Baumann, *H.* 4, 813).— $BaC_2H_3O_4$ ; insol. water.

**ETHYL-DIPHENYL**  $C_6H_5.C_2H_5(C_6H_5)$ . [1:3]. (284°). S.G. 2 1.043. Formed by treating melted diphenyl and  $AlCl_3$  with  $C_2H_5Cl$ ,  $C_2H_5Br$ , or with  $C_2H_5I$ . The  $C_2H_5Br$  gives the best yield (Adam, A. Ch. [6] 15, 251; *Bl.* [2] 47, 689). Colourless, mobile liquid. Oxidised with chromic acid it gives  $C_6H_5.C_2H_5.CO_2H$  [1:3] [161°]. Traces of  $C_6H_5.C_2H_5.CO_2H$  can be obtained as an intermediate product. Bromine at 180° easily produces a dibromide  $C_6H_4Br_2$  [103°]. Insol. alcohol and ether.

Di-ethyl-diphenyl  $C_6H_5.C_2H_5(C_6H_5)_2$ . S.G. 2 .999. (c. 307°). Formed by treating melted diphenyl and  $AlCl_3$  with  $C_2H_5I$ ,  $C_2H_5Cl$ , or  $C_2H_5Br$ , the latter giving the best yield (Adam). A colourless liquid. When oxidised with chromic acid (1,3,5) diphenyl-di-carboxylic acid is obtained.

*Reference*.—DI-AMIDO-DI-ETHYL-DIPHENYL.

**ETHYL-PHENYL** v. PHENYL-ETHYL.

**ETHYL-PHENYL-ACETIC ALDEHYDE**  $C_2H_5Et.CH_2CHO$ . From di-ethyl-benzene by successive treatment with  $CrO_2Cl_2$  and water (Etard, A. Ch. [5] 22, 255). Liquid. Volatile with steam. Decomposed by heating to 220°. Combines with  $NaHSO_4$ .

**ETHYL-PHENYL-AMIDO-NAPHTHOQUINONE** v. NAPHTHOQUINONE-ETHYL-ANILIDE.

**ETHYL-PHENYL-AMINE** v. AMIDO-PHENYL-ETHANE.

**TRI-ETHYL-PHENYL-AMMONIUM HYDROXIDE** v. *Ethylhydroxide* of DI-ETHYL-AMIDES.

**TRI-ETHYL-PHENYL-ARSONIUM** compounds v. ARSENIC, *Organic compounds of*.

**ETHYL-PHENYL BENZYL KETONE** v. BENZYL ETHYL-PHENYL KETONE.

**p-ETHYL-PHENYL-p-ISOBUTYL-PHENYL-THIO-UREA**  $C_6H_5.C_2H_5.NH.SONH.C_4H_9(C_6H_5)$ . *Phenethyl-phenisobutyl-thiourea*. [140°]. Formed

from *p*-ethyl-phenyl thiocarbimide and *p*-butyl-phenyl-amine (Mainzer, B. 16, 2025). Small white prisms. Sol. hot alcohol. By phosphoric acid it is split up into *p*-isobutyl-phenyl thiocarbimide *p*-ethyl-phenyl thiocarbimide, *p*-isobutyl-phenyl-amine, and *p*-ethyl-phenyl-amine.

**ETHYL-PHENYLENE-DIAMINE** v. PHENYL-ETHYL-DIAMINE.

**ETHYL-DI-PHENYL-ETHANE** v. PHENYL-ETHYLPHENYL-ETHANE.

**ETHYL-DI-PHENYL-ETHYLENE**

$C_6H_5.CH:CH.C_6H_5Et$ . [90°]. Formed from  $Ph.CH_2.CH(OH).C_2H_5Et$  and boiling dilute  $H_2SO_4$  (Söller, B. 15, 1681). Plates, v. e. sol. ether.

Di-ethyl-di-phenyl-ethylene

$C_6H_5Et.CH:CH.C_6H_5Et$ . *Di-ethyl-stilbene*. [135°]. Obtained by distilling the product of the action of  $H_2SO_4$  on a mixture of ethyl-benzene and  $Et.O.CHCl.CHCl$  (Hepp, B. 7, 1414). Pearly plates (from alcohol); sl. sol. cold alcohol, v. sol. ether. Boiling dilute  $HNO_3$  oxidises it to terephthalic acid. It combines with Br.

**DI-p-ETHYL-PHENYL-GUANIDINE**

$HN:C(NH.C_2H_5)_2$ . *Di-p-phenethyl-guanidine*. [188°]. Formed by the action of alcoholic  $NH_3$  and lead oxide upon di-*p*-ethyl-phenyl-thio-urea (Paucksch, B. 17, 2804). Large transparent tables. V. sol. alcohol, ether, and  $CS_2$ .— $B'H.Cl.PtCl_4$ ; glistening plates.

**ETHYL-DI-PHENYL-KETONE** v. PHENYL-ETHYL-PHENYL-KETONE.

**DI-ETHYL-PHENYL-METHANE** v. AMYL-BENZENE.

**p-ETHYL-PHENYL-(a)-NAPHTHYL-THIO-UREA**  $C_{12}H_9NH.CS.NH.C_2H_5Et$ . *Phenethyl-(a)-naphthyl-thiourea*. [148°]. Prepared by mixing (a)-naphthyl thiocarbimide and ethyl-phenyl-amine in alcoholic solution (Mainzer, B. 16, 2022). Small white needles. Sol. hot alcohol and ether. By phosphoric acid it is split up into *p*-ethyl-phenyl-thiocarbimide, (a)-naphthyl-thiocarbimide, *p*-ethyl-phenyl-amine, and (a)-naphthylamine.

**p-Ethyl-phenyl-(β)-naphthyl-thio-urea**

$C_{12}H_9NH.CS.NH.C_2H_5Et$ . [159°]. Prepared as above, using (β)-naphthyl-thiocarbimide ((β)-naphthyl mustard-oil) (M.). Small plates (from alcohol). M. sol. hot alcohol and ether. Split up like the (a)-isomeride by phosphoric acid.

**DI-α-ETHYL-DI-PHENYL-PROPIONIC ACID**

$C_{12}H_{15}O_4$ , i.e.  $(C_6H_5.C_2H_5)_2:C(CH_3).CO_2H$ . [116°]. Prepared by dissolving ethyl-benzene and pyruvic acid in  $H_2SO_4$  (Böttiger, B. 14, 1597). Transparent tables. Sol. ether, chloroform, and ligroin.

**ETHYL-PHENYL-PROPYL-ALKINE** v.

ETHYL-OXYPROPYL-ANILINE.

**ETHYL PHENYL SULPHONE** v. PHENYL-ETHYL SULPHONE.

**ETHYL-PHENYL DI-SULFOXIDE** v. BENZENE THIOSULPHONIC ACID.

**ETHYL-PHENYL-THIOBIURET** v. *Ethyl-derivative of* PHENYL-THIOBIURET.

**o-ETHYL-PHENYL THIOCARBIMIDE**

$C_6H_5(C_2H_5).NCS$ . (240°-245°). *o-Phenethyl-mustard oil*. Colourless mobile liquid. Formed by heating the thio-urea with phosphoric acid (Paucksch, B. 17, 2802).

**p-Ethyl-phenyl thiocarbimide**

$SCN.C_6H_5(C_2H_5)$ . *Phenethyl mustard oil*. (356°).

**Liquid.** Formed by distilling di-*p*-ethyl-phenyl-thio-urea with phosphoric acid (Mainzer, *B.* 16, 2020).

**Di-*o*-ETHYLPHENYL-THIO-UREA**

$C_{11}H_{13}N_2S$  i.e.  $SC(NH.C_6H_4Et)_2$ . [142°]. White needles. Obtained by heating *o*-amido-ethyl-benzene with  $CS_2$  and a little NaOH (Paucksch, *B.* 17, 767).

**Di-*p*-ethylphenyl-thio-urea**

$C_{11}H_{13}N_2S$  i.e.  $SC(NH.C_6H_4Et)_2$ . [145°]. Obtained by heating *p*-amido-ethyl-benzene with  $CS_2$  and a little NaOH (Paucksch, *B.* 17, 768; cf. Mainzer, *B.* 16, 2019). Pearly plates. Soluble in hot, sparingly in cold, alcohol.

**ETHYL-PHENYL-TOLUENE** v. BENZYL-ETHYL-BENZENE.

**Di-*p*-ETHYL-PHENYL-UREA**

$OC(NH.C_6H_4Et)_2$ . *Di-p*-phen-ethyl-urea. [217°]. Long transparent needles. Formed by the action of carbonyl chloride ( $COCl_2$ ) upon *p*-ethyl-phenylamine (Paucksch, *B.* 17, 2804).

**PENTA-ETHYL-PHILOROLUCIN**

$C_5Et_5O.H$  i.e.  $C_5Et_5O.(Et)_3(OH)$ . [92°]?

**Preparation.**—Philoroglucin (1 mol.) is warmed with KHO (3 mols.) and EtI (3 mols.) in alcoholic solution. The alcohol is finally distilled off and the residue dissolved with water and extracted with ether.

**Properties.**—Yellow indifferent body; when repeatedly crystallised from weak alcohol, it forms white plates. It is not acted on by boiling  $H_2Aq$ . It reacts with more EtI and KHO, showing that it still contains a HO group, forming an oil  $C_{15}H_{33}O_3$  or hexa-ethyl-philoroglucin  $C_5O_3Et_6$  (Herzig & Zeisel, *M.* 9, 217).

**ETHYL PHOSPHATES**

**Mono-ethylortho-phosphate**  $C_2H_5O.PO(OH)_2$ .

**Ethyl-phosphoric acid.** Formed by the action of phosphoric acid on alcohol or ether (Lassaigne, *A. Ch.* [2] 13, 294; Pelouze, *A. Ch.* [2] 52, 37; Liebig, *A. G.* 149; 13, 32; Church, *Fr.* 13, 520; Vogeli, *P.* 74, 282). A mixture of alcohol (1 pt. of 95 p.c.) with syrupy ortho- or pyro-phosphoric acid (1 pt.) is heated for some minutes to 70°, left to stand for 24 hours, and then diluted with water and neutralised with  $BaCO_3$ . The Ba salt is crystallised and decomposed by  $H_2SO_4$ .

**Properties.**—Colourless viscid liquid miscible with water, alcohol, and ether. It reddens litmus and tastes sour. It gives off ether, alcohol, and ethylene when heated. Distilled with KOAc it yields acetic ether.

**Salts.**—Soluble in water and crystalline. Most of them have a maximum degree of solubility at 40° to 60°. The lead salt is the least soluble:  $A_2A'$ ; feathery crystals (Church).— $BaA'$  6aq: prisms or tables.  $S.$  3.4 at 0°; 6.72 at 20°; 9.36 at 40°; 2.80 at 100°.— $BaA'$  aq (C).— $BaA'$  7aq (C).— $CaA'$  2aq: micaceous scales.— $FeA'$  8aq: straw-yellow films (C).— $Fe_2AlA'$  6aq (Church).— $FeAlA'$  8aq (C).— $FeAlA'$  6aq (Church).— $Fe_2A'$  6aq (Church).— $PbA'$  aq.— $HgA'$  2aq (?) (Church).— $UO_2A'$ : lemon-yellow mass.— $AgA'$  aq: crystalline.—Tetra-ethyl-ammonium salt  $(NEt_4)A'$ : deliquescent mass of crystals; split up by heat into triethylamine and tri-ethyl phosphate.

**Chloride**  $EtO.OPCl_2$ . (187°). Formed by the action of alcohol (1 mol.) on  $POCl_3$  (1 mol.) or by passing chlorine into a mixture of alcohol

(2 mols.) and  $PCl_3$  (1 mol.) (Wichelhaus, *A. Suppl.* 6, 265). Formed also by heating  $Et_2PO_3$  with  $POCl_3$  at 110° (Chambon, *J.* 1876, 305). Oil; split up at 160° into  $EtCl$ ,  $POCl_3$ , and  $P_2O_5$ , but may be distilled in a current of hydrogen. Decomposed by water into  $HCl$  and  $EtO.OP(OH)_2$ . PBr gives  $EtBr$ ,  $POBr_3$ , and  $POBrCl_2$ .

**Di-ethyl phosphate**  $(EtO)_2PO.OH$ . *Di-ethyl-phosphoric acid.* Prepared by placing  $P_2O_5$  in a dish over dry ether, or, better, alcohol under a bell-jar. In a fortnight the acid will have deliquesced, and the syrup may then be treated with  $PbCO_3$ . The resulting lead salt is decomposed by  $H_2S$  (Vogeli, *A.* 69, 180). Syrup; decomposed by heat.— $CaA'_2$ : silky groups of crystals (from water); v. sol. water, sl. sol. alcohol; gives off  $Et_2PO_3$  when heated.— $PbA'_2$ : [180°]; groups of crystals resembling caffeine (from water); v. sol. cold water and hot alcohol. At 190° it gives off  $Et_2PO_3$ , leaving  $PbEt_2PO_3$ .—The barium salt forms needles or laminae, v. sol. water.

**Chloride**  $(EtO)_2OPCl$ . From  $POCl_3$  (1 mol.) and alcohol (2 mols.) also from  $Et_2PO_3$  and  $Cl$  (W.).

**Bromide**  $(EtO)_2OPBr$ . From  $Et_2PO_3$  and  $Br$  (W.). Cannot be distilled.

**Tri-ethyl phosphate**  $Et_3PO$ , i.e.  $OP(OEt)_3$ . *Phosphoric ether.* (215°). *S.G.* 1.1072.

**Formation.**—1. By heating  $Pb(Et_2PO_3)_2$  to 190° (v. supra).—2. In small quantity in the preparation of di-ethyl phosphate (V.).—3. By heating  $Ag_3PO_3$  with  $AgI$  at 100°, exhausting the mass with ether, and distilling *in vacuo* (De Clermont, *A.* 91, 876).—4. From  $POCl_3$  and  $NaOEt$  (Limpriecht, *A.* 134, 347).—5. By treating dry alcohol with  $POCl_3$  or  $P_2O_5$  (Schiff; Carius, *A.* 137, 121).

**Properties.**—Limpid liquid with peculiar odour. In a current of hydrogen it boils at 203°. Sol. water, alcohol and ether. Slowly decomposed by contact with water forming  $HEt_2PO_3$ .  $POCl_3$  at 110° forms  $EtO.POCl_2$ . When  $PCl_3$  (1 pt.) mixed with pure ether is dropped upon dry  $NaOEt$  (6 pts.) suspended in ether and the product distilled in a current of hydrogen there is obtained a compound (158° cor.). *S.G.* 1.960 which may be  $C_4H_9P_2O_4$  or  $(Et_2PO_3)(Et_2PO_3)(EtOH)$ ; it is slowly split up by distillation into its components (Geuther, *A.* 224, 275).

**Ethyl metaphosphate**  $EtPO_3$ ? (below 100°). From lead metaphosphate and EtI (Carius, *J.* 1861, 586). Water converts it into  $EtH_2PO_3$ .

**Tetra-ethyl pyrophosphate**  $Et_4P_2O_7$ . *S.G.* 1.172. From silver pyrophosphate by heating at 100° with EtI (De Clermont, *A.* 91, 875). Viscid liquid with peculiar odour and burning taste. Decomposed by heat. Burns with whitish flame. Sol. water, alcohol, and ether. It turns acid when exposed to the air. Potash forms  $KEt_4P_2O_7$ .

**ETHYL-PHOSPHINE**  $C_2H_5.P$  i.e.  $PH_2Et$ . Mol. w. 62. (25°). When EtI and  $PH_3$  are heated together with ZnO at 150° there is formed  $PET_2H$  and  $PET_3H$ . On treating the product with water  $PET_2H$  is decomposed into HI and gaseous  $PET_3H$ , while  $PET_3H$  is not affected. If after expelling  $PET_3H$  aqueous NaOH be now added it will liberate  $PET_2H$  (Hofmann, *B.* 4, 432).  $PH_2Et$  is also formed when ethylene bromide,  $PH_3$ , and ZnO are heated together (Hofmann,

B. 6, 302). Very volatile liquid. It has no action on litmus. Has an overpowering odour; its vapour produces an intensely bitter taste in the throat. It bleaches cork. Takes fire with Cl, Br, or fuming  $\text{HNO}_3$ . Combines with S and  $\text{CS}_2$  forming liquid bodies.

**Salt.**— $\text{PEt}_2\text{HI}$ : four-sided tables, decomposed by water, partially decomposed by alcohol; insol. ether. It is ppd. in crystalline form by adding ether to its solution in conc.  $\text{HIAg}$ .

**Ethyl-di-chloro-phosphine  $\text{EtPCL}_2$ .** *Ethyl-phosphorous chloride.* (110°). Formed by heating  $\text{PCL}_3$  (4 pts.) with mercuric ethide  $\text{HgEt}_2$  (1 pt.) (Michaelis, B. 18, 2174). Liquid smelling like apples. Fumes in the air. Is readily decomposed by water. With Cl it gives  $\text{EtPCL}_3$ , a solid which decomposes at 100°–150° and is converted by water into  $\text{EtPOCl}_2$ , a liquid boiling about 175°, which is decomposed by further treatment with water.

**Di-ethyl-phosphine  $\text{Et}_2\text{PH}$ .** Mol. w. 90. (85°). Is prepared as above (Hofmann, B. 4, 433). Oil with powerful odour; lighter than water. Absorbs oxygen from the air, sometimes taking fire. Combines directly with sulphur and with  $\text{CS}_2$  forming liquid compounds. Its salts crystallise with difficulty.

**Tri-ethyl-phosphine  $\text{PEt}_3$ .** Mol. w. 118. (128°). S.G. 1.812.

**Formation.**—1. By the action of  $\text{PCL}_3$  on  $\text{ZnEt}_2$  (Hofmann a. Cahours, C. J. 11, 56; A. 104, 1; Suppl. 1, 2). The tri-ethyl-phosphine remains combined with  $\text{ZnCl}_2$  but may be liberated by distillation with aqueous potash.—2. By the action of phosphide of sodium on  $\text{EtI}$  (Berlé, J. pr. 66, 78).—3. When a mixture of zinc phosphorus, and dry  $\text{EtI}$  is heated at 155° there is produced, together with  $\text{ZnEt}_2$ , a mixture of  $(\text{PEt}_2\text{HI})_2\text{ZnI}_2$  with  $(\text{PEt}_2)_3\text{ZnI}_2$  and  $(\text{PEt}_2\text{O})_2\text{ZnI}_2$ . These compounds may be separated by water, the first being the least and the second the most soluble. The first yields  $\text{PEt}_2$ , when treated with cold potash, the third yields it when heated with solid  $\text{KOH}$  (Hofmann, C. J. 13, 291).—4. When zinc phosphide obtained by passing dry  $\text{PH}_3$  into a well-cooled ethereal solution of  $\text{ZnEt}_2$ , is heated with (5 pts. of)  $\text{EtI}$  at 150° it forms  $(\text{Et}_2\text{PHI})_2\text{ZnI}_2$  (Drechsel a. Finkelstein, B. 4, 353).

**Preparation.**—1.  $\text{PCL}_3$  is allowed to drop slowly into an ethereal solution of  $\text{ZnEt}_2$ , placed in a retort filled with  $\text{CO}$ , connected with a tubulated receiver. The reaction is violent, and, to avoid loss, the other tubule of the receiver is connected with a V tube containing  $\text{PCL}_3$ , communicating with a vessel full of  $\text{CO}_2$ . The liquid separates into two layers, the lower being the zinc double salt of  $\text{PEt}_2$ ; this salt is distilled with aqueous  $\text{KOH}$  in a current of hydrogen. It is dried with solid  $\text{KOH}$  and rectified in hydrogen (Hofmann, C. J. 13, 290).—2.  $\text{PH}_3\text{I}$  (1 mol.) is heated with alcohol (8 mols.) for 8 hours at 180°. The product containing  $\text{PEt}_2\text{HI}$  and  $\text{PEt}_2\text{I}$  is distilled with potash (Hofmann, B. 4, 207).

**Properties.**—Colourless, mobile, liquid. Its odour is very penetrating but not disagreeable; when diluted it smells like hyacinths. When freshly prepared it has no action on litmus, but if exposed for a few seconds to the air it becomes acid. It is insol. water, miscible with alcohol

and ether. It unites with acids forming very deliquescent salts.

**Reactions.**—1. Rapidly absorbs oxygen from the air, becoming  $\text{PEt}_2\text{O}$ . It often takes fire in pure oxygen, forming  $\text{P}_2\text{O}_5$ . Its vapour mixed with oxygen explodes when heated.—2. *Sulphur* combines with it forming  $\text{PEt}_2\text{S}$ .—3. *Selenium* gives  $\text{PEt}_2\text{Se}$ .—4. *Sulphide of carbon* unites with it forming red monoclinic crystals of  $\text{PEt}_2\text{CS}_2$  (95°). Hence  $\text{CS}_2$  and  $\text{PEt}_2$  may be used to detect one another; thus, when the vapour of  $\text{CS}_2$  is poured over a watch glass in which there is a liquid containing free  $\text{PEt}_2$ , a beautiful net-work of the red crystals will appear. The crystals are insol. water, sl. sol. ether, m. sol. warm alcohol and  $\text{CS}_2$ . They dissolve in conc.  $\text{HClAg}$ , forming a colourless solution from which they are re-ppd. by  $\text{KOH}$  unaltered. Water at 100° gives  $\text{PEt}_2\text{S}$ ,  $\text{PEt}_2\text{O}$ , and  $\text{PMeEt}_2\text{OH}$ . Boiling with alcohol and  $\text{Ag}_2\text{O}$  forms  $\text{PEt}_2\text{S}$  and  $\text{CO}_2$ .  $\text{H}_2\text{S}$  also gives  $\text{PEt}_2\text{S}$  and yellow crystals of  $\text{C}_2\text{H}_5\text{PS}$ , which are converted by hot water into  $\text{CS}_2$  and  $\text{C}_2\text{H}_5\text{PSO}$ , whence  $\text{C}_2\text{H}_5\text{PSI}$  may be prepared. Platinum chloride forms the compound  $(\text{PEt}_2\text{CS}_2)_2\text{H}_2\text{PtCl}_4$  an amorphous light yellow salt.—5. When  $\text{PEt}_2$  is poured into a flask containing chlorine every drop takes fire,  $\text{PCL}_3$ ,  $\text{HCl}$ , and carbon being formed. If the reaction be moderated a crystalline compound  $\text{PEt}_2\text{Cl}_2$  is formed. This melts near 100°, but has a very high boiling-point. Bromine and iodine act in the same way.—6. *Ethylene bromide* forms  $\text{CH}_2\text{BrCH}_2\text{PEt}_2\text{Br}$  and  $\text{C}_2\text{H}_4(\text{PEt}_2)_2\text{Br}_2$ . *Ethylidene bromide*, ethylidene chloride, and  $\text{EtCl}$  act in like manner. *Ethylene iodide*, however, acts with explosive violence, forming  $\text{PEt}_2\text{I}_2$  and ethylene.—7. *Chloro-acetic ether* forms  $\text{PEt}_2\text{ClCH}_2\text{CO}_2\text{Et}$  (Hofmann, Pr. 11, 525).—8. *Allyl thiocarbimide* (oil of mustard) forms  $\text{C}_3\text{H}_7\text{NCSPEt}_2$ , possibly  $\text{C}_3\text{H}_7\text{NCS}_2\text{PEt}_2$ . It forms large crystals (from ether) (68°) and gives with  $\text{H}_2\text{PtCl}_4$  the salt  $\text{B}'\text{H}_2\text{PtCl}_4$  (Hofmann, Tr. 1860, 440).—9. *Phenyl-thio-carbimide* forms in like manner 'phenyl-tri-ethyl-phospho-thio-urea'  $\text{CS}(\text{NPhEt})(\text{PEt}_2)_3$  (58°) (Hofmann, Tr. 1860, 432). It forms monoclinic crystals (from ether), isomorphous with  $\text{CS}(\text{NC}_2\text{H}_5)_2(\text{PEt}_2)_3$  and with allyl thio-urea. It decomposes at 100°. It is insol. water, sol. alcohol and boiling ether. It is very soluble in dilute acids, forms easily crystallisable salts.  $\text{HNO}_3$  forms phenyl thiocarbimide and  $\text{PEt}_2\text{O}$ . Boiling aqueous  $\text{NH}_3$  forms phenyl-thio-urea and  $\text{PEt}_2$ .  $\text{KOH}$  gives  $\text{PEt}_2$ , di-phenyl-thio-urea,  $\text{K}_2\text{S}$  and  $\text{K}_2\text{CO}_3$ .  $\text{CS}_2$  forms the red  $\text{PEt}_2\text{CS}_2$ . Phenyl-tri-ethyl-phospho-thio-urea forms the following combinations:  $\text{B}'\text{HCl}$ , cadmium yellow crystals, decomposed by boiling water.— $\text{B}'\text{H}_2\text{PtCl}_4$ .— $\text{B}'\text{MeI}$ : golden needles (from boiling water).— $(\text{B}'\text{MeCl})_2\text{PtCl}_4$ .— $\text{B}'\text{MeOH}$ : decomposed on boiling into  $\text{PhNCS}$  and  $\text{PEt}_2\text{MeOH}$ .—10. *Ethyl sulphocyanide* forms  $\text{PEt}_2\text{S}$  and  $\text{PEt}_2\text{Cy}$ .—11. Tri-ethyl-phosphine merely polymerises cyanic acid and its ethers.—12. *Mercaptan* even at 100° has no action unless air be present.—13. *Iodoform* reacts with rise of temperature, producing  $\text{CH}(\text{PEt}_2)_3\text{I}$ , which crystallises from alcohol. It is v. sol. water, sl. sol. alcohol, insol. ether. Aqueous  $\text{ZnI}_2$  gives in its solution a pp. of  $\{\text{CH}(\text{PEt}_2)_3\}_2\cdot 3\text{ZnI}_2$ . Platinum chloride gives  $\{\text{CH}(\text{PEt}_2)_3\}_2\cdot \text{PtCl}_4$ , which crystallises from alcohol in rectangular laminæ.

Moist  $\text{Ag}_2\text{O}$  forms  $\text{PEt}_2\text{Me}(\text{OH})$  and  $\text{PEt}_2\text{O}$  (Hofmann, *Fr.* 10, 189; 11, 290).—14. *Chloroform* or  $\text{CCl}_4$  give  $\text{CH}(\text{PEt}_2)_2\text{Cl}$ .—15. By dropping  $\text{PEt}_2$  upon cooled *chloro-acetic acid* in a vessel full of hydrogen there is formed  $\text{Et}_2\text{P}(\text{CH}_2)_2\text{CO}_2\text{H}$  'the hydrochloride of phosphorus betaine' (Letts, *Tr. E.* 30, 285; *Pr. E.* 11, 40). This compound crystallises from ether in colourless needles, it has an acid reaction, and its platinochloride forms thick light orange needles. The compound  $\text{Et}_2\text{P}(\text{CH}_2)_2\text{CO}_2\text{H}$  splits up at  $145^\circ$  into  $\text{CO}_2$  and  $\text{PEt}_2\text{MeCl}$ . Solid  $\text{KOH}$  gives  $\text{PEt}_2\text{O}$  and potassium acetate. Moist  $\text{Ag}_2\text{O}$  forms  $\text{Et}_2\text{P}(\text{OH})(\text{CH}_2)_2\text{CO}_2\text{H}$  which, when dried over  $\text{P}_2\text{O}_5$  in *vacuo*, becomes  $\text{Et}_2\text{P}(\text{O})(\text{CH}_2)_2\text{CO}$ , a very deliquescent neutral substance.  $\text{HBr}$  converts it into  $\text{Et}_2\text{PBr}(\text{CH}_2)_2\text{CO}_2\text{H}$ , which forms dimetric plates (from alcohol and ether). It is split up by heat into  $\text{CO}_2$  and  $\text{PEt}_2\text{MeBr}$ .  $\text{HI}$  converts  $\text{Et}_2\text{P}(\text{OH})(\text{CH}_2)_2\text{CO}_2\text{H}$  into very deliquescent granular crystals of the acid  $\text{Et}_2\text{P}(\text{CH}_2)_2\text{CO}_2\text{H}$ .  $\text{PEt}_2\text{Cl}(\text{CH}_2)_2\text{CO}_2\text{H}$  is converted by  $\text{Ag}_2\text{SO}_4$  into a very deliquescent sulphate which is split up by heat into  $\text{CO}_2$  and  $(\text{PEt}_2\text{Me})_2\text{SO}_4$ .—16.  $\text{PEt}_2$ , mixed with an equimolecular quantity of cooled *chloro-acetic ether* forms very deliquescent  $\text{PEt}_2\text{Cl}(\text{CH}_2)_2\text{CO}_2\text{Et}$  which melts below  $100^\circ$ , and at a higher temperature is split up into  $\text{PEt}_2\text{MeCl}$ ,  $\text{CO}_2$ , and ethylene. It forms a crystalline platinochloride, and is converted by moist  $\text{Ag}_2\text{O}$  into  $\text{Et}_2\text{P}(\text{O})(\text{CH}_2)_2\text{O}$ , alcohol,  $\text{PEt}_2\text{O}$ , and acetic ether. Solid  $\text{KOH}$  forms  $\text{PEt}_2\text{O}$ , acetic ether, and  $\text{KCl}$  (Letts, *Tr. E.* 30, 285).—17. *Bromo-acetic ether* forms in like manner an extremely deliquescent compound which melts below  $100^\circ$ , and is split up by heat into  $\text{PEt}_2\text{MeBr}$ ,  $\text{CO}_2$ , and ethylene (Letts).—18. *Bromo-acetic acid* forms a colourless liquid which if heated to  $100^\circ$  and allowed to cool solidifies. The product consists of at least two substances: one of these substances,  $(\text{PEt}_2\text{Br}.\text{O}.\text{CO}.\text{CH}_3)_2$ , when treated with potash yields  $\text{PEt}_2\text{O}$  and  $\text{KOAc}$ ; the other, which is perhaps  $\text{PEt}_2\text{H}.\text{O}.\text{CO}.\text{CH}_2\text{Br}$ , yields  $\text{PEt}_2$  with  $\text{KOH}$ . The first compound is also formed when  $\text{PEt}_2\text{O}$  is treated with acetyl bromide (Letts, *Tr. E.* 30, 285).

**Salts.**—The hydrochloride, hydrobromide, hydroiodide, sulphate, and nitrate are crystalline but extremely deliquescent.— $(\text{PEt}_2\text{HI})_2\text{ZnI}_2$ : tablets.— $(\text{PEt}_2)_2\text{H}_2\text{PtCl}_6$ : crystalline, sl. sol. cold water, insol. alcohol and ether. By boiling  $\text{PEt}_2$  with aqueous platinic chloride there are formed two isomeric compounds of the formula  $(\text{PEt}_2)_2\text{PtCl}_4$ , a white substance insol. ether, and a yellow substance crystallising from ether in prisms [ $150^\circ$ ]. The yellow substance is insol. water, and is converted into its isomeride by heating with alcohol at  $100^\circ$ . When boiled with water and  $\text{PEt}_2$ , it forms  $(\text{PEt}_2)_2\text{PtCl}_2$  (Cahours a. Gal, *Z.* 1870, 350, 437).— $(\text{PEt}_2)_2\text{PdCl}_2$ .— $(\text{PEt}_2)_2\text{PtCl}_4$ .— $(\text{PEt}_2)_2\text{PtCl}_2\text{AuCl}_2$ .— $(\text{PEt}_2)_2\text{AuCl}_2$ .

**Tri-ethyl-phosphine oxide**  $\text{PEt}_2\text{O}$ . Mol. w. 134. [ $44^\circ$ ] (H.); [ $53^\circ$ ] (P.). ( $243^\circ$  uncor.). V.D. 4.60 (calc. 4.66).

**Formation.**—1. From  $\text{PEt}_2$  by atmospheric oxidation or by gently heating it with  $\text{HgO}$  or  $\text{Ag}_2\text{O}$  (Cahours a. Hofmann, *A.* 104, 18).—2. By distilling  $\text{PEt}_2\text{OH}$ , the other product being

ethane.—3. By decomposing  $(\text{PEt}_2\text{Cl})_2\text{ZnCl}_2$  with solid  $\text{KOH}$  and a little water (Pebal, *A.* 120, 194).—4. From  $\text{EtOPCl}_2$  and  $\text{ZnEt}_2$  (Wichelhaus, *B.* 1, 80).—5. By heating clear phosphorus (1 pt.) with  $\text{EtI}$  (13 pts.) for 24 hours at  $180^\circ$ , and boiling the product with alcohol. The residue is evaporated and distilled with  $\text{KOH}$  (4 pts.) (Crafts a. Silva, *Z.* 1871, 359; cf. Carius, *A.* 136, 187). When  $\text{PI}_3$  (1 mol.) is heated with  $\text{EtI}$  (8 mols.) iodine is given off, and a body is left which when treated with solid  $\text{KOH}$  yields  $\text{PEt}_2\text{O}$  on distillation (Emmertson, *Am.* 4, 9).

**Properties.**—Slender white deliquescent needles. Dissolves in all proportions in water and alcohol, less sol. ether. Very slightly volatile with steam. Separates as a liquid when solid  $\text{KOH}$  is added to its aqueous solution, or when ether is added to its alcoholic solution. Converted by  $\text{HBr}$  into  $\text{PEt}_2\text{Br}$ , and by  $\text{HI}$  into  $\text{PEt}_2\text{I}$ . It is not affected by  $\text{H}_2\text{S}$  or by halogens. It forms crystalline compounds with some metallic salts:  $(\text{PEt}_2\text{O})_2\text{CuSO}_4$ : deliquescent, four-sided, green prisms (Pebal).— $(\text{PEt}_2\text{O})_2\text{ZnI}_2$ : [ $99^\circ$ ]; crystalline pp. which, when crystallised from alcohol, forms monoclinic crystals;  $a:b:c = .905:1:331$ ;  $\beta = 83^\circ 13'$ .

**Tri-ethyl-phosphine oxy-chloride**  $(\text{PEt}_2)_2\text{OCl}_2$ . By passing dry  $\text{HCl}$  over fused  $\text{PEt}_2\text{O}$  shining crystals are formed, which are dissolved in  $\text{HClAq}$  and the solution is then evaporated (Hofmann). Very deliquescent crystalline mass, sol. water and alcohol, insol. ether. The solution treated with platinic chloride in saturated alcoholic solution yields  $(\text{PEt}_2\text{O})_2\text{PtCl}_4$ , which crystallises from alcohol in large orange monoclinic prisms;  $a:b:c = .631:1:1578$ ;  $\beta = 73^\circ 42'$  (Hofmann, *Tr.* 1860, 419).— $(\text{PEt}_2)_2\text{OCl}_2\text{ZnCl}_2$ : transparent octahedra, sol. water and alcohol. By the action of  $\text{HCl}$  on  $\text{PEt}_2\text{O}$  Crafts a. Silva obtained a compound  $\text{PEt}_2(\text{OH})\text{Cl}$  [ $128^\circ$ ].

**Tri-ethyl-phosphine sulphide**  $\text{PEt}_2\text{S}$ . [ $94^\circ$ ].

**Formation.**—1. By adding flowers of sulphur to an ethereal solution of  $\text{PEt}_2$ , after evaporating the ether the residue is heated with boiling water which dissolves  $\text{PEt}_2\text{S}$  only, depositing it in crystals on cooling.—2. By distilling  $\text{PEt}_2$  with cinnabar.—4. By decomposing  $\text{PEt}_2\text{CS}_2$  with water or  $\text{Ag}_2\text{O}$ .—5. By the action of mercaptan on  $\text{PEt}_2$  in presence of air.

**Properties.**—Long hexagonal needles (from water);  $a:c = 1:821$ . Sol. water, v. sol. alcohol and ether, v. e. sol.  $\text{CS}_2$ . Volatile with steam. Decomposed by sodium giving  $\text{Na}_2\text{S}$  and  $\text{PEt}_2$ . It may be separated from its aqueous solution by  $\text{KOH}$ . Its aqueous solution is neutral to litmus, but it dissolves more readily in  $\text{HClAq}$  than in water, and the solution gives an unstable yellow pp. with platinic chloride. The aqueous solution is not affected by boiling aqueous lead acetate or  $\text{AgNO}_3$ , or by  $\text{HgO}$ , but these substances become sulphides when added to its alcoholic solution.

**Tri-ethyl-phosphine selenide**  $\text{PEt}_2\text{Se}$ . [ $112^\circ$ ]. From  $\text{PEt}_2$  and selenium. Crystallises from water, but turns red if air.

**Tetra-ethyl-phosphonium compounds.**

$\text{PEt}_2(\text{OH})$ . When  $\text{PEt}_2\text{I}$  is digested with water and  $\text{Ag}_2\text{O}$  there is formed a strongly alkaline bitter solution, which dries up over  $\text{H}_2\text{SO}_4$  to an extremely deliquescent crystalline mass. This solid hydroxide absorbs  $\text{CO}_2$  with avidity. Its solution behaves like  $\text{KOH}$  towards solutions of me-

tallic salts; alumina and zinc hydrate, however, dissolve less readily in excess of  $\text{PEt}_2\text{OH}$  than in  $\text{KOH}$ .  $\text{PEt}_2\text{OH}$  is split up by heat into  $\text{PEt}_2\text{O}$  and ethane.— $(\text{PEt}_2)_2\text{SO}_4$ : split up by heat into  $\text{PEt}_2\text{S}$ ,  $\text{PEt}_2\text{O}$ , and charred products. Chlorine at  $180^\circ$  forms  $(\text{PEt}_2)_2\text{SO}_4\text{Cl}_2$ , a yellow body (Masson & Kirkland, *C. J.* 55, 133). Bromine vapour at  $110^\circ$  gives  $(\text{PEt}_2)_2\text{SO}_4\text{Br}_2$  and  $(\text{PEt}_2)_2\text{SO}_4\text{Br}$ .— $(\text{PEt}_2)_2\text{CO}_2$ : resolved by heat into  $\text{PEt}_2\text{O}$ ,  $\text{PEt}_2\text{O}$ , di-ethyl-ketone,  $\text{C}_2\text{H}_4$ , and  $\text{CO}_2$ .— $\text{PEt}_2\text{Cl}$ : deliquescent. Resolved by heat into  $\text{C}_2\text{H}_4$  and  $\text{PEt}_2\text{HCl}$  (Letts & Collie, *C. J.* Proc. 2, 164).— $\text{PEt}_2\text{Cl}_2$ : deliquescent; decomposed by water, forming  $\text{PEt}_2\text{Cl}$  (Masson & Kirkland, *C. J.* 55, 132).— $\text{PEt}_2\text{AuCl}_2$ : yellow needles (from water).— $(\text{PEt}_2)_2\text{Cl}_2$ : regular octahedra (from water); sl. sol. boiling water, insol. alcohol and ether.— $(\text{PEt}_2)_2\text{Cl}_2\cdot 2\text{BiCl}_3$ : six-sided tables (Jørgensen, *J. pr.* [2] 3, 345).— $(\text{PEt}_2)_2\text{Cl}_2\cdot \text{ZnCl}_2$ : from  $\text{ZnEt}_2$  by gradual addition of  $\text{POCl}_3$  followed by water (Pebal, *A.* 120, 198); colourless dimetric crystals, permanent in the air and v. sol. water.— $(\text{PEt}_2)_2\text{Br}_2\cdot 2\text{BiBr}_3$  (J.).— $\text{PEt}_2\text{Br}$ : formed by evaporating an alcoholic solution of the following salt. Red crystals.— $\text{PEt}_2\text{Br}$ : from  $\text{PEt}_2\text{Br}$  and bromine vapour at  $110^\circ$ . Violet crystals (M. & K.).— $\text{PEt}_2\text{ICl}_2$ .— $\text{PEt}_2\text{IBr}$ .— $\text{PEt}_2\text{I}$ .— $\text{PEt}_2\text{I}$ : formed with great violence when  $\text{PEt}_2$  and  $\text{EtI}$  are mixed. Rhombohedra, isomorphous with  $\text{AgI}$ . V. sol. water, m. sol. alcohol, insol. ether. The aqueous solution crystallises on addition of  $\text{KOH}$  in which it is but slightly soluble. It is not decomposed by  $\text{KOH}$ .— $(\text{PEt}_2)_2\text{ZnI}_2$ : crystals; formed by heating crystallised phosphide of zinc with  $\text{EtI}$  at  $175^\circ$  (Cahours, *A.* 112, 228; 122, 192).— $\text{PEt}_2\text{I}_2$ : [67?]; brown plates (Jørgensen, *Z.* 1871, 770).— $\text{PEt}_2\text{ITl}_2$  (Jørgensen, *J. pr.* [2] 6, 82).— $(\text{PEt}_2)_2\cdot 2\text{BiCl}_3$ .— $(\text{PEt}_2)_2\cdot 2\text{BiI}_3$ : brick-red crystals (J.). The acetate is resolved by heat into  $\text{PEt}_2\text{O}$ , methyl ethyl ketone,  $\text{C}_2\text{H}_4$ ,  $\text{CH}_4$ , and  $\text{CO}$ . The benzoate is resolved by heat into  $\text{PEt}_2\text{O}$ , phenyl ethyl ketone, and benzene (Letts & Collie).

#### Tri-ethyl-phosphine methylo-iodide

$\text{PEt}_2\text{MeI}$ . From  $\text{PEt}_2$  and  $\text{MeI}$ . Gives rise to  $\text{PEt}_2\text{MeOH}$ , to  $(\text{PEt}_2\text{MeCl})_2\text{PtCl}_2$ , and also to  $\text{PEt}_2\text{MeCl}$  which decomposes above  $300^\circ$  into ethylene and  $\text{PEt}_2\text{MeHCl}$  (Collie, *C. J.* 53, 714).

**Tri-ethyl-phosphine chloro-methylo-chloride**  $\text{Et}_2\text{P}(\text{CH}_2\text{Cl})\text{Cl}$ . Formed by treating  $\text{PEt}_2$  (1 mol.) with methylene chloride (1 mol.). Further treatment with  $\text{PEt}_2$  gives  $\text{CH}_3(\text{PEt}_2)_2\text{Cl}$ , which is decomposed by water into  $\text{PEt}_2\text{MeCl}$  and  $\text{PEt}_2\text{O}$  (Hofmann, *Pr.* 11, 290).

**Tri-ethyl-phosphine iodo-methylo-iodide**  $\text{Et}_2\text{P}(\text{CH}_2\text{I})\text{I}$ . Formed in like manner from  $\text{PEt}_2$  and methylene iodide (Hofmann, *Pr.* 10, 618). Moist  $\text{Ag}_2\text{O}$  gives  $\text{Et}_2\text{P}(\text{CH}_2\text{I})\text{OH}$  whence  $(\text{Et}_2\text{P}(\text{CH}_2\text{I})\text{Cl})_2\text{PtCl}_2$ .

**Tri-ethyl-phosphine allylo-iodide**  $\text{PEt}_2\text{C}_2\text{H}_4\text{I}$ . From  $\text{PEt}_2$  and allyl iodide (Hofmann, *Tr.* 1860, 442). Splendid needles. Successive treatment with moist  $\text{Ag}_2\text{O}$  and hydrogen sulphocyanide gives  $\text{PEt}_2\text{C}_2\text{H}_4\text{SCy}$  which crystallises with difficulty.

**Tri-ethyl-phosphine propylo-chloride**  $\text{PEt}_2\text{PrCl}$ . Split up by heat into  $\text{Et}_2\text{PrPCl}$  and ethylene (Collie, *C. J.* 53, 714).

**Tri-ethyl-phosphine isamyl-iodide**  $\text{PEt}_2\text{C}_5\text{H}_{11}\text{I}$ . From  $\text{PEt}_2$  and isamyl iodide

in ethereal solution. Purified by solution in alcohol and ppn. by ether. Gives with moist  $\text{Ag}_2\text{O}$  a hydroxide which on distillation appears to give ethane and di-ethyl-amyl-phosphine oxide. With  $\text{HCl}$  and  $\text{PtCl}_2$  the hydroxide gives prisms of  $(\text{PEt}_2\text{C}_5\text{H}_{11}\text{Cl})_2\text{PtCl}_2$ , sl. sol. water, insol. alcohol, and ether.

**Benzyl-chloride**  $\text{PEt}_2\text{C}_6\text{H}_5\text{Cl}$ . [178?]. Needles. Formed by heating  $\text{PEt}_2$  with benzyl chloride at  $130^\circ$  in presence of alcohol. Above  $300^\circ$  it splits up into  $\text{C}_6\text{H}_5\text{PEt}_2\text{HCl}$  and  $\text{C}_6\text{H}_5$  (Collie, *C. J.* 53, 714). The benzyl-di-ethyl-phosphine  $\text{C}_6\text{H}_5\text{PEt}_2$ , so obtained boils about  $253^\circ$  and forms a crystalline oxide  $\text{C}_6\text{H}_5\text{PEt}_2\text{O}$  [ $330^\circ$ ] and sulphide  $\text{C}_6\text{H}_5\text{PEt}_2\text{S}$  [ $95^\circ$ ] ( $300^\circ$ – $310^\circ$ ). By treatment of  $\text{PEt}_2\text{C}_6\text{H}_5\text{Cl}$  with  $\text{Ag}_2\text{O}$ , a strongly alkaline solution of  $\text{PEt}_2\text{C}_6\text{H}_5(\text{OH})$  is obtained. This base gives a very deliquescent crystalline iodide and a sparingly soluble platinum chloride  $(\text{PEt}_2\text{C}_6\text{H}_5\text{Cl})_2\text{PtCl}_2$ . The base  $\text{PEt}_2\text{C}_6\text{H}_5(\text{OH})$  is split up by heat into toluene and  $\text{PEt}_2\text{O}$  (Collie, *P. M.* 24, 27). The hydroxide does not form a normal carbonate, but it forms an acid carbonate which is split up by heat into toluene  $\text{CO}_2$  and  $\text{PEt}_2\text{O}$ . The sulphate on distillation gives  $\text{PEt}_2\text{O}$ ,  $\text{SO}_2$ , and  $\text{PhCH}_2\text{CH}_2\text{Ph}$ . The bromide gives on distillation  $\text{HBr}$ ,  $\text{PEt}_2\text{HBr}$ ,  $\text{PEt}_2\text{C}_6\text{H}_5\text{HBr}$ , acetylene, &c. The acetate gives  $\text{PEt}_2\text{O}$ , methyl benzyl ketone,  $\text{PEt}_2$ , and benzyl acetate. The oxalate gives  $\text{PEt}_2\text{O}$ , toluene,  $\text{CO}_2$ , and  $\text{CO}$ .

**Tri-ethyl-phosphine bromo-ethylo-bromide**  $\text{Et}_2\text{P}(\text{CH}_2\text{CH}_2\text{Br})_2\text{Br}$ . [235?]. Produced, together with  $\text{C}_2\text{H}_4(\text{PEt}_2)_2$ , by adding ethylene bromide to  $\text{PEt}_2$  mixed with twice its volume of ether until the liquid no longer gives with  $\text{CS}_2$  the red crystals of  $\text{PEt}_2\text{CS}_2$ . The two products are separated by crystallisation from alcohol in which  $\text{C}_2\text{H}_4(\text{PEt}_2)_2$  is much the more soluble. White unctuous elongated rhombic dodecahedra; v. sol. water, m. sol. alcohol. It gives off  $\text{HBr}$  when heated.

**Reactions.**—1. Silver salts added to its cold solution throw down only half the bromine as  $\text{AgBr}$ ; on continued boiling the whole of the bromine is ppd. with formation of salts of vinyl-tri-ethyl-phosphonium.—2. Moist  $\text{Ag}_2\text{O}$  forms a solution of  $\text{Et}_2\text{P}(\text{C}_2\text{H}_5\text{OH})(\text{OH})$ .—3. Potash has no action in the cold.—4. Zinc, and dilute  $\text{H}_2\text{SO}_4$  form  $\text{PEt}_2\text{Br}$ .—5. It unites with  $\text{PMe}_3$  forming  $\text{C}_2\text{H}_5(\text{PEt}_2\text{Br})(\text{PMe}_3)_2$ .—6.  $\text{PEt}_2$  gives  $\text{C}_2\text{H}_5(\text{PEt}_2\text{Br})_2$ .—7. Ammonia gives rise to  $\text{C}_2\text{H}_5(\text{PEt}_2\text{Br})(\text{NH}_2\text{Br})$ ; ethylamine, diethylamine, and trimethylamine act in like manner.—8. Triethylamine when pure has no action at  $100^\circ$ ; but in presence of moist alcohol it forms  $\text{PEt}_2(\text{C}_2\text{H}_5\text{OH})\text{Br}$  and  $\text{NEt}_3\text{HBr}$ .

**Tri-ethyl-phosphine bromo-ethylo-chloride**  $\text{Et}_2\text{P}(\text{CH}_2\text{CH}_2\text{Br})\text{Cl}$ . From the preceding and  $\text{AgCl}$ . Crystallises with difficulty, v. sol. water and alcohol.  $\text{Et}_2\text{P}(\text{C}_2\text{H}_5\text{Br})\text{ClAuCl}_2$ : light yellow needles (from boiling water; sl. sol. cold water).— $\{\text{Et}_2\text{P}(\text{C}_2\text{H}_5\text{Br})\}_2\text{PtCl}_2$ : long monoclinic orange-yellow prisms;  $a:b:c = .969:1:658$ . May be recrystallised from boiling water.

**Tri-ethyl-phosphine bromo-ethylo-iodide**  $\text{Et}_2\text{P}(\text{CH}_2\text{CH}_2\text{Br})\text{I}$ . Scales, sl. sol. cold water. Obtained by decomposing the sulphate by  $\text{BaI}_2$ . The sulphate obtained from the bromide by  $\text{Ag}_2\text{SO}_4$  forms long white needles. The

Moist  $\text{Ag}_2\text{O}$  forms  $\text{PEt}_2\text{Me}(\text{OH})$  and  $\text{PEt}_2\text{O}$  (Hofmann, *Pr.* 10, 189; 11, 290).—14. *Chloroform* or  $\text{CCl}_4$  give  $\text{CH}(\text{PEt}_2)_2\text{Cl}$ .—15. By dropping  $\text{PEt}_2$  upon cooled *chloro-acetic acid* in a vessel full of hydrogen there is formed  $\text{Et}_2\text{P}(\text{CH}_2)_2\text{CO}_2\text{H}$  'the hydrochloride of phosphorus betaine' (Letts, *Tr. E.* 30, 285; *Pr. E.* 11, 40). This compound crystallises from ether in colourless needles, it has an acid reaction, and its platinochloride forms thick light orange needles. The compound  $\text{Et}_2\text{P}(\text{CH}_2)_2\text{CO}_2\text{H}$  splits up at  $145^\circ$  into  $\text{CO}_2$  and  $\text{PEt}_2\text{MeCl}$ . Solid  $\text{KOH}$  gives  $\text{PEt}_2\text{O}$  and potassium acetate. Moist  $\text{Ag}_2\text{O}$  forms  $\text{Et}_2\text{P}(\text{OH})\text{CH}_2\text{CO}_2\text{H}$  which, when dried over  $\text{P}_2\text{O}_5$  in *vacuo*, becomes  $\text{Et}_2\text{P}(\text{O})\text{CH}_2\text{CO}_2\text{H}$ , a very deliquescent neutral substance.  $\text{HBr}$  converts it into  $\text{Et}_2\text{PBrCH}_2\text{CO}_2\text{H}$ , which forms dimetric plates (from alcohol and ether). It is split up by heat into  $\text{CO}_2$  and  $\text{PEt}_2\text{MeBr}$ .  $\text{HI}$  converts  $\text{Et}_2\text{P}(\text{OH})\text{CH}_2\text{CO}_2\text{H}$  into very deliquescent granular crystals of the acid  $\text{Et}_2\text{P}(\text{CH}_2)_2\text{CO}_2\text{H}$ .  $\text{PEt}_2\text{ClCH}_2\text{CO}_2\text{H}$  is converted by  $\text{Ag}_2\text{SO}_4$  into a very deliquescent sulphate which is split up by heat into  $\text{CO}_2$  and  $(\text{PEt}_2\text{Me})_2\text{SO}_4$ .—16.  $\text{PEt}_2$ , mixed with an equimolecular quantity of cooled *chloro-acetic ether* forms very deliquescent  $\text{PEt}_2\text{ClCH}_2\text{CO}_2\text{Et}$  which melts below  $100^\circ$ , and at a higher temperature is split up into  $\text{PEt}_2\text{MeCl}$ ,  $\text{CO}_2$ , and ethylene. It forms a crystalline platinochloride, and is converted by moist  $\text{Ag}_2\text{O}$  into  $\text{Et}_2\text{P}(\text{O})\text{CH}_2\text{CO}_2\text{Et}$ , alcohol,  $\text{PEt}_2\text{O}$ , and acetic ether. Solid  $\text{KOH}$  forms  $\text{PEt}_2\text{O}$ , acetic ether, and  $\text{KCl}$  (Letts, *Tr. E.* 30, 285).—17. *Bromo-acetic ether* forms in like manner an extremely deliquescent compound which melts below  $100^\circ$ , and is split up by heat into  $\text{PEt}_2\text{MeBr}$ ,  $\text{CO}_2$ , and ethylene (Letts).—18. *Bromo-acetic acid* forms a colourless liquid which if heated to  $100^\circ$  and allowed to cool solidifies. The product consists of at least two substances: one of these substances,  $(\text{PEt}_2\text{BrO.CO.CH}_2)_2$ , when treated with potash yields  $\text{PEt}_2\text{O}$  and  $\text{KOAc}$ ; the other, which is perhaps  $\text{PEt}_2\text{H.O.CO.CH}_2\text{Br}$ , yields  $\text{PEt}_2$  with  $\text{KOH}$ . The first compound is also formed when  $\text{PEt}_2\text{O}$  is treated with acetyl bromide (Letts, *Tr. E.* 30, 285).

**Salts.**—The hydrochloride, hydrobromide, hydroiodide, sulphate, and nitrate are crystalline but extremely deliquescent.— $(\text{PEt}_2\text{HI})_2\text{ZnI}_2$ : tablets.— $(\text{PEt}_2)_2\text{H}_2\text{PtCl}_6$ : crystalline, sl. sol. cold water, insol. alcohol and ether. By boiling  $\text{PEt}_2$  with aqueous platinic chloride there are formed two isomeric compounds of the formula  $(\text{PEt}_2)_2\text{PtCl}_4$ , a white substance insol. ether, and a yellow substance crystallising from ether in prisms [ $150^\circ$ ]. The yellow substance is insol. water, and is converted into its isomeride by heating with alcohol at  $100^\circ$ . When boiled with water and  $\text{PEt}_2$ , it forms  $(\text{PEt}_2)_2\text{PtCl}_2$  (Cahours a. Gal, *Z.* 1870, 350, 437).— $(\text{PEt}_2)_2\text{PdCl}_2$ .— $(\text{PEt}_2)_2\text{PtCl}_2$ .— $(\text{PEt}_2)_2\text{PtCl}_2\text{AuCl}_2$ .— $(\text{PEt}_2)_2\text{AuCl}_2$ .

**Tri-ethyl-phosphine oxide**  $\text{PEt}_2\text{O}$ . Mol. w. 134. [ $44^\circ$ ] (H.); [ $58^\circ$ ] (P.). ( $243^\circ$  uncor.). V.D. 4.60 (calc. 4.66).

**Formation.**—1. From  $\text{PEt}_2$  by atmospheric oxidation or by gently heating it with  $\text{HgO}$  or  $\text{Ag}_2\text{O}$  (Cahours a. Hofmann, *A.* 104, 18).—2. By distilling  $\text{PEt}_2\text{OH}$ , the other product being

ethane.—3. By decomposing  $(\text{PEt}_2\text{Cl})_2\text{ZnCl}_2$  with solid  $\text{KOH}$  and a little water (Pebal, *A.* 120, 194).—4. From  $\text{EtOPCl}_2$  and  $\text{ZnEt}_2$  (Wichelhaus, *B.* 1, 80).—5. By heating clear phosphorus (1 pt.) with  $\text{EtI}$  (13 pts.) for 24 hours at  $180^\circ$ , and boiling the product with alcohol. The residue is evaporated and distilled with  $\text{KOH}$  (4 pts.) (Crafts a. Silva, *Z.* 1871, 359; cf. Carius, *A.* 136, 187). When  $\text{PI}_3$  (1 mol.) is heated with  $\text{EtI}$  (8 mols.) iodine is given off, and a body is left which when treated with solid  $\text{KOH}$  yields  $\text{PEt}_2\text{O}$  on distillation (Emmerton, *Am.* 4, 9).

**Properties.**—Slender white deliquescent needles. Dissolves in all proportions in water and alcohol, less sol. ether. Very slightly volatile with steam. Separates as a liquid when solid  $\text{KOH}$  is added to its aqueous solution, or when ether is added to its alcoholic solution. Converted by  $\text{HBr}$  into  $\text{PEt}_2\text{Br}$ , and by  $\text{HI}$  into  $\text{PEt}_2\text{I}$ . It is not affected by  $\text{H}_2\text{S}$  or by halogens. It forms crystalline compounds with some metallic salts:  $(\text{PEt}_2\text{O})_2\text{CuSO}_4$ : deliquescent, four-sided, green prisms (Pebal).— $(\text{PEt}_2\text{O})_2\text{ZnI}_2$ : [ $99^\circ$ ]; crystalline pp. which, when crystallised from alcohol, forms monoclinic crystals;  $a:b:c = .905:1:331$ ;  $\beta = 83^\circ 13'$ .

**Tri-ethyl-phosphine oxy-chloride**  $(\text{PEt}_2)_2\text{OCl}_2$ . By passing dry  $\text{HCl}$  over fused  $\text{PEt}_2\text{O}$  shining crystals are formed, which are dissolved in  $\text{HClAq}$  and the solution is then evaporated (Hofmann). Very deliquescent crystalline mass, sol. water and alcohol, insol. ether. The solution treated with platinic chloride in saturated alcoholic solution yields  $(\text{PEt}_2\text{O})_2\text{PtCl}_4$ , which crystallises from alcohol in large orange monoclinic prisms;  $a:b:c = .631:1:1578$ ;  $\beta = 73^\circ 42'$  (Hofmann, *Tr.* 1860, 419).— $(\text{PEt}_2)_2\text{OCl}_2\text{ZnCl}_2$ : transparent octahedra, sol. water and alcohol. By the action of  $\text{HCl}$  on  $\text{PEt}_2\text{O}$  Crafts a. Silva obtained a compound  $\text{PEt}_2(\text{OH})\text{Cl}$  [ $128^\circ$ ].

**Tri-ethyl-phosphine sulphide**  $\text{PEt}_2\text{S}$ . [ $94^\circ$ ].

**Formation.**—1. By adding flowers of sulphur to an ethereal solution of  $\text{PEt}_2$ , after evaporating the ether the residue is heated with boiling water which dissolves  $\text{PEt}_2\text{S}$  only, depositing it in crystals on cooling.—2. By distilling  $\text{PEt}_2$  with cinnabar.—4. By decomposing  $\text{PEt}_2\text{CS}_2$  with water or  $\text{Ag}_2\text{O}$ .—5. By the action of mercaptan on  $\text{PEt}_2$  in presence of air.

**Properties.**—Long hexagonal needles (from water);  $a:c = 1:821$ . Sol. water, v. sol. alcohol and ether, v. e. sol.  $\text{CS}_2$ . Volatile with steam. Decomposed by sodium giving  $\text{Na}_2\text{S}$  and  $\text{PEt}_2$ . It may be separated from its aqueous solution by  $\text{KOH}$ . Its aqueous solution is neutral to litmus, but it dissolves more readily in  $\text{HClAq}$  than in water, and the solution gives an unstable yellow pp. with platinic chloride. The aqueous solution is not affected by boiling aqueous lead acetate or  $\text{AgNO}_3$ , or by  $\text{HgO}$ , but these substances become sulphides when added to its alcoholic solution.

**Tri-ethyl-phosphine selenide**  $\text{PEt}_2\text{Se}$ . [ $112^\circ$ ]. From  $\text{PEt}_2$  and selenium. Crystallises from water, but turns red if air.

**Tetra-ethyl-phosphonium compounds.**

$\text{PEt}_2(\text{OH})$ . When  $\text{PEt}_2\text{I}$  is digested with water and  $\text{Ag}_2\text{O}$  there is formed a strongly alkaline bitter solution, which dries up over  $\text{H}_2\text{SO}_4$  to an extremely deliquescent crystalline mass. This solid hydroxide absorbs  $\text{CO}_2$  with avidity. Its solution behaves like  $\text{KOH}$  towards solutions of me-

$\text{H}_2\text{PO}_3$ .—2. Bromine gives  $\text{EtBr}$  and  $\text{POCl}_2\text{Br}$ .—3.  $\text{Et}_4\text{PO}_3$  reacts forming  $\text{Et}_3\text{PO}_3$ , phosphorus, and  $\text{EtCl}$ .—4. Heated to  $165^\circ$  in a sealed tube it is resolved into  $\text{EtCl}$ , free phosphorus,  $\text{PCl}_2$ , and  $\text{P}_2\text{O}_3$ .—5. Heated with  $\text{H}_2\text{PO}_3$ , there is evolved  $\text{EtCl}$  and  $\text{HCl}$ , while free phosphorus and  $\text{H}_2\text{PO}_3$  remain.—6.  $\text{PCl}_2$  does not act on it.—7.  $\text{PCl}_2$  at  $100^\circ$  forms  $\text{POCl}_2$ ,  $\text{PCl}_3$ , and  $\text{EtCl}$  (Geuther, *J.* 1876, 206).—8.  $\text{PBr}_3$  gives  $\text{POBrCl}_2$ ,  $\text{PBr}_3$ , and  $\text{EtBr}$ .

Di-ethyl phosphite ( $\text{EtO}$ ),  $\text{POH}$ . The barium salt  $\text{BaA}'$ , is formed by adding a hot solution of baryta (1 mol.) to  $\text{Et}_2\text{PO}_3$ . It forms a very deliquescent crystalline mass; extremely sol. water, sl. sol. alcohol. It does not decompose at  $108^\circ$ . Aqueous  $\text{K}_2\text{SO}_4$  converts it into the deliquescent salt  $\text{KA}'$ . The free acid has not been isolated.

Chloride ( $\text{EtO}$ ),  $\text{PCl}$ . From alcohol (2 mols.) and  $\text{PCl}_3$  (1 mol.) (Wichelhaus, *A. Suppl.* 6, 264). May be distilled. Chlorine converts it into  $\text{EtCl}$  and ( $\text{EtO}$ ) $\text{POCl}_2$ .

Tri-ethyl phosphite ( $\text{EtO}$ ),  $\text{P}$ . Phosphorous ether. (191°). S.G.  $1.075$ . V.D. (in hydrogen) 5.84 (calc. 5.76).  $\text{PCl}_2$  (1 mol.) diluted with five times its bulk of ether is added by small portions to  $\text{NaOEt}$  (3 mols.). The ether is distilled off, and the residue distilled from an oil-bath at  $200^\circ$ . It is rectified in a current of hydrogen (Raiton, *C. J. 7*, 216). At the same time another body  $\text{P}_2\text{O}_3\text{C}_2\text{H}_5$  is formed ( $157.5^\circ$  cor.). S.G.  $1.960$ . This is best formed from dry  $\text{NaOEt}$  (4 mol.) and  $\text{PCl}_2$  (1 mol.), both in ether (Geuther, *A.* 224, 277). It has a pleasant smell, and when distilled it slowly splits up thus:

$\text{P}_2\text{O}_3\text{C}_2\text{H}_5 = \text{PO}_2\text{Et} + \text{PO}_2\text{Et} + \text{HOEt}$ .  
It is not decomposed by water at  $100^\circ$ .

Properties.—Phosphorous ether has a pleasant odour (G.). It is sol. water, alcohol, and ether, and burns with a bluish flame.

Reactions.—1. Heated with baryta-water it gives  $\text{Ba}(\text{Et}_2\text{PO}_3)_2$  and  $\text{BaEt}_2\text{PO}_3$ .—2. Caustic potash gives phosphorous acid and alcohol.—3. Gradual oxidation by nitric acid gives phosphoric and oxalic acids.—4. It absorbs oxygen, especially on warming, forming  $\text{Et}_4\text{PO}_3$ .—5. On distillation it gives  $\text{PH}_3$ , phosphoric acid, and probably ethylene.—6.  $\text{PCl}_2$  gives  $\text{EtOPCl}_2$ ; a smaller quantity of  $\text{PCl}_2$  gives  $\text{Et}_2\text{PO}_3$ , phosphorus, and  $\text{EtCl}$ .—7.  $\text{PCl}_2$  gives ( $\text{EtO}$ ) $\text{POCl}_2$ ,  $\text{EtCl}$ , and  $\text{PCl}_2$  (Chambon).—8. Bromine forms  $\text{EtBr}$  and ( $\text{EtO}$ ) $\text{POBr}$ .

Combination.— $\text{Et}_2\text{PO}_3\text{PtCl}_2$ . [ $83^\circ$ ]. Formed from  $\text{PCl}_2$ , alcohol, and  $\text{PtCl}_2$  (Schützenberger, *Bk.* [2] 18, 101). Yellow prisms. Its ethereal solution absorbs ethylene forming oily ( $\text{Et}_2\text{PO}_3\text{PtCl}_2$ ),  $\text{C}_2\text{H}_4$ .  $\text{CO}$  forms in like manner ( $\text{Et}_2\text{PO}_3\text{PtCl}_2$ ),  $\text{CO}$ . Ammonia passed into the ethereal solution of  $\text{Et}_2\text{PO}_3\text{PtCl}_2$  ppts. colourless crystals of  $\text{Et}_2\text{PO}_3\text{PtCl}_2\text{N}_3\text{H}_4$ . The following compounds of ethyl phosphite have also been described ( $\text{Et}_2\text{PO}_3$ ),  $\text{PtCl}_2$ : prisms.— $\text{Et}_2\text{PO}_3\text{PtCl}_2\text{PtCl}_2$ .—( $\text{Et}_2\text{PO}_3$ ),  $\text{PtCl}_2\text{N}_3\text{H}_4$ .— $\text{Et}_2\text{PO}_3\text{PtCl}_2\text{Br}$ .—( $\text{Et}_2\text{PO}_3$ ),  $\text{PtCl}_2\text{Br}$ .— $\text{Et}_2\text{PO}_3\text{PtCl}_2\text{Cl}$  (Cochin, *Bk.* [2] 31, 499).— $\text{Et}_2\text{PO}_3\text{PtCl}_2$  (Pomey, *Bk.* [2] 35, 421).

TRI-ETHYL-PHOSPHOBETAINE v. TRI-ETHYL-PHOSPHINE, Reactions 12 to 15.

ETHYL-PHOSPHOR-DICHLORIDE is ETHYL-di-chloro-phosphine.

ETHYL-PHOSPHORIC ACID v. ETHYL-PHOSPHATE.

ETHYL-PHOSPHOROUS ACID v. ETHYL-PHOSPHITES.

DI-ETHYL-PHTHALIDE  $\text{C}_8\text{H}_6\langle\text{C}_2\text{H}_5\text{CO}\rangle$

[52°]. Formed by adding  $\text{ZnEt}_2$  to phthalyl chloride mixed with benzene (Wischin, *A.* 143, 260; Friedländer, *Z. K.* 6, 590; V. Meyer, *B.* 17, 318). Large dimetric crystals (from ether). Insol. water, v. e. sol. alcohol and ether. Does not react with  $\text{KHSO}_4$  or hydroxylamine.

ETHYL-PHTHALIMIDE v. Ethylimide of PHTHALIC ACID.

ETHYL-PHTHALIMIDYL-BENZYL is described as BENZYLIDENE-PHTHALETHYLIMIDINE.

$\alpha$ -ETHYL-HOMO- $\alpha$ -PHTHALONITRILE v.  $\alpha$ -CYANO-PHTENYL-BUTYRONITRILE.

ETHYL-PIRAMIDE v. TRI-NITRO-ETHYL-ANTHINE.

ETHYL-PIPERIDINE v. ETHYL-PIRIDINE HEXAHYDRIDE.

ETHYL-PROPARGYL OXIDE v. PROPARGYL ALCOHOL.

ETHYL-ISO-PROPENYL-OXIDE  $\text{C}_5\text{H}_8\text{O}$  i.e.  $\text{Et.O.C}_3\text{H}_5$ , ( $63^\circ$ ). S.G.  $2.79$ ;  $2.769$ . Formed by heating propylene bromide and alcoholic potash in sealed tubes to  $170^\circ$  or by treating propylene  $\text{Me.C}=\text{CH}$  in the same way (Faworsky, *J. pr.* [2] 37, 533). Colourless mobile liquid. Yields on decomposition with dil.  $\text{H}_2\text{SO}_4$  ethyl alcohol and acetone.

ETHYL-PROPIONYL-PROPIONIC ACID.

Methyl ether  $\text{C}_5\text{H}_{10}\text{O}_2$  i.e.

$\text{CH}_3\text{CH}_2\text{CO.CMeEt.CO.Me}$ .

( $208^\circ$ ). From methyl-propionyl-propionate,  $\text{EtI}$ , and  $\text{NaOEt}$  at  $100^\circ$  (Fingel, *A.* 245, 84).

ETHYL-PROPIONYL-UREA v. Propionyl derivative of ETHYL-UREA.

ETHYL-PROPYL ACETAL. Described under ALDEHYDE.

ETHYL-PROPYL-ACETIC ACID v. HEPTOIC ACID.

ETHYL-PROPYL-ACETYLENE v. HEPTINENE.

DIETHYL-PROPYL-ALKINE v. DI-ETHYL-OXYPROPYL-AMINE.

TRI-ETHYL-PROPYL-AMMONIUM IODIDE  $\text{C}_8\text{H}_{17}\text{NI}$  i.e.  $\text{NEt}_3\text{PrI}$ . From  $\text{NEt}_3$  and  $\text{PrI}$  (Mendius, *A.* 121, 136). Needles.— $\text{B}_2\text{H}_6\text{PtCl}_2$ : octahedra.

ETHYL-PROPYL-ANILINE  $\text{C}_8\text{H}_9\text{NEtPr}$ . [ $216^\circ$  uncor.] Liquid. Formed by the action of ethyl bromide upon propyl-aniline, or of propyl bromide upon ethyl-aniline.— $\text{B}^{\text{HCl}}$ : crystals, [ $181^\circ$  uncor.] (Claus, *A.* Hirzel, *B.* 19, 2787).

Methylo-iodide v. Propylo-iodide of METHYL-ETHYL-ANTHINE.

ETHYL-PROPYL-BENZENE

[ $81^\circ$ ]  $\text{C}_8\text{H}_{10}$  ( $\text{C}_2\text{H}_5$ ) $\text{Et}$ . (194°). S.G.  $1.8588$ . V.D. 5.87. Occurs in resin oil (Renard, *C. R.* 97, 328). Gives isophthalic acid on oxidation.  $\text{H}_2\text{SO}_4$  gives a sulphonic acid of which the  $\text{Ba}$  salt ( $\text{C}_8\text{H}_7\text{SO}_3$ ),  $\text{Ba}$  as crystallises in plates.

ETHYL-PROPYL-CARBINOL v. ETHYL ALCOHOL.

Ethyl-di-propyl-carbinol v. ENNYL ALCOHOL.

ETHYL-PROPYL-CARBONATE

( $\text{C}_2\text{H}_5\text{O}$ ),  $\text{CO}$ , ( $\text{OOH}$ ). ( $146^\circ$  cor.). S.G.  $2.9516$ . Colourless liquid. Formed by adding  $\text{AlCl}_3$  to a mixture of propyl alcohol and ethyl chloroformate (Pawlewski, *B.* 17, 1806).

ETHYL-PROPYLENE v. ANYLENE.

**ETHYL PROPYL ETHER v. ETHYL PROPYL OXIDE.**

**DI-ETHYL-PROPYL-GLYCOLLINE v. DI-ETHYL-DI-OXYPROPYL-AMINE.**

**ETHYL-PROPYL-GLYOXALINE**

$C_6H_5(C_2H_5)(C_3H_7)N_2$ . Oxal-propylamine. (231°). S.G. 1.962. V.D. 4.8 (obs.).

**Formation.**—1. From di-propyl-oxamide by the action of  $PCl_5$ , the resulting chloro-ethyl-propyl-glyoxaline (v. p. 66) being reduced by HI and phosphorus (Wallach, A. 214, 314; B. 14, 423).—2. By the action of propyl bromide on secondary (para)-ethyl-glyoxaline  $B_2H_4ClPtCl$  (Wallach, B. 16, 543; Radziszewski, B. 16, 491).

**Properties.**—Liquid, with narcotic smell; miscible with water. Its zinc-double salt distilled with lime yields  $NH_3$ , an olefine, pyrrol, and a basic liquid (c. 253°).

**Salts.**— $B_2H_4PtCl_2$ : orange laminae. —  $B_2H_4ZnCl_2$ : [92°]; prisms.

**Methylo-compounds**  $BMeI$ : needles, sol. water. —  $B_2MePtCl_2$ : plates.

**Ethyl-isopropyl-glyoxaline**  $C_6H_5(C_2H_5)N_2$ . Oxal-ethyl-butylamine. (220°). S.G. 1.959 (Rieser, M. 9, 607).

**DI-ETHYL-PROPYLIDENE DISULPHONE**  $CM_2(SO_2Et)_2$ . Sulfonal. Di-ethyl-sulphone-di-methyl-methane. Propane disulphinic ether. [126°]. (c. 300°). S. l in the cold; 5 at 100°.

**Preparation.**—1. By action of sodium on a benzene solution of ethylidene-di-ethyl-sulphone previously mixed with methyl iodide.—2. By boiling an alcoholic solution of ethylidene-di-ethyl-sulphone with methyl iodide and alcoholic potash.—3. By treating  $EtS_2SO_3OH$  with acetone and HCl, the product  $CM_2(S_2Et)_2$  being oxidised by  $KMnO_4$  (Baumann, B. 19, 2808).

**Properties.**—Thick prisms; sl. sol. cold water and alcohol; m. sol. hot water. Used as a soporific, being said to have no concomitant effects. Does not evolve hydrogen when sodium is added to its benzene solution (E. Fromm, B. 21, 187).

**ETHYL n-PROPYL KETONE**  $C_6H_5O$  i.e.  $Et.CO.Pr$ . Mol. w. 100. (c. 123°). S.G. 1.23818.

**Formation.**—1. Occurs among the products of the distillation of calcium butyrate (Friedel, A. 108, 125).—2. From butyryl chloride and  $ZnEt_2$ , followed by water (Butlerow, Bl. [2] 5, 17). 3. By distilling a mixture of calcium propionate and calcium butyrate (Völker, B. 8, 1019).

**Properties.**—Liquid. Does not unite with  $NaHSO_4$  in the cold, but on heating the mixture and allowing it to cool a crystalline compound is formed, which is resolved by water into its constituents. Chromic acid mixture gives only propionic acid according to Popoff (A. 161, 285), but Wagner (J. R. 16, 660) obtained acetic and butyric acids also. Sodium amalgam reduces it to a secondary hexyl alcohol and a pinacone  $C_{12}H_{24}O_2$ . Zinc and  $MeI$  forms  $CM_2EtPrOH$  (140°) (Sokoloff, J. R. 1887, 587).

**Ethyl isopropyl ketone**  $Et.CO.Pr$ . (118°) (P.); (114°) at 745 mm. (W.). S.G. 0.880; 0.814 (W.). From isobutyryl chloride and  $ZnEt_2$  (Butlerow, A. 189, 44; Pawloff, J. R. 8, 242; Wagner, J. R. 16, 697). Liquid. Does not combine with  $NaHSO_4$ . Gives, on oxidation by chromic acid, propionic, acetic, and isobutyric acids (W.).

**ETHYL PROPYL OXIDE**  $C_6H_5O$  i.e.  $Et.O.Pr$ .

(68-6°). S.G. 0.7645 (Dobner, A. 248, 4); 0.7386 (Brühl, A. 200, 177). S.V. 127.1. C.E. (0°-10°) 0.0134 (D.).  $\mu_s$  1.3740 (B.). R. 42-86 (B.). Critical temperature 233° (Pawlewsky, B. 16, 2634). Formed by distilling a mixture of ethyl alcohol and propyl alcohol with  $H_2SO_4$ ;  $Et.O$  being also formed (Norton, A. Prescott, Am. 6, 245). Also from n-propyl bromide and  $NaOEt$  in alcohol, much propylene being given off.

**Ethyl isopropyl oxide**  $Et.O.Pr$ . (64°) (Markownikoff, A. 138, 374); (48°) (R.). S.G. 0.745 (M.). Formed by heating isopropyl iodide (1 vol.), triethylamine (2 vols.), and alcohol (4 vols.) at 150° (Reboul, J. 1881, 409). Dilute  $H_2SO_4$  at 150° splits it up into  $EtOH$  and isopropyl alcohol (Eltakoff, Bn. 1, 298).

**DI-ETHYL-PROPYL-PHOSPHINE**  $PEt_2.Pr$ . (146°-149°). From  $PEt_2PrCl$ , by distilling and treating the product with  $NaOHAq$  (Collie, C. J. 53, 721).

**ETHYL-PROPYL-PINACONE v. DI-OXYDODECANE.**

(Py. 2:3) **ETHYL-PROPYL-QUINOLINE**

$C_6H_5 \begin{array}{c} \text{CH} \cdot \text{C}(C_2H_5) \\ | \\ \text{N} : \text{C}(C_2H_5) \end{array}$  (291° at 720 mm.). Pre-

pared by slowly adding n-butyric aldehyde (100 g.) to a cooled mixture of aniline (60 g.) and fuming HCl (120 g.). Colourless liquid. Volatile with steam. V. sol. alcohol, ether, &c., nearly insol. water. On oxidation with  $CrO_3$  it gives (Py. 2)-ethyl-quinoline-(Py. 3)-carboxylic acid.

**Salts.**— $BHCl2aq$ : flat triclinic tables. —  $BHNO_3aq$ : long white needles. —  $BHSO_4$ : easily soluble concentric needles. —  $B_2H_4ClPtCl_2$ : yellow needles, sol. hot, insol. cold, water. —  $B_2H_4CrO_3$ : long orange-yellow needles. —  $B_2C_2H_4(NO_3)_2OH$ : [163°]; glistening yellow plates or needles, sol. hot water and hot alcohol, very sparingly sol. cold alcohol, insol. cold water.

**Methylo-iodide**  $BMeIaq$ : [172°]; yellow needles; v. sol. water and alcohol, insol. ether. —  $(BMeCl)_2PtCl_2$ : orange-yellow needles (Kahn, B. 18, 8361).

**ETHYL-PROPYL-DI-THIO-CARBONATE v. ETHYL CARBONATES.**

(v) or (Py. 1)-**ETHYL-PYRIDINE**

$Et.C \begin{array}{c} \text{OH} = \text{CH} \\ > \text{N} \cdot (166^\circ) \\ \text{OH} - \text{CH} \end{array}$  S.G. 0.9522; 0.9358.

**Formation.**—By heating pyridine ethylo-iodide in sealed tubes to 320° and separating the (Py. 3)- and (Py. 1)-isomerides by means of the platino-chlorides or ferrocyanides. The salts of the Py. 1 base are least soluble (Ladenburg, A. 247, 18; cf. B. 16, 2059).

**Properties.**—Unpleasant smelling liquid, sl. sol. water. Yields on oxidation with permanganate isonicotinic acid (308°).

**Salts.**— $(C_5H_5NHCl)_2PtCl_2$ : [208°]; plates, sl. sol. water. —  $B_2H_4AuCl_2$ : [188°]; golden-yellow prisms. — Picrate: [163°]; thin yellow needles. — Mercuric chloride double salt [150°]. According to C. de Coninck this base (or the mixture of isomerides) occurs in coal-tar lutidine (C. R. 98, 235).

(a)- or (Py. 8)-Ethyl-pyridine  
 $\begin{array}{c} \text{CH} \\ \diagup \quad \diagdown \\ \text{CH}=\text{CH} \\ \diagdown \quad \diagup \\ \text{CH}-\text{C}-\text{Et} \end{array} \text{N. (148.5}^\circ \text{ cor.) at 752 mm. S.G. } 2.9498.$

**Preparation.**—3 g. of pyridine are heated for an hour with 6 g. EtI to 320°. Some ethylbenzene is formed. The acid contents of the tube are distilled from a copper retort with steam. The residue is then supersaturated with NaOH aq. and distilled until the distillate is no longer alkaline. The base is then separated by means of solid KOH and fractionated. Purified by means of gold salt, which is decomposed by  $\text{SH}_2$  (Ladenburg, A. 247, 14). (Py. 1)- and (Py. 3)-ethyl pyridines cannot be separated by fractionation.

**Properties.**—Colourless liquid, sl. sol. water, miscible with alcohol. It gives picolinic acid on oxidation.

**Salts.**— $(\text{C}_6\text{H}_5\text{NHCl})_2\text{PtCl}_4$ : [164°]; orange-yellow plates.  $\text{C}_6\text{H}_5\text{N.HClAuCl}_4$ : [121°]; yellow plates, v. sol. water.—Picrate:  $\text{B}^+\text{C}_6\text{H}_5(\text{NO}_2)_3\text{OH}$ . [110°].

(Py. 1,3)-Di-ethyl-pyridine  
 $\begin{array}{c} \text{CH}=\text{C}-\text{Et} \\ \diagup \quad \diagdown \\ \text{EtC} \quad \text{N. (188}^\circ \text{). S.G. } 2.9338. \text{ Is} \\ \text{CH}-\text{CH} \end{array}$   
 formed, together with (Py. 1)- and (Py. 3)-ethyl pyridine by the action of EtI on pyridine (Ladenburg, A. 247, 48). Colourless liquid with a very unpleasant odour, sl. sol. water. It yields lutidinic acid [235°] on oxidation.

**Salts.**— $(\text{C}_6\text{H}_5\text{NHCl})_2\text{PtCl}_4$ : [171°]; orange-yellow prisms, sl. sol. water.—Picrate:  $\text{C}_6\text{H}_5\text{N.C}_6\text{H}_4(\text{NO}_2)_3\text{OH}$ : [100°]; prisms (from water), plates (from alcohol).

(a)- or (Py. 3)-ETHYL-PYRIDINE HEXA-

HYDRIDE  $\begin{array}{c} \text{CH}_2-\text{CH}_2\text{Et} \\ \diagup \quad \diagdown \\ \text{CH}_2-\text{CH}_2 \end{array} \text{NH. Ethyl-piperi-}$

dine. (145°). S.G. 8674. Formed by reducing (Py. 8)-ethyl pyridine with sodium and alcohol (Ladenburg, A. 247, 70; B. 18, 2963). Liquid smelling of pyridine hexahydrate.

**Reactions.**—1. Forms with MeI a  $\nu$ -methyl derivative.—2. Br and NaOH aq. convert it into a base containing 2H less (cf. B. 20, 1645).

**Salts.**— $(\text{C}_6\text{H}_5\text{N.HCl})_2\text{PtCl}_4$ : [178°]; plates m. sol. water.

(7)- or (Py. 1)-Ethyl-pyridine hexahydrate.

$\begin{array}{c} \text{CH}_2-\text{CH}_2 \\ \diagup \quad \diagdown \\ \text{EtCH} \quad \text{NH. (7)-Ethyl-piperidine.} \\ \text{CH}_2-\text{CH}_2 \end{array}$

(168°). S.G. 8759. Formed by reducing (Py. 1)-ethyl pyridine with sodium and absolute alcohol (Ladenburg, A. 247, 72; cf. C. R. 98, 516). Liquid with an unpleasant odour. More soluble in cold than in hot water. Its hydrochloride acts physiologically like coniine (Fleishner, B. 16, 739).

**Salts.**— $(\text{C}_6\text{H}_5\text{NHCl})_2\text{PtCl}_4$ : [174°]; orange-coloured plates, m. sol. water.— $\text{B}^+\text{HClAuCl}_4$ : [105°]; golden-yellow plates sl. sol. cold, v. sol. hot water.

**Methylene-di-iodide**  $\text{C}_6\text{H}_5\text{N}_2$ . Formed by heating ethyl-piperidine with methylene-iodide. It forms sparingly soluble yellow plates.

Only one I atom can be removed by  $\text{Ag}_2\text{O}$ , or replaced by Cl by means of AgCl.

The *chloro-iodide*  $\text{C}_6\text{H}_5\text{N}_2\text{I}_2\text{Cl}$  is formed from the di-iodide by AgCl.— $(\text{C}_6\text{H}_5\text{N}_2\text{I}_2\text{Cl})_2\text{PtCl}_4$ : orange crystals.— $(\text{C}_6\text{H}_5\text{N}_2\text{I}_2\text{Cl})\text{AuCl}_4$ : small yellow crystals (Ladenburg, B. 14, 1843).

(Py. 1,3)-Di-ethyl-pyridine hexahydrate

$\begin{array}{c} \text{CH}_2-\text{CH}_2\text{Et} \\ \diagup \quad \diagdown \\ \text{CH}_2-\text{CH}_2 \end{array} \text{NH. (c. 176}^\circ \text{). S.G. } 2.8722.$

Formed by reducing (Py. 1,3)-di-ethyl-pyridine with sodium and alcohol (Ladenburg, A. 247, 97).— $\text{B}^+\text{H}_2\text{PtCl}_4$ . [174°].

ETHYL-PYRROLE  $\text{C}_6\text{H}_5\text{N}$  i.e.  $\begin{array}{c} \text{CH}=\text{CH} \\ \diagup \quad \diagdown \\ \text{CH}=\text{CH} \end{array} \text{NEt.}$

(131°). S.G. 1.888. Prepared by the action of ethyl iodide on pyrrole potassium. Formed also by distilling neutral ethyl-ammonium mucate or saccharate (C. A. Bell, B. 9, 935; Bell & Lapper, B. 10, 1962; cf. Lubavin, Z. [2] 5, 399). Formed also by distilling ethyl-iso-cinimide with zinc-dust (Bell, B. 13, 878). Colourless liquid; insol. water, miscible with alcohol and ether. Its vapour turns acidified pine-wood red. By long boiling with HCl it gives a red powder of the constitution  $\text{C}_6\text{H}_5\text{N}_2\text{O}$ , [165°–170°]. Potassium does not attack it. Its alcoholic solution gives a pp. with  $\text{HgCl}_2$ .

*Tetra-bromo- derivative*

$\begin{array}{c} \text{CBr}=\text{CBr} \\ \diagup \quad \diagdown \\ \text{CBr}=\text{CBr} \end{array} \text{NEt. [90}^\circ \text{]. Colourless needles. Insol. water, sol. alcohol. Prepared by the action of Br on ethyl-pyrrole (Bell, B. 11, 1810).}$

Ethyl-pyrrole  $\text{C}_6\text{H}_5\text{EtN}$ ? (164°). Formed by adding  $\text{ZnCl}_2$  (12 g.) to a mixture of pyrrole (50 g.) and paraldehyde (50 g.), the reaction beginning at once with evolution of heat (Dennstedt & Zimmermann, B. 19, 2189). Colourless, but turns brown in air. Conc. HCl at 130° appears to give  $\text{CHMe} < \begin{array}{c} \text{CH}-\text{CH} \\ \diagup \quad \diagdown \\ \text{CH}-\text{CH} \end{array} \text{NEt.}$

*Acetyl derivative*  $\text{C}_6\text{H}_5\text{Et.NAc. (225}^\circ \text{). Formed by boiling ethyl-pyrrole with Ac}_2\text{O and NaOAc. An isomeric acetyl derivative [47}^\circ \text{] (250}^\circ \text{) is formed at the same time. Benzoic aldehyde and potash converts the acetyl derivative into } \text{C}_6\text{H}_5\text{Et.N.CO.CH:CHPh [150}^\circ \text{].—C}_6\text{H}_5\text{AgEtNac.}$

ETHYL-PYRROLE-AZO- v. Azo- compounds.

ETHYL-PYRROLE CARBOXYLIC ACID  $\text{C}_6\text{H}_5\text{EtN.CO}_2\text{H. [78}^\circ \text{]. Formed by heating its ethylamide with alcoholic potash at 120}^\circ \text{ (Bell, B. 10, 1864). Slender silky needles (from hot water). Volatile with steam. Above 100}^\circ \text{ it splits up into CO}_2 \text{ and ethyl-pyrrole. Boiling dilute HCl decomposes it in like manner. FeCl}_3 \text{ gives a red colour.—AgA': needles (from hot water).}$

*Ethylamids*  $\text{C}_6\text{H}_5\text{N}_2\text{O}$  i.e.

$\text{C}_6\text{H}_5\text{EtN.CO.NHEt. Di-ethyl-carboxypyrrolamide. [44}^\circ \text{]. (270}^\circ \text{) Formed, together with ethyl-pyrrole and the diethylamide of ethyl-pyrrole di-carboxylic acid by heating ethylamine mucate in a paraffin-bath (Bell). Prisms (from water). Soluble in conc. HCl aq. without change; even boiling aqueous alkalis have little action, but it is saponified by alcoholic KOH at 126°. Bromine water gives a pp. of the tri-bromo-derivative}$

$\text{C}_6\text{H}_7\text{Br}_2\text{N}_2\text{O}$  i.e.  $\begin{array}{c} \text{CO.NHEt} \\ \text{CBr:O} \\ \text{CBr:CBr} \end{array} \text{NEt}$  [121°] while  $\text{C}_6\text{H}_7\text{Br}_2\text{N}_2\text{O}_2$  [197°] remains dissolved (Bell, B. 11, 1818).

**Ethyl-pyrrole dicarboxylic acid**  
 $\text{C}_6\text{H}_7\text{EtN}(\text{CO}_2\text{H})_2$ . Obtained by heating its ethylamide with alcoholic potash at 130° (Bell). Needles (from dilute alcohol). Sublimes without melting at 250°, being partly split up into ethylpyrrole and  $\text{CO}_2$ . Slowly split up in like manner by strong acids in the cold.— $\text{Ag}_2\text{A}''$ : insol. water.

**Di-ethyl-di-amide**  $\text{C}_6\text{H}_7\text{EtN}(\text{CONHEt})_2$ . **Tri-ethyl-dicarboxypyrrolamide**. [230°]. Formed in small quantity by distilling ethylamino mucate (Bell). Needles. Insol. water, sol. conc.  $\text{HClAq}$ . May be sublimed. Saponified by alcoholic, but not by aqueous, potash.

**ETHYL-QUINALDINIC ACID** v. **ETHYL-QUINOLINE-(Py. 3)-CARBOXYLIC ACID**.

( $\gamma$ )- or (Py. 2)-**ETHYL-QUINOLINE**

$\text{C}_6\text{H}_7\text{N}$  i.e.  $\text{C}_6\text{H}_7 \begin{array}{c} \text{CH:CEt} \\ \text{N:CH} \end{array}$ . (273° cor.) (Reher,

B. 20, 2734). Colourless refractive liquid. Formed by distillation of its (Py. 3)-carboxylic acid,  $\text{CO}_2$  being evolved (Kahn, B. 18, 3370). Obtained also by reducing (Py. 8, 2)-chloro-ethyl-quinoline with  $\text{HI}$  in acetic acid (Baeyer & Jackson, B. 13, 121); and, together with the following isomeride, by heating quinoline ethyl-iodide at 280° (Reher, B. 19, 2995). Gives cinchoninic acid on oxidation. On reduction it yields a base boiling at (271°-275°).

**Salts**.—The hydrochloride is v. sol. water and deliquescent.— $\text{B}^+\text{HNO}_3$ : [116°]; white needles.— $\text{B}^+\text{HHgCl}_4$ : [154°]; white needles, v. sol. dilute  $\text{HClAq}$ .— $\text{B}^+\text{HAuCl}_4$ : slender yellow needles.—**Chromate**: red needles.— $\text{B}^+\text{H}_2\text{Cl}_2\text{PtCl}_4$ : [203°]; orange-yellow needles.—**Picrate**: [163°] (K.); [178°-186°] (R.); fine yellow needles.—**Zinc double chloride**: [195°]; concentric needles (R.).

**Methylo-iodide**  $\text{B}^+\text{MeI}$ . [149°].

( $\alpha$ )- or (Py. 3)-**Ethyl-quinoline**  $\text{C}_6\text{H}_7\text{NEt}$  i.e.

$\text{C}_6\text{H}_7 \begin{array}{c} \text{CH:CH} \\ \text{N:CEt} \end{array}$ . (258° cor.). Formed by distilling (Py. 3)-ethyl quinoline (Py. 1)-carboxylic acid with 5 times its weight of soda-lime (Döbner, A. 242, 272; Reher, B. 19, 2995; 20, 2734). Formed also by heating quinoline ethyl-iodide (v. supra).

**Properties**.—Colourless hygroscopic oil. \*Sl. sol. water, v. sol. alcohol and ether. Gives quinoline (Py. 3)-carboxylic (quinaldinic) acid on oxidation. May be reduced by tin and  $\text{HCl}$  to a tetrahydride (c. 261°), which forms a crystalline hydrochloride.

**Salts**.—The chloride, nitrate, and sulphate are v. sol. water. The chloride and nitrate are efflorescent. The chromate crystallises in red needles.— $(\text{B}^+\text{HCl})_2\text{PtCl}_4$  2aq: [189°]; orange-red needles or tables, sl. sol. water.— $\text{B}^+\text{HHgCl}_4$ : [118°]; slender needles.— $\text{B}^+\text{HAuCl}_4$ : [142°]; canary-yellow needles.— $\text{B}^+\text{H}_2\text{SnCl}_4$  2aq: crystalline.—**Picrate**  $\text{B}^+\text{C}_6\text{H}_7\text{N}_2\text{O}_7$ : [148°]; lemon-yellow needles (from alcohol) sl. sol. water.

VOL. II.

**Methylo-iodide**  $\text{B}^+\text{MeI}$ : [180°]; greenish-yellow needles (from alcohol).

**Ethyl(?) -isoquinoline**  $\text{C}_{11}\text{H}_{11}\text{N}$  probably  $\text{C}(\text{C}_2\text{H}_5)_2\text{CH} \begin{array}{c} | \\ \text{CH} \end{array} \text{N}$ . [65°]. (275° at 264 mm.).

Crystalline solid. Formed by complete dechlorination of di-chloro-ethyl(?) -isoquinoline by heating with  $\text{HI}$  and  $\text{P}$  at 200°.

**Salts**.— $\text{B}^+\text{H}_2\text{Cl}_2\text{PtCl}_4$  2aq: orange-yellow flat needles.— $\text{B}^+\text{H}_2\text{CrO}_4$ : orange-red glistening needles (Gabriel, B. 20, 1207).

**Di-ethyl-quinoline**  $\text{C}_6\text{H}_7\text{Et}_2\text{N}$ . (284° cor.). Obtained as a by-product in the ethylation of quinoline by heating its ethylo-iodide at 285° (Reher, B. 19, 9995). Liquid, smelling like quinoline. On oxidation with chromic mixture it gives an acid [190°].— $\text{B}^+\text{H}_2\text{PtCl}_4$ : [217°]; orange-red needles, blackens before melting.— $\text{B}^+\text{HHgCl}_4$ : [116°]; needles.

**References**.—BROMO-, CHLORO-, and OXY-ETHYL-QUINOLINE.

(Py. 2)-**ETHYL-QUINOLINE-(Py. 3)-CABB-**

**OXYLIC ACID**  $\text{C}_6\text{H}_7 \begin{array}{c} \text{CH:CEt} \\ \text{N:C(CO}_2\text{H)} \end{array}$ . (Py. 2).

**Ethyl-quinaldinic acid**. [148°]. Glistening needles (containing 1aq). Sol. alcohol and hot water, sl. sol. ether. Formed by oxidation of (Py. 2:3)-ethyl-propyl-quinoline with  $\text{CrO}_3$  and  $\text{H}_2\text{SO}_4$ . On distillation it evolves  $\text{CO}_2$  and gives (Py. 2)-ethyl-quinoline.

**Salts**.— $(\text{A}^+\text{H.HCl})_2\text{PtCl}_4$ : fine needles.—**Picrate**: [158°]; fine yellow needles, sl. sol. water and cold alcohol.— $\text{A}^+\text{Ag}$ : amorphous white pp., or very fine microscopic needles.— $\text{A}^+\text{Cu}$ : bluish-green microcrystalline pp. (Kahn, B. 18, 3368).

(Py. 3:1)-**Ethyl-quinoline carboxylic acid**  $\text{C}_6\text{H}_7\text{NEtCO}_2\text{H}$ . (Py. 3)-**Ethyl-cinchonic acid**. [173°].

**Preparation**.—Pyruvic acid (70 g.) and propionic aldehyde (50 g.) are dissolved in alcohol, and anilin (80 g.) is gradually added, and the mixture heated on the water-bath with an inverted condenser (Döbner, A. 242, 270).

**Properties**.—Needles or plates. V. sol. alcohol, ether and hot water. Yields on heating with soda-lime (Py. 3)-ethyl-quinoline.

**Salts**.—Chloride, nitrate, and sulphate are v. sol. water.— $(\text{B}^+\text{HCl})_2\text{PtCl}_4$  2aq: orange-yellow needles, v. sol. water, sl. sol. alcohol, insol. ether.— $\text{AgA}'$ : pp. v. sl. sol. water.

**ETHYL-QUINOLINE TETRAHYDRIDE**

$\text{C}_6\text{H}_7 \begin{array}{c} \text{CH}_2\text{CH}_2 \\ | \\ \text{NEtCH}_2 \end{array}$  v. **QUINOLINE**. An isomeride is obtained by reducing (Py. 3)-ethyl-quinoline (q. v.).

(Py. 1)-**ETHYL-QUINOLINE SULPHONIC ACID**  $\text{C}_6\text{H}_7\text{EtN.SO}_3\text{H}$ . [above 315°]. Obtained by heating ( $\gamma$ )- or (Py. 1)-ethyl-quinoline with fuming  $\text{H}_2\text{SO}_4$  (10 pts.) at 260° (Reher, B. 19, 2095). Slender needles, insol. alcohol, v. sol. hot water.

**TRI-ETHYL-ROSANILINE** v. **TRI-ETHYL-TRI-AMIDO-DI-PHENYL-TOLYL-CARBINOL**.

**MONO-ETHYL SELENATE**  $\text{EtHSO}_3\text{SeO}_3\text{H}$ . i.e.  $\text{SO}_2(\text{OH})(\text{OEt})$ . An unstable acid obtained by treating selenic acid with alcohol (Fabian, A. L L).

*Suppl.* 1, 244).— $\text{SrA}'_2$ : tables.— $\text{CuA}'_2$  4aq: plates.

**ETHYL SELENHYDRATE**  $\text{EtSeH}$ . (above 100°). A liquid formed according to Wöhler and Siemens (*A.* 61, 860) when  $\text{KSeH}$  is distilled with alcohol. It has a very disgusting odour, and its alcoholic solution gives a yellow pp. with  $\text{HgCl}_2$ .

**ETHYL SELENIDE**  $\text{C}_2\text{H}_5\text{Se}$ , *Sei.e.*  $\text{Et}_2\text{Se}$ . (108°). Prepared by digesting equivalent quantities of  $\text{P}_2\text{Se}_3$  and  $\text{K}_2\text{SO}_4$  with a small quantity of water at 50°, the product being fractionally distilled (Von Pieverling, *A.* 185, 331). Colourless mobile liquid, smelling like a hydrocarbon. Insol. water, miscible with alcohol and ether. Its solution in dilute  $\text{HNO}_3$  gives with  $\text{HCl}$  oily  $\text{Et}_2\text{SeCl}_2$ , whence aqueous ammonia forms crystalline  $(\text{Et}_2\text{Se})_2\text{OCl}_2$  (Joy, *A.* 86, 35).

**Ethyl-iodide**  $\text{SeEt}_2\text{I}$ . *Tri-ethyl-selenium iodide*. Slowly formed by combination of  $\text{SeEt}_2$  with  $\text{EtI}$  in the cold (P.). White crystals, stable in the air, v. e. sol. water and alcohol, sl. sol. ether. Sublimes between 80° and 120°, being split up into  $\text{SeEt}_2$  and  $\text{EtI}$ , which slowly recombine in the cold.

**Ethyl-hydroxide**  $\text{SeEt}_2\text{OH}$ . Formed by treating the ethyl-iodide with moist  $\text{Ag}_2\text{O}$ . Powerful base, forming a syrupy solution which absorbs  $\text{CO}_2$  with avidity. Its salts smell like leeks and, with exception of the tartrate, are very deliquescent.

Acid tartrate  $\text{SeEt}_2\text{C}_4\text{H}_4\text{O}_6$  2aq: pale rose-red needles, v. e. sol. water, forming an acid solution.—Platinochloride  $(\text{SeEt}_2\text{Cl})_2\text{PtCl}_2$ : red rhombohedra. Monoclinic according to Schimper (*Z. K.* 1, 218).—Zinc double chloride  $(\text{SeEt}_2\text{Cl})_2\text{ZnCl}_2$ : from  $\text{SeCl}_4$  and  $\text{ZnEt}_2$  (Rathke, *A.* 152, 210).

**Di-ethyl di-selenide**  $\text{Et}_2\text{Se}_2$ . (186°). From  $\text{K}_2\text{Se}_2\text{O}_8$  and  $\text{K}_2\text{Se}$  (Rathke). Reddish-yellow liquid with highly disgusting smell. Its solution in dilute  $\text{HNO}_3$  gives with  $\text{HCl}$  crystals of  $\text{EtSeO}_2\text{H}_2\text{Cl}$  (?); these are v. sol. water, and are reduced by  $\text{SO}_2$  to  $\text{Et}_2\text{Se}_2$ .

**ETHYL DI-SELENO-PHOSPHATE**  $\text{C}_2\text{H}_5\text{P}_2\text{O}_5\text{Se}$  *i.e.*  $\text{Et}_2\text{P}_2\text{O}_5\text{Se}_2$ . An oil obtained by treating  $\text{P}_2\text{Se}_3$  with alcohol (Carius, *A.* 124, 57). Slowly decomposed by water.

**ETHYL SILICATE**  $\text{Et}_2\text{SiO}_3$ . (350°). *S.G.*  $\frac{22}{1}$  1-079. Formed, according to Ebelmen (*A.* 57, 331), together with  $\text{Et}_2\text{Si}_2\text{O}_5$ , by treating  $\text{SiCl}_4$  with wet alcohol. Slowly saponified by water. Friedel and Crafts (*A. Ch.* [4] 9, 5) could not obtain this ether, but found instead  $\text{Et}_2\text{Si}_2\text{O}_5$  (125°–180° *in vacuo*). *V.D.* 12-03 (calc. 11-86). *S.G.*  $\frac{22}{1}$  1-0196;  $\frac{22}{1}$  1-0119. The ether  $\text{Et}_2\text{Si}_2\text{O}_5$  is also formed by treating  $\text{SiOCl}_2$  with alcohol (Friedel a. Ladenburg, *A.* 147, 362); it is converted by gaseous  $\text{NH}_3$  into  $\text{Et}_2\text{Si}_2\text{O}_5(\text{NH}_2)$  (280° *in vacuo*) and  $\text{Et}_2\text{Si}_2\text{O}_5(\text{NH}_2)_2$  (Troost a. Hautefeuille, *A. Ch.* [5] 7, 472).

**Ethyl ortho-silicate**  $\text{C}_2\text{H}_5\text{SiO}_3$  *i.e.*  $\text{Et}_2\text{SiO}_3$ . *Silicic ether*. (166°). *S.G.*  $\frac{22}{1}$  1-033 (E.); 1-063 (Friedel a. Crafts, *A. Ch.* [4] 9, 5). *V.D.* 7-32 (calc. 7-21). Formed by pouring absolute alcohol upon  $\text{SiCl}_4$  and distilling the product (Ebelmen, *A.* 57, 331). Also from alcohol and  $\text{SiF}_4$  (Knop a. Wolf, *C. C.* 1861, 899). Colourless liquid, with ethereal odour. Burns with dazzling flame. Insol. water, but slowly decomposed by it with separation of silica. Ammonia and aque-

ous alkalis dissolve it.  $\text{Ac}_2\text{O}$  at 180° gives  $(\text{EtO})_2\text{SiOAc}$  (c. 190°).

**Chloride**  $\text{ClSi}(\text{OEt})_2$ . (157°).  $\frac{2}{1}$  1-0488. *V.D.* 7-05 (calc. 6-81). Formed by heating  $\text{SiCl}_4$  (1 mol.) with  $\text{Et}_2\text{SiO}_3$  (3 mols.) at 150°; by heating  $\text{Et}_2\text{SiO}_3$  (1 mol.) with  $\text{AcCl}$  (1 mol.) at 175°; or by distilling  $\text{Et}_2\text{SiO}_3$  with  $\text{POCl}_3$ . Limpid liquid; does not fume in the air, but is quickly decomposed by moist air or water yielding  $\text{HCl}$  and silica.

**Dichloride**  $\text{Cl}_2\text{Si}(\text{OEt})_2$ . (137°). *S.G.*  $\frac{21}{1}$  1-144. *V.D.* 6-76 (calc. 6-55). From  $\text{Et}_2\text{SiO}_3$  (1 mol.) and  $\text{SiCl}_4$  (1 mol.). Formed also by heating  $\text{ClSi}(\text{OEt})_2$  (1 mol.) with  $\text{SiCl}_4$  (2 mols.) and distilling. Liquid resembling the preceding.

**Trichloride**  $\text{Cl}_3\text{Si}(\text{OEt})_2$ . (104°). *S.G.*  $\frac{2}{1}$  1-291. *V.D.* 6-38 (calc. 6-22). Formed by heating  $\text{Et}_2\text{SiO}_3$  or either of the preceding chlorides with excess of  $\text{SiCl}_4$  for a long time. Liquid.

**Octo-ethyl tetra-silicate**  $\text{Et}_8\text{Si}_4\text{O}_{12}$ . (270°–290°). *S.G.*  $\frac{2}{1}$  1-071. *V.D.* 19-54. From  $\text{Si}_2\text{O}_5\text{Cl}_2$  and absolute alcohol (T. a. H.). Liquid.  $\text{NH}_3$  converts it into  $\text{Et}_8\text{Si}_4\text{O}_{12}(\text{NH}_2)_2$ .

**ETHYL-STIBINE** v. *Organic compounds of Antimony.*

**ETHYL-STILBENE** v. **ETHYL-DI-PHENYLETHYLENE.**

**Di-ethyl-stilbene** v. **DI-ETHYL-DI-PHENYLETHYLENE.**

**ETHYL-SUCCINIC ACID**

$\text{CO}_2\text{H.C}_2\text{H}_4\text{CH}_2\text{CO}_2\text{H}$ . *Butane di-carboxylic acid*. [98°]. (243°).

**Formation**.—1. By boiling  $\alpha$ -acetyl- $\alpha$ -ethyl-succinic ether with conc. alcoholic  $\text{KOH}$  (Hugenberg, *A.* 192, 148).—2. By oxidation of  $\beta$ -acetyl-propionic acid (Thorne).—3. By distilling butane tri-carboxylic acid (derived from malonic and  $\alpha$ -bromo-butyric ethers) (Polko, *A.* 242, 121).

**Preparation**.— $\alpha$ -Acetyl- $\beta$ -ethyl-succinic ether is heated with very strong potash (2:1) at 100°. Excess of the ether removed by shaking with ether, the acids are then liberated by  $\text{H}_2\text{SO}_4$  and extracted with ether (L. T. Thorne, *C. J.* 39, 338).

**Properties**.—Prisms (from chloroform and petroleum ether); v. e. sol. water, alcohol, ether, and chloroform, insol. petroleum-ether.

**Salts**.— $\text{KHA}''$ : v. e. sol. water, insol. alcohol.— $\text{KA}''$  2aq: very hygroscopic.— $\text{CaA}''$  2aq: prisms, v. sl. sol. water.— $\text{CaHA}''$  3aq: sl. sol. water, insol. alcohol.— $\text{BaA}''$  1½aq: v. sol. water, insol. alcohol.— $\text{SrA}''$ .— $\text{CuA}''$ : blue insoluble pp.— $\text{ZnA}''$  2aq: v. e. sol. water, insol. alcohol.— $\text{Ag}_2\text{A}''$ : powder; decomposes at 110°.

**Methylether**  $\text{Me}_2\text{A}''$ . (204°). *S.G.*  $\frac{34}{1}$  1-051. Does not solidify at –19°.

**Ethylether**  $\text{Et}_2\text{A}''$ . (225°). *S.G.*  $\frac{34}{1}$  1-030.

**Anhydride**  $\text{C}_4\text{H}_4\text{O}_3$ . *S.G.*  $\frac{34}{1}$  1-165.

**Amide**: [214°]; insol. cold water.

**Di-ethyl-succinic acid**

$\text{CO}_2\text{H.C}_2\text{H}_4\text{CH}_2\text{CO}_2\text{H}$ . [190°]. *S.* 61 at 23°; 6-7 at 95°. Formed, together with an isomeric [140°], from xeronic acid  $\text{CO}_2\text{H.OEt.CO}_2\text{H}$  and  $\text{HI}$  (Otto, *A.* 239, 280). Monoclinic plates, sl. sol. water, v. sol. alcohol and ether. Converted by heating with  $\text{HCl}$  aq into the isomeric [129°].— $\text{Na}_2\text{A}''$ .— $\text{CaA}''$  2aq.— $\text{CuA}''$  aq.— $\text{ZnA}''$  2aq.

**Ethylether**  $\text{Et}_2\text{A}''$ . (234°). *S.G.*  $\frac{15}{1}$  1-991. Formed, together with the isomeric ether, by heating  $\alpha$ -bromo- (or iodo-) butyric ether with finely-divided silver at 120° to 130° (Hell, *B.* 6,

28; 18, 475, 479; 22, 67; Hjelt, *B.* 20, 3078). It is well to add some MeI.

**Anhydride** (c. 240°).

**Di-ethyl-succinic acid**

$\text{CO}_2\text{H}.\text{CH}_2\text{Et}.\text{CH}_2\text{Et}.\text{CO}_2\text{H}$ . [129°]. S. 2-4 at 23°. This acid is obtained, together with the preceding, by heating hexane tri-carboxylic acid obtained from  $\alpha$ -bromo-butyric and ethyl-malonie ethers by treatment with NaOEt (Hjelt; Hjelt a. Bischoff, *B.* 21, 2098; Zelinsky a. Bitschikni, *B.* 21, 3398). It is also formed by dissolving the anhydride of the preceding in water. Trimetric plates, v. sol. alcohol and ether. By heating quickly it is converted into the anhydride (246°). By heating for 8 hours at 220° it is converted into the isomeric acid [190°]. On heating with resorcin and  $\text{H}_2\text{SO}_4$  it gives a fluorescein.— $\text{Na}^+\text{A}^-$ .— $\text{Ca}^+\text{A}^-$  aq.— $\text{Cu}^+\text{A}^-$  aq.— $\text{Zn}^+\text{A}^-$  6aq.

**ETHYL SUCCINIMIDE** v. *Ethylimide* of Succinic acid.

**ETHYL-SUCCINURIC ACID**  $\text{C}_8\text{H}_{12}\text{N}_2\text{O}_4$ , i.e.  $\text{NHEtCO.NH.CO.C}_2\text{H}_4\text{CO.H}$ . [167°]. Formed by the action in the cold of dilute  $\text{H}_2\text{SO}_4$  on succinyl-ethyl-urea (the compound of succinimide with cyanic ether) (Menschutkin, *B.* 7, 128). Long needles (from alcohol). Decomposed at 190° into succinimide, water, and cyanic ether. Sl. sol. water and cold alcohol.— $\text{Ag}^+\text{A}^-$ : plates or needles (from hot water).

**Amide**  $\text{NHEt.CO.NH.CO.CH}_2\text{CH}_2\text{CONH}_2$ . [196°]. From succinyl-ethyl-urea and alcoholic  $\text{NH}_3$  at 100°. Needles (from alcohol). Decomposed by heating with aqueous ammonia.

**DI-ETHYL-SUCCINYL-SUCCINIC ACID** v. *Di-ethyl derivative of the dihydride of Di-ox-terephthalic acid*.

**ETHYL-SULPHAMIC ACID**  $\text{HO.SO}_2\text{NHEt}$ . Prepared by the action of  $\text{SO}_2$  on ethyl-amine (Beilstein a. Wiegand, *B.* 16, 1265). Needles. Sol. water, alcohol, and ether. Not decomposed by boiling with water.

**Salts**.— $\text{A}^+\text{Ca}^+\text{2aq}$ : large prisms, sol. water, alcohol, and ether.— $\text{A}^+\text{Ba}^+\text{1aq}$ : silvery scales. S. (90 p.c. alcohol at 18°) = 1.33, v. sol. water.— $\text{A}^+\text{Pb}^+$ : needles, sol. water and alcohol.

**Di-ethyl-sulphamic acid**  $\text{HO.SO}_2\text{NEt}_2$ . Formed by the action of  $\text{SO}_2$  on di-ethyl-amine.  $\text{A}^+\text{Ba}^+\text{2aq}$ : sol. water and alcohol, insol. ether (Beilstein a. Wiegand, *B.* 16, 1266).

**Chloride**  $\text{NEt}_2\text{SO}_2\text{Cl}$ . (208°). Formed by the action of sulphuryl chloride on di-ethyl-amine hydrochloride (Behrend, *B.* 15, 1612; *A.* 222, 184). Yellow oil, v. sol. alcohol, ether, benzene, and  $\text{CHCl}_3$ . Heavier than water.

**TETRA-ETHYL-SULPHAMIDE**  $\text{SO}_2(\text{NEt}_2)_2$ . (250°). Formed by the action of di-ethyl-amine on di-ethyl-sulphamic chloride at 60° (Behrend, *B.* 15, 1612; *A.* 222, 185). Heavy yellow oil, v. sol. alcohol, ether, benzene, and  $\text{CHCl}_3$ .

**ETHYL SULPHATES.**

**Mono-ethyl sulphate**  $\text{C}_2\text{H}_5\text{SO}_4$ , i.e.

$\text{SO}_3(\text{OH})(\text{OEt})$ . S.G. 1.316.

**Formation**.—1. From alcohol and  $\text{H}_2\text{SO}_4$  (Dabir, *Ann. Chem.* 34, 300; 43, 101; Sertürner, *Gibb. Ann.* 60, 53; 64, 6, 7; *A. Vogel, Gibb. Ann.* 63, 81; Gay-Lussac, *A. Ch.* [2] 18, 76; Dumas a. Boullay, *A. Ch.* [2] 36, 300; Serullas, *A. Ch.* [2] 39, 153; Liebig a. Wöhler, *A.* 1, 37; Liebig, *A.* 13, 27; Magnus, *A.* 6, 152; Marchand, *P.* 28, 454; 32, 345; 41, 595; Müller, *A. Ch.* [3] 19, 22).—2. From ethylene and  $\text{H}_2\text{SO}_4$  (Hennell,

*Tr.* 1826, 240; 1823, 365; Berthelot, *A. Ch.* [3] 43, 385; *C. R.* 36, 1098).—3. By heating ether with  $\text{H}_2\text{SO}_4$  (Hennell a. Magnus, *P.* 27, 386).—4. From  $\text{S}_2\text{Cl}_2$  and alcohol (Heusser, *A.* 151, 249).

**Preparation**.—A mixture of equal parts of strong sulphuric acid and strong alcohol is heated to about 100°, and, after standing in a warm place for 24 hours, diluted with water, and saturated with carbonate of barium or carbonate of lead; the solution is then filtered from the precipitated sulphate of barium or lead, and the filtrate carefully evaporated to the crystallising point. The crystals of baric or plumbic ethylsulphate are then redissolved in water, the solution is decomposed with an exactly equivalent quantity of sulphuric acid—or better, in the case of the lead-salt, with  $\text{H}_2\text{S}$ —and the filtrate is concentrated in a vacuum over oil of vitriol or chloride of calcium. Claesson (*J. pr.* [2] 19, 246) recommends taking 3 pts. of alcohol to 2 pts. of  $\text{H}_2\text{SO}_4$ ; the yield is then 77 p.c. If the mixture be kept at 100° for more than an hour a notable amount of ether is formed, and the yield of acid is diminished (Villiers, *C. R.* 91, 124).

**Properties**.—Colourless syrup, miscible with water and alcohol, insol. ether. When heated it gives off ether, leaving  $\text{H}_2\text{SO}_4$ . At a higher temperature it gives off ethylene and  $\text{SO}_2$ .

**Reactions**.—1. The aqueous solution decomposes slowly in the cold, quickly on boiling, the products being alcohol and  $\text{H}_2\text{SO}_4$ .—2. Alcohol at 130°–140° yields ether and  $\text{H}_2\text{SO}_4$ .—3.  $\text{MnO}_2$  or  $\text{K}_2\text{CrO}_7$  give aldehyde (Jacquemin a. Liës Bodard, *J.* 1857, 345).—4. On electrolysis it yields formic and acetic acids besides  $\text{H}$  and  $\text{O}$  (Renard, *A. Ch.* [5] 17, 301).—5. The  $\text{K}$  and  $\text{Ba}$  salts are decomposed by dry  $\text{HCl}$  at about 80° completely into  $\text{EtCl}$  and the corresponding sulphate (Köhler, *B.* 11, 1929).—6. Reacts with salts of organic acids forming the corresponding ethyl ethers.

**Salts**.—All the salts are v. sol. water. Their aqueous solution is decomposed by boiling, but this is prevented by the addition of a few drops of aqueous  $\text{KOH}$ . When heated with conc.  $\text{H}_2\text{SO}_4$  they give off ether, boiling dilute  $\text{H}_2\text{SO}_4$  liberates alcohol. When heated with  $\text{KOH}$  they give off alcohol. When distilled with other salts they form ethyl ethers of those salts.— $\text{NH}_4^+\text{A}^-$ : very deliquescent crystals, v. sol. water, alcohol, and ether.— $\text{KA}^+$ : S. 125 at 17°. Large monoclinic tables or laminae;  $a:b:c = 573:615:1$ ;  $\beta = 80^\circ 27'$  (Schabus, *J.* 1854, 560). Deliquescent, insol. alcohol and ether.— $\text{Na}^+\text{A}^-$ : [86°]. S. 164 at 17°. Very deliquescent hexagonal plates; efflorescent in warm air.— $\text{Li}^+\text{A}^-$ : deliquescent crystals.— $\text{Ba}^+\text{A}^-$ : 2aq: S. 109 at 17°; S.G. 1.27 2.080; monoclinic prisms;  $a:b:c = 823:979:1$ ;  $\beta = 84^\circ 39'$  (Schabus). The aqueous solution becomes turbid on boiling,  $\text{BaSO}_4$  being pptd.— $\text{Ca}^+\text{A}^-$ : 2aq: S. 100 at 8°; 125 at 17°; 157 at 30°. Monoclinic scales; permanent in the air. Sl. sol. alcohol, insol. ether.— $\text{Sr}^+\text{A}^-$ : v. sol. water.— $\text{Cd}^+\text{A}^-$ : 2aq: long prisms, v. sol. water and alcohol, insol. ether.— $\text{Co}^+\text{A}^-$ : 2aq: dark-red crystals, permanent in the air, v. sol. water and alcohol, insol. ether.— $\text{Cu}^+\text{A}^-$ : 4aq: rectangular prisms, v. sol. water and alcohol, insol. ether.— $\text{Pb}^+\text{A}^-$ : 2aq: tables, v. sol. water and alcohol, having an acid

reaction.— $\text{PbA'PbO}$ . S. 185 at  $17^\circ$ . Amorphous, sol. water and alcohol.— $\text{MgA'}$ , 4aq: crystals, v. sol. water, insol. alcohol and ether.— $\text{MnA'}$ , 4aq: roseate tables, v. sol. water and alcohol, insol. ether.— $\text{NiA'}$ , 2aq: very soluble green crystals.— $\text{ZnA'}$ , 2aq: large tables, v. sol. water and alcohol, insol. ether.— $\text{SmaA'}$ , 9aq. S.G. 1.880. Large crystals, sol. water (Clève, *Bl.* [2] 43, 171).— $\text{DiA'}$ , 9aq. S.G. 1.868 (C.).— $\text{AgA'}$  aq: scales, sol. water and alcohol.

*Chloride*  $\text{EtSO}_4\text{Cl}$ . *Sulphuric ethoxy-chloride*. ( $153^\circ$  cor.).

*Formation*.—1. From alcohol and  $\text{ClSO}_3\text{H}$ , along with ethyl-sulphuric acid.—2. By dropping  $\text{SO}_2\text{Cl}_2$  into alcohol.—3. From  $\text{EtCl}$  and  $\text{SO}_2$  (B. Williamson, *C. J.* 2, 529; 5, 576; Kuhlmann, *A.* 33, 108).—4. From  $\text{KETS}$ , and  $\text{PCl}_5$ .—5. From  $\text{ClCO}_2\text{Et}$  and fuming  $\text{H}_2\text{SO}_4$  (Wilm, *B.* 6, 505).

*Preparation*.—Ethylene is passed into  $\text{ClSO}_3\text{H}$ , and the product distilled *in vacuo*. The yield is 50 p.c. (M. Müller, *B.* 6, 227).

*Properties*.—Slightly decomposed by distilling. Insol. water. When heated with water in sealed tubes it gives  $\text{Et}_2\text{O}$ ,  $\text{EtCl}$ ,  $\text{HCl}$ , and  $\text{H}_2\text{SO}_4$  (Purgold, *Z.* [2] 4, 669).

*Reactions*.—1. With alcohol it reacts chiefly thus:  $\text{EtO.SO}_2\text{Cl} + \text{EtOH} = \text{EtO.SO}_2\text{OH} + \text{EtCl}$ , but also according to the two equations

(a)  $\text{EtO.SO}_2\text{Cl} + \text{HOEt} = (\text{EtO})_2\text{SO}_2 + \text{HCl}$ ,  
(b)  $(\text{EtO})_2\text{SO}_2 + \text{HOEt} = (\text{EtO})(\text{HO})\text{SO}_2 + \text{Et}_2\text{O}$ ,  
the last equation taking place when there is an excess of alcohol.—2. With methyl alcohol the reaction is

$\text{EtO.SO}_2\text{Cl} + \text{HOMe} = \text{MeCl} + \text{EtO.SO}_2\text{OH}$ .  
3. With amyl alcohol  $\text{EtO.SO}_2\text{Cl} + \text{C}_5\text{H}_{11}\text{OH} = \text{C}_5\text{H}_{11}\text{SO}_2\text{OH} + \text{EtCl}$ . It thus appears that the chloride of the smaller alcohol radiate is formed (Clausson, *J. pr.* [2] 19, 248).

*Di-ethyl sulphate*  $\text{C}_2\text{H}_5\text{SO}_4$ , i.e.  $\text{SO}_2(\text{OEt})_2$ . Mol. w. 154. [ $\rho$ .  $-24^\circ$ ]. ( $118^\circ$ ) at 40 mm. S.G.  $1.1837$ . Occurs in 'heavy oil of wine,' an oily mixture sometimes obtained in the preparation of ether (Marchand, *J. pr.* 15, 1; Serullas, *A. Ch.* [2] 50, 152).

*Formation*.—1. By passing vapour of  $\text{SO}_2$  into a flask containing ether surrounded by a freezing mixture. The product is washed with lime-water and rectified (Wetherill, *A.* 66, 117).—2. From dry alcohol and  $\text{SO}_2$ .—3. From  $\text{Ag}_2\text{SO}_4$  and  $\text{EtI}$  (Stempnewsky, *J. R.* 1882, 95).—4. From  $\text{ClSO}_3\text{Et}$  and alcohol (Clausson, *J. pr.* [2] 19, 257).

*Preparation*.—Absolute alcohol (200 g.) mixed with conc.  $\text{H}_2\text{SO}_4$  (450 g.) is distilled very slowly until the mixture begins to froth. The distillate separates into two layers, the lower being pure  $\text{Et}_2\text{SO}_4$  (28 g.) (Villiers, *C. R.* 90, 1291).

*Properties*.—Oil, smelling of peppermint. Solidifies at about  $-25^\circ$ . It forms double compounds with sulpha-acetates, sulpha-benzoates, and iethionates, but not with acetates, benzoates, or methane sulphonates (Geuther, *A.* 218, 288).

*Reactions*.—1. Warm baryta-water converts it into  $\text{Ba}(\text{SO}_4)_2$ .—2. When heated with water it gives alcohol;  $\text{H}_2\text{SO}_4$ , and  $\text{EtHSO}_4$ .—3. When heated with alcohol it forms ether and  $\text{EtHSO}_4$ .—4.  $\text{SO}_2$  gives ethionie ether and methionie ether (B. Hübner, *A.* 228, 208).—5.  $\text{KHS}$  gives mercaptan and  $\text{K}_2\text{SO}_4$ .—6.  $\text{NH}_3$  gives  $\text{NEt}_2\text{SO}_4$  and  $\text{NEtHSO}_4$ .

*Reference*.—DI-BROMO-DI-ETHYL SULPHATE.

**ETHYL SULPHIDE**  $\text{C}_2\text{H}_5\text{S}$ , i.e.  $\text{Et}_2\text{S}$ . Mol. w. 90. ( $98^\circ$  cor.). S.G.  $1.1838$ . V.D.  $3.00$  (calc. 3.12). H.F.p.  $28.550$  (*Th.*). H.F.v.  $26.230$  (*Th.*).  $R_\infty$  27.64 (Nasini, *G.* 13, 301).

*Formation*.—1. By the action of  $\text{K}_2\text{S}$  on  $\text{KETS}$ , on  $\text{EtCl}$ , or on other ethyl ethers (Döbereiner, *Schw.* J. 61, 377; Regnault, *A. Ch.* [2] 71, 387; Loir, *C. R.* 26, 195; Riche, *A. Ch.* [3] 43, 297).—2. By passing the vapour of  $\text{SO}_2\text{Cl}_2$  in a current of  $\text{CO}$  over zinc ethide, and distilling the product with water (F. Gauhe, *A.* 143, 266).—3. By distilling mercury mercaptide:  $\text{Hg}(\text{SEt})_2 = \text{HgS} + \text{Et}_2\text{S}$ .

*Preparation*.—An alcoholic solution of potash is divided into two equal parts: one part is saturated with  $\text{H}_2\text{S}$ , and then mixed with the other; the liquid is introduced into a tubulated retort; vapour of hydrochloric ether is passed through it to saturation; and heat is then gradually applied, the stream of hydrochloric ether vapour being still kept up. From the distillate, which contains alcohol and ether as well as sulphide of ethyl, the sulphide of ethyl is precipitated by water; it is then purified by washing with water, dehydrated by chloride of calcium, and rectified (Regnault).

*Properties*.—Oil, with alliaceous odour. Sol. alcohol. Burns readily with blue flame. Takes fire when poured into chlorine.  $\text{HgO}$  has no action on it, but lead acetate gives a yellow pp.

*Reactions*.—1. Nitric acid (S.G. 1.2) forms di-ethyl sulphoxide  $\text{Et}_2\text{SO}$ . Fuming  $\text{HNO}_3$  forms di-ethyl sulphone (Oefele, *A.* 127, 370).—2. Boiling aqueous  $\text{KOH}$  has no action, but on distilling over solid  $\text{KOH}$  there is formed  $\text{KHS}$  and alcohol.—3. Heated with sulphur at  $180^\circ$  it is partly converted into  $\text{Et}_2\text{S}_2$ ,  $\text{Et}_2\text{S}_3$ ,  $\text{Et}_2\text{S}_4$ , and  $\text{Et}_2\text{S}_5$  (Böttger, *A.* 223, 351).—4.  $\text{S}_2\text{Cl}_2$  acts energetically, forming  $\text{HCl}$ , carbon, and sulphur (B.).—5.  $\text{SOCl}_2$  forms similarly  $\text{HCl}$ , carbon,  $\text{S}$ , and  $\text{SO}_2$ .—6.  $\text{ClSO}_3\text{H}$  forms  $\text{HCl}$ , carbon,  $\text{S}$ ,  $\text{H}_2\text{SO}_4$ , and  $\text{H}_2\text{O}$ .—7.  $\text{SO}_2\text{Cl}_2$  forms  $\text{HCl}$ , carbon,  $\text{S}$ , and  $\text{SO}_2$ .—8. On passing through a red-hot tube it yields thiophene.—9. Chlorine forms chlorinated products by substitution (Riche, *A.* 92, 358).—10. Bromine forms crystalline  $\text{Et}_2\text{SBr}_2$ , whence  $\text{KI}$  gives oily  $\text{Et}_2\text{SI}_2$ , which is reconverted by  $\text{ZnEt}_2$  into  $\text{Et}_2\text{S}$  (Rathke, *A.* 152, 214).

*Reference*.—DI-CHLORO-DI-ETHYL SULPHIDE.

*Combinations*.— $\text{Et}_2\text{SHgCl}$ . [ $90^\circ$ ]. Formed as a crystalline pp. by shaking aqueous  $\text{HgCl}_2$  with  $\text{Et}_2\text{S}$  or its alcoholic solution. Monoclinic prisms (from ether or  $\text{MeOH}$ ) (Loir, *A.* 87, 369).— $(\text{Et}_2\text{S})_2\text{PtCl}_4$ . [ $108^\circ$ ]. Yellow needles (Loir, *A. Ch.* [3] 39, 441).— $(\text{Et}_2\text{S})_2\text{PtCl}_4$ . [ $81^\circ$ ]. Formed by shaking  $\text{Et}_2\text{S}$  (1 mol.) with potassium platinum chloride (2 mols.). Short, bright-yellow prisms. Almost insol. water, m. sol. alcohol, s. sol. ether, v. e. sol.  $\text{CHCl}_3$ . Changed by shaking with water and  $\text{Et}_2\text{S}$  into an isomeride [ $100^\circ$ ] crystallising in thin tables (Blonstrand, *J. pr.* [2] 27, 190).— $\text{Et}_2\text{SPbSO}_4$ , 7aq: large crystals; v. e. sol. water.— $\text{Et}_2\text{SHgI}_2$ . [ $119^\circ$ ] (Loir, *A.* 107, 234).— $\text{Et}_2\text{STiCl}_4$ .— $(\text{Et}_2\text{S})_2\text{TiCl}_4$  (Demarcay, *Bl.* [2] 20, 182).

*Methylo-compounds*  $\text{Et}_2\text{SMel}$ . *Methyl-di-ethyl-sulphine iodide*. Formed as a syrup when  $\text{Et}_2\text{S}$  and  $\text{MeI}$  are heated together with a little water (Krüger, *J. pr.* [2] 14, 195). Moist  $\text{AgCl}$  gives syrupy  $\text{Et}_2\text{SMelCl}$ . The hydroxide is a powerful base. The nitrate and sulphate crystallise in long deliquescent

needles. — ( $\text{Et}_2\text{SMeCl}$ ).  $\text{PtCl}_4$ :  $[214^\circ]$ ; pale-red monoclinic crystals; sl. sol. cold water, insol. alcohol and ether. Crystallises from water in cubes, octahedra, and tetrahedra. —  $\text{Et}_2\text{SMeAuCl}_4$ :  $[192^\circ]$ ; long pale-yellow needles; v. sol. alcohol, ether, and hot water. —  $\text{Et}_2\text{SMeCl}(\text{HgCl}_2)_2$ :  $[198^\circ]$ ; transparent prisms (from hot water). —  $\text{Et}_2\text{SMeCyHgI}_4$ :  $[116^\circ]$ ; formed by mixing cold solutions of  $\text{Et}_2\text{SMeI}$ ,  $\text{HI}$ , and  $\text{HgCy}_2$ .  $\text{H}_2\text{S}$  in presence of water gives black  $\text{HgS}$ ; on continuing the action of the gas it changes to red  $\text{HgS}$  (difference from  $\text{SEt}_2\text{Cl}(\text{HgCl}_2)_2$ ).

**Isomerides of the Methyl compounds.**  $\text{EtMeSEtI}$ . From  $\text{EtSMe}$  and  $\text{EtI}$  (Krüger, *J. pr.* [2] 14, 207). Very deliquescent needles. The chloride is a syrup, the nitrate and sulphate are deliquescent. — ( $\text{EtMeSEtCl}$ ).  $\text{PtCl}_4$ :  $[186^\circ]$  (K.);  $[205^\circ]$  (N. A. S.); prisms of cubic system (from water); insol. ether and alcohol (Nasini a. Scala, *G.* 18, 62). By repeated recrystallisation it is changed into its isomeride. —  $\text{EtMeSEtAuCl}_4$ :  $[178^\circ]$ ; pale-yellow crystalline powder; v. sol. hot water, alcohol, and ether. —  $\text{EtMeSEtCl}(\text{HgCl}_2)_2$ :  $[112^\circ]$ ; white crystalline pp. Crystallises from water in trimetric plates. —  $\text{EtMeSEtCyHgI}_4$ :  $[98^\circ]$ ; amber-yellow pp.; insol. water, alcohol, and ether. When strongly heated it yields  $\text{HgI}_2$ , a carbamide and a sulphide. Both  $\text{Et}_2\text{SMeI}$  and its isomeride  $\text{EtMeSEtI}$  give with  $\text{AgOBz}$  syrupy benzoates, which, when heated to  $115^\circ$ , yield methyl benzoate (Crum Brown a. Blaikie, *Pr. E.* 10, 254).

**Ethyl iodide**  $\text{Et}_2\text{SI}$ . **Tri-ethyl-sulphine iodide**. From  $\text{Et}_2\text{S}$  and  $\text{EtI}$  (Oefele, *A.* 132, 82; *C. J.* 17, 106; Łukasiewicz, *Z.* [2] 4, 643). Formed also, by the action of  $\text{HI}$  on  $\text{Et}_2\text{S}$  or  $\text{EtSH}$ ; and by treating mercaptan with  $\text{EtI}$  (Cahours, *A.* 135, 352; 136, 151). Trimetric plates; v. e. sol. water. Decomposed on distillation into  $\text{Et}_2\text{S}$  and  $\text{EtI}$ . Moist  $\text{Ag}_2\text{O}$  converts it into a deliquescent hydroxide  $\text{Et}_2\text{SOH}$ . This hydroxide is strongly alkaline; it absorbs  $\text{CO}_2$  from the air, ppts. metallic salts, expels  $\text{NH}_3$  from its salts, and turns red litmus blue. It forms the following salts: —  $\text{Et}_2\text{SCl}$ : deliquescent needles (from water) volatile with steam. — ( $\text{Et}_2\text{SCl}$ ).  $\text{PtCl}_4$ : monoclinic prisms,  $a:b:c = .675:1.1:1.07$ ;  $\beta = 55^\circ 6'$  (Dehn, *A. Suppl.* 4, 92).  $S$ : 3.3 at  $20.7^\circ$ . —  $\text{Et}_2\text{S}(\text{HgCl}_2)_2$ :  $S$ : 1.5 at  $20^\circ$ . —  $\text{SEt}_2\text{AuCl}_4$ : long golden needles; sl. sol. cold water. —  $\text{Et}_2\text{SNO}_3\text{AgNO}_3$ . — ( $\text{Et}_2\text{S}$ ).  $\text{SO}_2$ : indistinct crystalline aggregates. —  $\text{SEt}_2\text{Br}$ : needles; v. e. sol. water, sl. sol. alcohol, insol. ether (cf. Otto a. Rössing, *B.* 19, 1839). The ethyl iodide also forms the following combinations with metallic salt:  $\text{SEt}_2\text{IHgI}_4$ . —  $\text{SEt}_2\text{ITl}$  (Jørgensen, *J. pr.* [2] 6, 82). — ( $\text{SEt}_2\text{I}$ ).  $(\text{BiI}_4)_2$  (Kraut, *A.* 210, 321). —  $\text{SEt}_2\text{IBiI}_4$ . — ( $\text{SEt}_2\text{I}$ ).  $(\text{BiI}_4)_2$ , 9ag.

**Ethyl cyanide**  $\text{SEt}_2\text{Cy}$ . Formed by digesting  $\text{SEt}_2\text{I}$  with  $\text{KC}_2$  at  $100^\circ$  (Gauhe, *Z.* [2] 4, 622). Deliquescent needles. Resolved by heating with acids or alkalis into  $\text{Et}_2\text{S}$ , propionic acid, and  $\text{NH}_3$ . A crystalline compound  $\text{SEt}_2\text{CyAgCy}$  is obtained by digesting  $\text{Et}_2\text{SI}$  with alcohol and  $\text{AgCy}$  at  $90^\circ$ . It is decomposed by heat into  $\text{SEt}_2\text{Cy}$  and  $\text{AgCy}$  (Patein, *C. R.* 106, 861).

**Di-ethyl di-sulphide**  $\text{Et}_2\text{S}_2$ . Mol. w. 122. ( $163^\circ$  cor.). *S.G.*  $\psi$  9927. *V.D.* 4.27 (calc. 4.28).

**Formation.**—1. By distilling  $\text{KEtSO}_3$  with a concentrated aqueous solution of  $\text{K}_2\text{S}_2$  (Zeise,

*P.* 31, 371; *Pyr. Morin*, *P.* 48, 488; *A.* 32, 267; Löwig, *P.* 27, 550; 49, 326; Cahours, *A. Ch.* [3] 18, 268; *A.* 61, 98; Muspratt, *C. J.* 3, 19). — 2. By distilling oxalic ether with  $\text{K}_2\text{S}_2$ . — 3. By treating an aqueous solution of sodium mercaptide with iodine (Kekulé a. Linnemann, *A.* 123, 279). — 4. By treating mercaptan with conc.  $\text{H}_2\text{SO}_4$ , sulphurous acid being given off (Erlenmeyer a. Lisenko, *Z.* 1861, 660). — 5. By heating mercaptan with sulphur for six hours at  $150^\circ$  (M. Müller, *J. pr.* [2] 4, 39). — 6. By heating  $\text{NaSEt}$  (8 g.) with alcohol (10 g.) and sulphur (1.5 g.) at  $100^\circ$  (Böttger, *A.* 223, 348):  $2\text{NaSEt} + \text{S}_2 = \text{Et}_2\text{S}_2 + \text{Na}_2\text{S}_2$ . — 7. From mercaptan and  $\text{SO}_2\text{Cl}_2$  (Courant a. Richter, *B.* 18, 3178).

**Properties.**—Colourless oil; sol. alcohol and ether. It first floats upon water, but after a while it sinks, probably from absorption of water. Neutral to test papers. It has an alliaceous odour, and is poisonous. It is very inflammable, and burns with a blue flame. It is attacked by  $\text{Cl}$  and  $\text{Br}$ . With  $\text{HgO}$  it slowly forms a yellow mass. Its alcoholic solutions are ppt. by  $\text{HgCl}_2$  and by  $\text{Pb}(\text{OAc})_2$ .

**Reactions.**—1. Dilute nitric acid oxidises it to ethane thiosulphonic ether  $\text{C}_2\text{H}_5\text{SO}_2\text{SEt}$ . — 2. Cold  $\text{H}_2\text{SO}_4$  does not dissolve it; on warming it gives off  $\text{SO}_2$ . — 3. Heated in a sealed tube with  $\text{EtI}$  it gives  $\text{SEt}_2\text{I}$  and iodine (Saytzeff, *Z.* [2] 6, 109). — 4. Carbonised by  $\text{S}_2\text{Cl}_2$ ,  $\text{SOCl}_2$ ,  $\text{ClSO}_2\text{H}$ , and  $\text{SOCl}_2$ .

**Di-ethyl trisulphide**  $\text{Et}_2\text{S}_3$ . Obtained, together with  $\text{Et}_2\text{S}_2$ , by distilling  $\text{KEtSO}_3$  with  $\text{P}_2\text{S}_5$  (Cahours). Formed also by heating  $\text{Et}_2\text{S}$  with sulphur. Heavy yellow oil, volatile with steam. It cannot be distilled undecomposed. Mercury removes one-third of its sulphur. Copper turnings at  $150^\circ$  do so also. When suspended in water, and oxidised by fuming  $\text{HNO}_3$ , there is formed  $\text{H}_2\text{SO}_4$  and  $\text{EtSO}_3\text{H}$ . Moist  $\text{Ag}_2\text{O}$  gives  $\text{EtSO}_3\text{H}$  and  $\text{Ag}_2\text{S}$  (Müller).

**Di-ethyl tetrasulphide**  $\text{Et}_2\text{S}_4$ . Formed by treating mercaptan with  $\text{S}_2\text{Cl}_2$  in  $\text{CS}_2$  solution (Clacsson, *J. pr.* [2] 15, 214). Oil with disgusting smell. Split up by distillation in steam into  $\text{Et}_2\text{S}_2$  and sulphur.

**Di-ethyl pentasulphide**  $\text{Et}_2\text{S}_5$ . A semi-solid mass got by heating the preceding with sulphur at  $150^\circ$ .

### TRI-ETHYL-SULPHINE COMPOUNDS v. *supra*.

**ETHYL-SULPHINIC ACID v. ETHANE-SULPHINIC ACID.**

#### ETHYL SULPHITES.

**Mono-ethyl sulphite.** The potassium salt  $\text{KO.SO.OEt}$  is formed when di-ethyl sulphite is treated with cold aqueous  $\text{KOH}$  (Warltz, *A.* 143, 75). Scales (from alcohol); very unstable.

**Chloride**  $\text{EtO.SO.Cl}$  ( $122^\circ$ ). From  $(\text{EtO})_2\text{SO}$  and  $\text{PCl}_5$  (Michaelis a. Wagner, *B.* 7, 1073). Formed in small quantity by passing  $\text{HCl}$  into alcohol saturated with  $\text{SO}_2$  and heating the product in a sealed tube at  $100^\circ$ . Slightly fuming liquid. Readily decomposed by water into  $\text{HCl}$ , alcohol, and  $\text{SO}_2$ . Not attacked by  $\text{PCl}_5$  at  $120^\circ$ , but at  $180^\circ$  it yields  $\text{SOCl}_2$ ,  $\text{POCl}_3$ , and  $\text{EtCl}$ .

**Di-ethyl sulphite**  $\text{C}_2\text{H}_5\text{SO}_3$ , i.e.  $(\text{EtO})_2\text{SO}$ . ( $161^\circ$ ). *S.G.* 1.085. *V.D.* 4.78.

**Formation.**—1. By the action of absolute

alcohol on  $S_2Cl_2$ . The reaction perhaps takes place thus:  $S_2Cl_2 + HOEt = SOCl_2 + HSEt$ ; and  $SOCl_2 + 2HOEt = SO(OEt)_2 + 2HCl$ , but  $EtCl$ ,  $HCl$ , and sulphur are also formed (Carius, A. 106, 291; 110, 221; 111, 93; J. pr. [2] 2, 279; Ebelmen, A. Bouquet, A. Ch. [3] 17, 66; Warlitz, A. 143, 74).—2. By adding alcohol drop by drop to  $SOCl_2$  (Carius).

**Properties.**—Colourless liquid, smelling somewhat like mint. Miscible with alcohol and ether, but insol. water. Slowly decomposed by water. Aqueous alkalis and  $Na_2CO_3$  quickly decompose it into alkaline sulphite and alcohol. Alcoholic  $KHO$  gives a pp. of  $EtO.SO.OK$ . Alcoholic  $NH_3$  at  $130^\circ$  gives ethylamine and  $(NH_4)_2SO_3$ . Ethylamine gives  $NH_4Et$  and  $(NH_4)_2SO_3$ .  $PCl_5$  forms  $EtO.SOCl$ , which, however, on keeping, or on distilling, rapidly splits up into  $EtCl$  and  $SO_2$  (Geuther, A. 224, 223). Chlorine attacks it strongly, and in bright sunshine forms  $C_2Cl_4$ ,  $CCl_4$ ,  $COCl_2$ , and  $SO_2Cl_2$ .  $SOCl_2$  at  $120^\circ$  gives  $SO_2$  and  $EtCl$ . Diethyl sulphite is split up at  $200^\circ$  into  $SO_2$  and ether (Prinz, A. 223, 374).

**Isomeride v. Ethyl ether of ETHANE SULPHONIC ACID.**

**ETHYL SULPHOCYANIDE**  $C_2H_5NS$  i.e.  $EtS.Cy$ . ( $146^\circ$  cor.). S.G.  $\approx 1.033$ ;  $d_4^{20} 1.002$  (Buff, Z. [2] 4, 730);  $d_4^{20} 1.071$  (Nasini a. Scala, G. 17, 66);  $d_4^{20} 1.020$ . V.D. 3.02.  $R_\infty 41.4$  (N. a. S.).

**Formation** (Cahours, A. Ch. [3] 18, 264; Löwig, P. 67, 101; Muspratt, A. 65, 253).—1. By saturating a concentrated solution of potassium sulphocyanide with  $EtCl$ ; the product is diluted with an equal bulk of water and distilled, the distillate mixed with ether, diluted with water, and the ethereal solution dried over  $CaCl_2$  and rectified.—2. From  $EtI$  and silver sulphocyanide (Meyer a. Wurster, B. 6, 965).—3. By distilling equal parts of calcium ethyl sulphate with potassium sulphocyanide, both in concentrated solution.

**Properties.**—Mobile colourless oil, having a taste of anise and a pungent odour resembling mercaptan. Insol. water, miscible with alcohol and ether. Its alcoholic solution does not ppt. solutions of metallic salts.

**Reactions.**—1. Nitric acid oxidises it to ethane sulphonic acid.—2.  $KClO_3$  and  $HCl$  attack it with great violence forming ethane sulphonic acid.—3. Chlorine forms chloride of cyanogen  $Cy_2Cl_2$  and a liquid  $C_2H_5SCl_2$  ( $135^\circ$ ) (James, J. pr. [2] 30, 316).—4. Aqueous  $KOH$  at  $100^\circ$  gives  $EtS_2$ , potassium cyanate, and  $KCy$  (Brüning, A. 104, 199).—5. Boiling alcoholic  $KOH$  gives off  $NH_3$  and  $EtS_2$ .—6. Alcoholic  $K_2S$  forms  $Et_2S$  and potassium sulphocyanide.—7. Dry ammonia appears to form a little ethylthio-urea. Aqueous ammonia (S.G. .880) forms black uncrystallisable products. Dilute aqueous  $NH_3$  forms  $NH_4Cy$ , urea, and  $EtS_2$  (Jeanjean, C. R. 55, 330; Kremer, J. pr. 73, 365).—8.  $PEt$ , at  $100^\circ$  forms  $Et_2PS$  and  $Et_2PCy$  (Hofmann, B. A. 611; A. Suppl. 1, 58).—9. Dry  $H_2S$  gives di-thio-carbamic ether  $NH_2.CS.Et$ .—10. Thio-acetic acid gives  $NHAc.CS.Et$ .—11.  $MeI$  at  $105^\circ$  gives  $MeSI$  and other products (Dehn, A. Suppl. 4, 107).—12.  $HBr$  forms a compound  $EtSCyH.Br$ , (Henry, J. 1868, 652).

**Reference.**—CHLORO-ETHYL SULPHOCYANIDE.

**DI-ETHYL-SULPHONE**  $C_2H_5SO_2$ , i.e.  $Et_2SO$ . Ethane sulphinic ether. Mol. w. 122. ( $70^\circ$ ). ( $248^\circ$ ). S. 16 at  $16^\circ$ .  $R_\infty 46.60$  (in a 4.24 p.c. aqueous solution) (Kanonnikoff).

**Formation.**—1. By oxidising di-ethylsulphide with  $HNO_3$  in sealed tubes at  $100^\circ$ .—2. By oxidising di-ethyl sulphide with a solution (1.30) of  $KMnO_4$ .—3. From sodium ethane sulphinate and  $EtBr$  (Otto, B. 13, 1278).—4. By heating its  $\alpha$ -carboxylic acid to  $200^\circ$  (Otto, B. 21, 994).—5. From lerd ethide and  $SO_2$  (Frankland a. Lawrence, C. J. 35, 245).—6. By the dry distillation of its dicarboxylic acid  $SO_2(CHMe.CO_2H)_2$  (Lovén, B. 17, 2823).

**Properties.**—Trimetric tables (from hot water or alcohol). Does not reduce  $KMnO_4$ ; is not reduced by  $Zn$  and  $H_2SO_4$  (differences from di-ethyl sulphoxide, Beckmann, J. pr. [2] 17, 452). Not attacked by  $PCl_5$ , chlorine, or  $ZnEt_2$ .  $ICl_3$  at  $150^\circ$  gives  $C_2H_5ClSO$ , and other products (Spring a. Winssinger, B. 15, 446).

**ETHYL-SULPHONO-ACETIC ACID v. Methyl-ethyl sulphone carboxylic acid.**

**DI-ETHYL-SULPHONE  $\alpha$ -CARBOXYLIC ACID**  $Et_2SO.CHMe.CO_2H$ .  $\alpha$ -Ethyl-sulphono-propionic acid. The ethyl ether is obtained by boiling the ethyl ether of  $\alpha$ -chloropropionic acid with sodium ethane sulphinate (Otto, B. 21, 994). The free acid is a yellowish oil, miscible with alcohol and water. Decomposed on heating into di-ethyl-sulphone and  $CO_2$ . The Na salt is a gum.

**Di-ethyl-sulphone  $\beta$ -carboxylic acid**  $Et_2SO.CH_2.CH_2.CO_2H$ .  $\beta$ -Ethyl-sulphono-propionic acid. [ $112^\circ$ ]. The ethyl ether is obtained by the action of  $\beta$ -iodopropionic acid on sodium ethane sulphinate in an alcoholic solution (Otto, 21, 995). The free acid forms plates, v. e. sol. alcohol and ether. At  $200^\circ$  it gives  $SO_2$  and propionic acid. The Na salt crystallises from alcohol in plates, and is v. e. sol. water.

**Di-ethyl-sulphone di-carboxylic acid**  $O_2S(C_2H_4.CO_2H)_2$ . Sulpho-di-propionic acid. [ $156^\circ$ ].

**Formation.**—1. By oxidation of thio-di-lactic acid  $S(C_2H_4.CO_2H)_2$  with  $KMnO_4$ .—2. By the action of methyl iodide and sodium ethylate upon di-methyl-sulphone di-carboxylic ether (Lovén, B. 17, 2822).

**Properties.**—Four-sided tables. V. sol. water, alcohol, and ether. On heating it loses  $CO_2$ , forming di-ethyl-sulphone.

**ETHYL-SULPHONE-ETHYLAMIDE v. Ethylamide of ETHANE SULPHONIC ACID.**

**DI-ETHYL-SULPHONE-DI-METHYL-METHANE v. DI-ETHYL-PROPYLENE DI-SULPHONE.**

**ETHYL-SULPHONO-PROPIONIC ACID v. DI-ETHYL-SULPHONE CARBOXYLIC ACID.**

**ETHYL SULPHO-UREA v. ETHYL-THIO-UREA.**

**DI-ETHYL SULPHOXIDE**  $Et_2SO$ . Ethyl oxy-sulphide. Formed by heating  $Et_2S$  with dilute nitric acid (S.G. 1.2). Thick syrup, v. sol. water. Cannot be distilled. Reduced by zinc and  $H_2SO_4$  to  $Et_2S$  (Saytzeff, A. 144, 153). Chlorine gives  $EtCl$  and chlorinated derivatives of ethane sulphonic acid. Chlorine passed into its aqueous solution forms  $HCl$ ,  $EtCl$ , and  $EtSO_3Cl$  (Spring a. Winssinger, B. 15, 447).

**Di-ethyl-di-sulphoxide v. Ethyl ether of ethane thiosulphonic acid.**

**ETHYL SULPHYDRATE v. MERCAPTAN.**

**ETHYL TARTRONIC ACID v. OXY-ETHYL-MALONIC ACID.**

**ETHYL-TAURINE v. ETHYL-AMIDO-ETHANE SULPHONIC ACID.**

**ETHYL-TELLURIDE**  $\text{Et}_2\text{Te}$ . (98°) (W.; H.); (138°) (M. a. M.). From  $\text{K}_2\text{Te}$  and  $\text{K}_2\text{SO}_4$  (Wöhler, *A.* 35, 111; 84, 69; Heeren, *C. C.* 1861, 916). Reddish-yellow liquid with disgusting odour, v. sl. sol. water. Oxidised by air.

**Chloride**  $\text{Et}_2\text{TeCl}_2$ . Prepared by treating  $\text{Et}_2\text{Te}$  with  $\text{HNO}_3$ , dissolving the resulting crystalline nitrate in water, and ppg. by  $\text{HCl}$ . Oil. **Reactions.**—1. Aqueous  $\text{NH}_3$  gives  $(\text{Et}_2\text{Te})_2\text{Cl}_2\text{O}$ , crystallising in six-sided prisms, whence  $\text{Ag}_2\text{SO}_4$  gives crystalline  $(\text{Et}_2\text{Te})_2\text{H}_2\text{SO}_4$ .—2.  $\text{Ag}_2\text{O}$  forms an unstable alkaline oxide, which is reduced by  $\text{SO}_2$  to  $\text{Et}_2\text{Te}$ .

**Ethyl-chloride**  $\text{Et}_2\text{TeCl}$ . [174°]. From  $\text{ZnEt}_2$  and  $\text{TeCl}_4$  in ether (Marquardt a. Michaelis, *B.* 21, 2042). Deliquescent. Excess of  $\text{ZnEt}_2$  at 105° forms  $\text{TeEt}_2$  and butane.

**Ethyl-iodide**  $\text{Et}_2\text{TeI}$ . [92°]. From  $\text{Et}_2\text{Te}$  and  $\text{EtI}$  at 50° (Becker, *A.* 180, 263; Cahours, *A. Ch.* [5] 10, 50). Monoclinic crystals. Gives with  $\text{Ag}_2\text{O}$  an unstable alkaline base.

**DI-ETHYL-THETINE**  $\times \text{C}_2\text{H}_5\text{SO}$ , i.e.  $\text{Et}_2\text{S}(\text{OH})\text{CH}_2\text{CO}_2\text{H}$ . Obtained by adding  $\text{Ag}_2\text{O}$  to an aqueous solution of its hydrobromide (Letts, *Tr. E.* 28, 584). Thick syrup.

**Salts.**— $\text{EtSBr}\cdot\text{CH}_2\text{CO}_2\text{H}$ . Formed by shaking  $\text{Et}_2\text{S}$  with bromo-acetic acid, and allowing to stand for a few days. Colourless prisms, sol. water and alcohol, insol. ether. It forms a lead salt  $\text{Et}_2\text{SBr}\cdot\text{CH}_2\text{CO}_2\text{PbBrPbBr}$ , which crystallises either in narrow plates or in needles, sl. sol. cold, v. sol. hot, water. Strong nitric acid oxidises di-ethyl-thetino to ethane sulphonic acid.— $\times \text{EtS}\cdot\text{SO}_2\text{CH}_2\text{CO}_2\text{H}$ : syrupy liquid.— $(\text{EtS}\cdot\text{SO}_2\text{CH}_2\text{CO}_2\text{H})_2\text{PbCl}_2$ : large dark-orange crystals.— $(\text{EtS}\cdot\text{CH}_2\text{CO}_2\text{H})_2\text{SO}_4$ : syrup.

**ETHYL THIENYL HEXYL KETONE**  
 $\text{CH}=\text{CH}$

$\text{C}_{11}\text{H}_{20}\text{SO}$  i.e.  $\parallel$   $\text{C}(\text{Et})\cdot\text{S}\cdot\text{C}(\text{O})\cdot\text{C}_6\text{H}_{13}$ . (330° cor.).

From ethyl-thiophene, heptyl chloride, and  $\text{AlCl}_3$  (Schleicher, *B.* 19, 660). Yellow oil of aromatic odour. Yields on oxidation hexoic acid and thiophene  $\alpha\alpha$ -dicarboxylic acid. By heating with  $\text{H}_2\text{SO}_4$  it gives heptioic and ethyl-thiophene sulphonic and disulphonic acids.

**Oxim.**— $\text{C}_6\text{SH}_2\text{EtC}(\text{NOH})\cdot\text{C}_6\text{H}_{13}$ . [39°]. Crystalline.

**(8)-ETHYL-THIENYL METHYL KETONE**  
 $\text{C}_6\text{SH}_2\text{EtC}(\text{O})\cdot\text{CH}_3$ . *Acetodiethylthienone*. (249° cor.). S.G. 22.096. Formed by the action of acetyl chloride upon (8)-ethyl-thiophene in presence of  $\text{AlCl}_3$  (Schleicher, *B.* 18, 3020; 19, 660). Liquid. By alkaline  $\text{KMnO}_4$  it is oxidised to thiophene di-carboxylic acid.

**Oxim**  $\text{C}_6\text{SH}_2\text{EtC}(\text{NOH})\cdot\text{CH}_3$ : [110°]; white crystals.

**Phenyl-hydrasido**. [68°]. Needles. **Nitro-derivatives**  $\text{C}_6\text{SH}_2\text{Et}(\text{NO}_2)(\text{CO}_2\text{CH}_3)$ : [71°]; white needles.

**Di-ethyl-thienyl methyl ketone**  
 $\text{C}_6\text{SH}_2\text{Et}_2\text{C}(\text{O})\cdot\text{CH}_3$ . *Acetodiethylthienone*. (250°). A mixture of di-ethyl-thiophene (1 g.),  $\text{AcCl}$  (6 g.), petroleum-ether (5 g.) is slowly dropped

into petroleum-ether (30 g.), in which  $\text{AlCl}_3$  (2 g.) is suspended. The product is treated with cold water and distilled (Muhlert, *B.* 19, 635). Oil.

**Oxim**  $\text{C}_6\text{SH}_2\text{Et}_2\text{C}(\text{NOH})\cdot\text{CH}_3$ . Oil.

**ETHYL-(8)-THIOCARBAMIC ACID**. *Ethyl ether*  $\text{NHEt}\cdot\text{CO}\cdot\text{SEt}$ . (204°-208°). From mercaptan and cyanic ether (Hofmann, *B.* 2, 118). Heavy oil. Decomposed by acids or alkalis into mercaptan,  $\text{CO}_2$ , and ethylamine.

**Benzoyl derivative?**  $\text{NBzEt}\cdot\text{CO}\cdot\text{SH}$ . [74°]. From  $\text{BzCl}$  and potassium sulphocyanide in alcoholic solution (Lössner, *J. pr.* [2] 10, 235). On pouring the product into water the acid separates as hard sulphur-yellow prisms, v. sl. sol. water, v. sol. alcohol and ether. Resolved by heat into mercaptan, benzonitrile, and  $\text{CO}_2$ . Hot aqueous  $\text{KOH}$  gives  $\text{KOBz}$ , potassium sulphide, potassium carbonate, and potassium sulphocyanide.— $\text{NBzEt}\cdot\text{CO}\cdot\text{SEt}$ : small needles (from alcohol), v. sol. water, sl. sol. alcohol and ether.— $\text{AgA}'$ : flocculent pp. turns black on heating.— $\text{EtA}'$ . From the K salt and  $\text{EtBr}$ . Heavy non-volatile oil. At 105° it forms crystals [129°].— $\text{C}_6\text{H}_5\text{A}'$ ? small prisms, sol. water and alcohol; formed from isocamyl alcohol and benzoyl sulphocyanide (Miquel, *A. Ch.* [5] 11, 330).— $\text{C}_6\text{H}_5\text{A}'$ : [93°]; minute needles (from dilute alcohol); insol. water, v. sol. alcohol and ether.

**Ethyl-(8)-thiocarbamic acid**. *Ethyl ether*  $\text{NHEt}\cdot\text{CS}\cdot\text{OEt}$ . *Ethyl-urethane*. (204°-208°). From ethyl thiocarbimide and alcohol by heating for several hours at 110° (Hofmann, *B.* 2, 117). Formed also by treating ethyl thio-carbimide with alcoholic  $\text{NaOH}$ . Oil, smelling of garlic. Split up by alkalis or dilute acids into ethylamine,  $\text{H}_2\text{S}$ , alcohol, and  $\text{CO}_2$ . Conc.  $\text{H}_2\text{SO}_4$  gives off  $\text{COS}$ .

**Ethyl-di-thio-carbamic acid**  $\text{NHEt}\cdot\text{CS}\cdot\text{SH}$ . The ethylamine salt is formed by adding  $\text{CS}_2$  slowly to an ethereal solution of ethylamine at -18° (Hofmann, *B.* 1, 25; Rudneff, *J. R.* 10, 188; *B.* 11, 987; *Bz.* 1, 998); the free acid is ppg. on adding the calculated quantity of  $\text{HCl}$  to a solution of this salt. It is crystalline. It is decomposed by excess of  $\text{HCl}$  into  $\text{CS}_2$  and ethylamine.

**Salts.**—The silver salt is a white pp. decomposed by boiling water into silver sulphide and ethyl thiocarbimide.—Ethylamine salt  $\text{NHEt}\cdot\text{CS}\cdot\text{SNH}_2\text{Et}$ . [103°]. Six-sided tables (from alcohol), v. sol. water and alcohol, m. sol. ether. On boiling the alcoholic solution di-ethyl-thio-urea is formed. Iodine attacks its alcoholic solution forming di-ethyl-thio-urea,  $\text{CS}_2$ , ethyl thiocarbimide,  $\text{NH}_2\text{Et}$ , and sulphur.

**Ethyl ether EtA'**. *Di-ethyl-zanthamide*. Prepared by digesting mercaptan with ethyl-thiocarbimide at 120° for several hours (Hofmann, *Z.* [2] 5, 268). Heavy oil. Decomposed by distillation.

**Di-ethyl-di-thio-carbamic acid**. Diethylamine salt  $\text{NEt}_2\cdot\text{CS}\cdot\text{S}\cdot\text{NH}_2\text{Et}$ . From  $\text{CS}_2$  and diethylamine (Grodzki, *B.* 14, 2754). Not decomposed at 110°. Split up by iodine into diethylamine and  $\text{C}_6\text{H}_5\cdot\text{N}_3\cdot\text{S}_2$  of  $(\text{NEt}_2\cdot\text{CS})_2\text{S}_2$  [70°] which may be crystallised from alcohol.

**ETHYL-THIO-CARBAMINE-CYAMIDE v. CARBIMIDO-ETHYL-THIO-UREA.**

**ETHYL-THIO-CARBAMINE-METHYL CY-AMIDE v. METHYL-CARBIMIDO-ETHYL-THIO-UREA.**

**ETHYL-THIOCARBIMIDE**  $C_4H_7NS$  *i.e.*  $EtN.CS$ . *Ethyl mustard oil*. Mol. w. 87. (133°). V.D. 8.08 (calc. 3.02). S.G.  $\rho$  1.019;  $\rho_{25}$  .997 (Buff, Z. [2] 4, 730);  $\rho_{20}$  .995 (Nasini a. Scala, G. 17, 66).  $R_D$  43.35.

**Formation**.—1. By heating cyanic ether with  $P_2S_5$  (Michael a. Palmer, *Am.* 6, 260).—2. By adding an aqueous solution of ethylamine to  $CSCl_2$  (Rathke, A. 167, 218).—3. By distilling di-ethyl-thio-urea with  $P_2O_5$  or dry  $HCl$  (Hofmann, B. 1, 26).—4. By distilling ethylamine ethyl-di-thio-carbamate (from  $CS_2$  and  $NH_4Et$ ) with aqueous silver nitrate, or, better,  $HgCl_2$ . An excess of  $AgNO_3$  must be avoided, or some of the  $EtNCS$  will be changed into  $EtNCO$ . It is unnecessary to use pure ethylamine, the crude product of the action of alcoholic  $NH_3$  on  $EtI$  answers just as well.—5. Formed in small quantity, together with ethyl sulphocyanide and other products, by heating mercuric sulphocyanide with  $EtI$  at 180° (Michael, *Am.* 1, 417).

**Properties**.—Pungent liquid, inflames the tongue.

**Reactions**.—1. It unites directly with ammonia and primary amines forming ethyl- and ethyl-alkyl- thio-ureas.—2. Digested for some hours at 110° with alcohol it forms ethyl-( $\beta$ )-thio-carbamic ether.—3. Mercaptan at 120° gives ethyl-di-thio-carbamic ether.—4. When chlorine is passed through a cooled mixture of equal volumes of ethyl thiocarbimide and dry ether there is formed a powder which by treatment with aqueous  $NaOH$  is converted into  $(EtNCS)_2O$  [42°]. This oxide of ethyl thiocarbimide crystallises from alcohol in splendid colourless tablets and prisms, insol. water. On treatment with ammonium sulphide sulphur separates and the filtrate deposits crystals [c. 60°] (Sell, B. 6, 322).—5. Ethyl thiocarbimide (1 mol.) warmed with aldehyde-ammonia (2 mols.) and alcohol at 100° forms silvery needles of  $C_4H_7N_2S_2O$ , [119°], v. sol. alcohol, ether, and hot water. Alkalis and dilute acids give off aldehyde,  $NH_3$ , ethylamine, &c.

**ETHYL THIOCARBONATES**. *Sulphocarbonyl ethers*.

**Mono-ethyl-( $\alpha$ )-thiocarbonate**. Salts. —  $EtO.CO.SK$ . Formed by the action of alcoholic  $KOH$  or  $KSH$  on  $CS(OEt)_2$ , or of  $KOH$  on  $EtO.CO.SSEt$  (Debus, A. 75, 130, 136, 142; 82, 253). Formed also by passing  $CO_2$  into an alcoholic solution of  $KSEt$  (Chancel, *C. R.* 32, 642). Also from  $COS$  and alcoholic  $KOH$  (Bender, A. 148, 187). Long needles or prisms; v. sol. water and alcohol, insol. ether, not deliquescent. The aqueous solution decomposes on boiling into  $Et.CO_2$ , mercaptan,  $Et.S$ , and alcohol. The dry salt decomposes at 170° into  $COS$ ,  $Et.S$ , and  $K.CO_2$ . On adding acids to its aqueous solution  $COS$  and alcohol are formed. By adding iodine to its alcoholic solution there is formed  $EtO.CO.S.S.CO.OEt$ , a heavy oil, which is decomposed by alcoholic  $KOH$  giving  $EtO.CO.SK$ , sulphur, and  $K_2S$ . When  $NH_3$  is passed into its alcoholic solution\* sulphur is deposited, while  $Et.S$  and allophanic ether remain in solution (Chancel, *C. R.* 32, 644; Debus, A. 75, 142).— $(EtO.CO.S)_2Zn$ : m. sol. water and alcohol.— $(EtO.CO.S)_2Pb$ : crystalline powder, insol. water, sl. sol. alcohol.— $EtO.CO.SAg$ : unstable sticky mass, insol. water.— $(EtO.CO.S)_2Cu_2Cu_2S$  Ob-

tained by adding cupric sulphate to a solution of the K salt until the milky pp. first formed becomes yellow. This is washed with ether. It is a yellow amorphous powder.

**Di-ethyl ( $\alpha$ )-thiocarbonate**  $EtO.CO.SSEt$ . (156°). S.G.  $\rho$  1.0285.  $R_D$  34.09 (Nasini, G. 13, 302). From the K salt and  $EtBr$  in alcohol (Salomon, *J. pr.* [2] 6, 438). Also from  $NaSEt$  and  $CICO_2Et$ . Liquid with characteristic smell. Split up by water at 160° into mercaptan,  $CO_2$ , and alcohol. Alcoholic  $NH_3$  gives mercaptan and  $EtO.CO.NH_2$ . Alcoholic  $KOH$  gives mercaptan, alcohol, and potassium carbonate.

**Amide**  $EtS.CO.NH_2$ . *Isothiocarbamic ether*. *Isothiourethane*. [102°] (P.); [108°] (F.).

**Formation**.—1. By passing gaseous  $HCl$  into an alcoholic solution of ethyl sulphocyanide (Pinner, B. 14, 1082).—2. From  $HCl$  and alcoholic potassium sulphocyanide (Blankenhorn, *J. pr.* [2] 16, 375).—3. From  $CICO_2SEt$  and  $NH_3$  (Salomon, *J. pr.* [2] 7, 256).—4. From  $NH_3.CO.SNH_2$  and  $EtBr$  (Fleischer, B. 9, 991).—5. In small quantity from  $CO(SEt)_2$  and  $NH_3$  (Salomon a. Conrad, *J. pr.* [2] 10, 32).

**Properties**.—Plates, may be sublimed; sl. sol. water, v. sol. alcohol. In a sealed tube at 150° it splits up into mercaptan and cyanuric acid. Alcoholic  $NH_3$  gives urea and mercaptan. Alcoholic  $KOH$  gives  $CO_2$ , ammonia, and mercaptan.  $P_2O_5$  gives ethyl sulphocyanide.  $HgCl_2$ ,  $CuSO_4$ , and  $AgNO_3$  give pps.

**Di-ethyl ethylene ( $\alpha$ )-di-thio-di-carbonate**  $(EtO.CO.S)_2C_2H_4$ . From  $EtO.CO.SK$  and alcoholic ethylene bromide (Welde, *J. pr.* [2] 15, 52). Thick oil with unpleasant odour. Cannot be distilled. Alcoholic  $NH_3$  gives in the cold  $C_2H_4(SH)_2$  and carbamic ether. Alcoholic  $KOH$  gives in the cold  $EtO.CO.OK$  and  $C_2H_4(SH)_2$ .

**Ethyl isobutyl ( $\alpha$ )-thiocarbonate**  $EtO.CO.SC_4H_9$ . (192°). S.G.  $\rho$  .994. From  $CICO_2Et$  and  $NaSC_4H_9$  (Mylus, B. 6, 313). Alcoholic  $NH_3$  converts it into  $HSC_4H_9$  and  $EtO.CO.NH_2$ . Alcoholic  $KOH$  or  $KSH$  forms  $C_4H_9SH$ , alcohol, and  $CO_2$ .

**Isobutyl ethyl ( $\alpha$ )-thiocarbonate**  $C_4H_9O.CO.SSEt$ . (193°). S.G.  $\rho$  .994. From  $Cl.CO.C_4H_9$  and  $NaSEt$  (M.). Liquid, smelling like mercaptan. Alcoholic  $NH_3$  gives mercaptan and  $C_4H_9O.CO.NH_2$ . Warm alcoholic  $KOH$  gives  $EtSH$ , isobutyl alcohol, and  $CO_2$ .

**Ethyl-isocamyl thiocarbonate**  $CO(OEt)(SC_6H_{13})$ . From  $Cl.CO.S.C_6H_{13}$  and  $NaOEt$ . A liquid (Schöne, *J. pr.* [2] 32, 245).

**Reactions**.—1. Alcoholic  $NH_3$  reacts according to the equation  $CO(S.C_6H_{13})(OEt) + NH_3 = HSC_6H_{13} + CO(NH_2)(OEt)$ .—2. Alcoholic  $KOH$  reacts thus:  $CO(S.C_6H_{13})(OEt) + 2KOH = HSC_6H_{13} + HOEt + K_2CO_3$ .

**Ethyl ( $\beta$ )-thio-carbonyl acid**. **Chloride**  $EtO.CSCL$ . (186°). Colourless pungent oil; formed in small quantity by the action of alcohol on  $CSCL_2$ . Converted by  $NH_3$  into the amide (Klason, B. 20, 2385).

**Amide**  $EtO.CS.NH_2$ . **Xanthogenamide**. [38°] (Salomon, *J. pr.* [2] 8, 115). Formed by the action of alcoholic  $NH_3$  on  $EtO.CS.SSEt$  (Debus, A. 75, 128), on  $EtO.CS.Cl$  (Klason), on  $EtO.CS.SMe$  (Chancel, *J.* 1851, 518), or on  $(EtO.CS)_2S$ . Monoclinic pyramids. M. sol. water, v. e. sol. alcohol and ether. Split up by dry distillation into mercaptan, cyanic acid, and

**Formation.**—1. From EtO.CS.SK and EtCl (Debus), or EtBr (Salomon, *J. pr.* [2] 6, 445).—

2. By the dry distillation of  $(\text{EtO.CS})_2\text{S}_2$  (Zeise).

**Properties.**—Pale-yellow oil, smelling like garlic; miscible with alcohol and ether. It dissolves iodine. It is but slightly attacked by potassium. It is not attacked by HCl. Its alcoholic solution gives a white pp. with  $\text{HgCl}_2$ ,  $\text{HgO}$ ,  $\text{PbO}$ , and  $\text{PbO}_2$ , do not act on it.

**Reactions.**—Alcoholic KSH gives mercaptan and  $\text{EtO.CS.SK}$ . Alcoholic KOH acts in like manner.  $\text{NH}_3$ , passed into its alcoholic solution forms  $\text{Et}_2\text{S}$ ,  $\text{H}_2\text{S}$ , and  $\text{EtO.CS.NH}_2$ . Aqueous  $\text{NH}_3$  at  $135^\circ$  forms alcohol, mercaptan, and  $\text{NH}_4\text{SCy}$ . Water at  $160^\circ$  gives mercaptan, alcohol,  $\text{CO}_2$ , and  $\text{H}_2\text{S}$  (Schmitt a. Glutz, *B.* 1, 168).

**Chloride**  $\text{EtS.CSCL}$  ( $100^\circ$  in *vacuo*). S.G. 1.1408. From mercaptan and  $\text{CSCL}_2$  (Klason, *B.* 20, 2385).

**Amide**  $\text{EtS.CS.NH}_2$ . [ $42^\circ$ ]. Formed by passing  $\text{H}_2\text{S}$  into ethyl sulphocyanide at  $100^\circ$  under extra pressure (Jeanjean, *J.* 1866, 501; Salomon a. Conrad, *J. pr.* [2] 10, 29). Trimetric crystals (from ether) with unpleasant odour. Insol. water, v. e. sol. alcohol and ether. Alcoholic  $\text{NH}_3$  or KOH gives mercaptan and sulphocyanide.  $\text{EtI}$  forms crystalline  $\text{EtS.CS.NH.EtI}$ .  $\text{HgCl}_2$ ,  $\text{AgNO}_3$ , and  $\text{CuSO}_4$  give pps.

**Acetyl derivative of the Amide**  $\text{EtS.CS.NHAc}$ . [ $123^\circ$ ]. Yellow needles; sol. alcohol, ether, and hot water. Boiled with baryta-water it gives mercaptan, barium sulphocyanide, and barium acetate. Formed by the combination of thio-acetic acid with ethyl-sulphocyanide. On dry distillation it is decomposed into these constituents (Chanlaroff, *B.* 15, 1987).

**Ethylene ethyl ( $\alpha\beta$ )-di-thiocarbonate**  $(\text{EtO.CS.S})_2\text{C}_2\text{H}_4$ . [ $42^\circ$ ]. From potassium xanthate and alcoholic ethylene bromide (Welde, *J. pr.* [2] 15, 55). Long needles or tables (from ether). Alcoholic  $\text{NH}_3$  gives  $\text{EtO.CS.NH}_2$  and  $\text{C}_2\text{H}_5(\text{SH})_2$ .

**Ethyl propyl ( $\alpha\beta$ )-di-thiocarbonate**  $\text{EtO.CS.SPr}$ . S.G. 1.050.  $R_\infty$  78.55 (Nasini a. Scala, *G.* 17, 66).

**Ethyl isobutyl ( $\alpha\beta$ )-di-thio-carbonate**  $\text{C}_4\text{H}_9\text{O.CS.SEt}$ . ( $228^\circ$ ). S.G. 1.003. From  $\text{C}_4\text{H}_9\text{O.CS.SK}$  and  $\text{EtI}$  (Mylus, *B.* 5, 975).

**Di-ethyl-( $\alpha\alpha$ )-di-thiocarbonate**  $\text{CO}(\text{SEt})_2$ . ( $197^\circ$ ). S.G. 1.084.

**Formation.**—1. By warming ethyl sulphocyanide with conc.  $\text{H}_2\text{SO}_4$  (Schmitt a. Glutz, *B.* 1, 166).—2. From  $\text{NaSEt}$  and  $\text{COCl}_2$  (Salomon, *J. pr.* [2] 7, 255).—3. From di-phenyl carbonate and  $\text{NaSEt}$  (Seifert, *J. pr.* [2] 31, 464).

**Properties.**—Oil, smelling like garlic. Alcoholic  $\text{NH}_3$  splits it up into urea and mercaptan. Alcoholic KOH gives  $\text{KETCO}$ , and mercaptan. Water at  $160^\circ$  forms  $\text{CO}_2$  and mercaptan.

**Mono-ethyl tri-thio-carbonate**  $\text{EtS.CS.SH}$ . Salt.— $\text{KA}'$ . Formed by direct union of  $\text{CS}_2$  with  $\text{KSEt}$  (Chancel, *C. R.* 32, 642). Sol. water and alcohol. Its solution gives yellow pps. with salts of Ag, Pb, and Hg; and with  $\text{CuSO}_4$  a scarlet pp. of the cuprous salt. These pps. decompose when heated, leaving metallic sulphides. The K salt decomposes at  $100^\circ$  into  $\text{P}_2\text{S}_5$  and an oil  $\text{C}_2\text{H}_5\text{S}$ ?

**Di-ethyl tri-thio-carbonate**  $\text{EtS.CS.SEt}$ . ( $240^\circ$ ).

**Formation.**—1. From  $\text{K}_2\text{CS}_3$  or  $\text{Na}_2\text{CS}_3$  and  $\text{EtI}$  or  $\text{EtCl}$  (Schweitzer, *J. pr.* 32, 254; Debus,

*A.* 75, 147; Husemann, *A.* 123, 67).—2. By acting on  $\text{EtI}$  and  $\text{CS}_2$  with sodium amalgam (Nasini a. Scala, *G.* 17, 236; cf. Löwig a. Scholz, *J. pr.* 79, 441).—3. From  $\text{CSCL}_2$  and  $\text{NaSEt}$  (Klason, *B.* 20, 2385).

**Properties.**—Heavy yellow oil, v. sol. alcohol and ether. Has a slightly alliaceous odour. Burns with blue flame. When heated slowly it partially decomposes into  $\text{Et}_2\text{S}$  and  $\text{CS}_2$ . Alcoholic KOH gives  $\text{K}_2\text{CS}_3$ , mercaptan, &c. Alcoholic  $\text{NH}_3$  at  $100^\circ$  gives mercaptan and ammonium sulphocyanide. Unites with bromine, forming  $\text{Et}_2\text{CS.Br}_2$ , which crystallises from ether in large six-sided prisms, decomposed by water with liberation of  $\text{HBr}$ , and by potash with liberation of the original ether (Behrend, *A.* 128, 333). Oxidised by  $\text{HNO}_3$  to ethane sulphonic acid.

**Ethyl-ortho-thio-carbonate**  $\text{C}(\text{SEt})_2$ . S.G. 1.01. Formed by treating  $\text{COI}$  with  $\text{NaSEt}$  (Claesson, *J. pr.* [2] 15, 212). Oil, with unpleasant odour. Gives off  $\text{Et}_2\text{S}$  when heated. Volatile with steam. Oxidised by  $\text{HNO}_3$  to ethane sulphonic acid.

**ETHYL THIOCYANATE v. ETHYL SULPHOCYANIDE.**

Obtained by the action of  $\text{FeCl}_3$  upon a dilute solution of ethyl-*p*-phenylene diamine in presence of  $\text{H}_2\text{S}$  and  $\text{HCl}$ . In its properties and reactions it closely resembles the di-methylthionine (*q. v.*) (Bernthsen a. Goske, *B.* 20, 933).

( $\alpha$ )-**ETHYL-THIOPHENE**  $\text{C}_6\text{H}_5\text{S}$  *i.e.*

$\text{CH} \text{---} \text{CH}$   $\parallel \parallel$ . ( $133^\circ$  cor.). S.G. 1.990. Formed  $\text{CET.S.CH}$

by the action of sodium upon a mixture of ( $\beta$ )-bromo-thiophene and  $\text{EtBr}$  (Schleicher, *B.* 18, 3015; 19, 671); or upon  $\text{EtI}$  or  $\text{EtBr}$  and ( $\beta$ )-iodothiophene (Meyer a. Kreis, *B.* 17, 1560; Egli, *B.* 18, 544). Colourless oil. Gives Laubeneimer's reaction. By alkaline  $\text{KMnO}_4$  it is oxidised to thienyl methyl ketone, thiophene-( $\alpha$ )-carboxylic acid [ $127^\circ$ ], and thienyl-( $\alpha$ )-glyoxylic acid. Gives a tri-bromo-derivative  $\text{C}_6\text{SEtBr}_3$ : [ $108^\circ$ ]; colourless plates.

$\text{CET} \cdot \text{CH}$  ( $\beta$ )-Ethyl-thiophene  $\parallel \parallel$ . Obtained by  $\text{CH.S.CH}$

heating ethyl-succinic acid with  $\text{P}_2\text{S}_5$  (Damsky, *B.* 19, 3284). Oil.  $\text{KMnO}_4$  gives thiophene ( $\beta$ )-carboxylic acid [ $136^\circ$ ].

Di-ethyl-thiophene  $\text{C}_6\text{SH}_2\text{Et}_2$ . ( $181^\circ$  cor.). S.G. 1.962. From iodo-ethyl-thiophene,  $\text{EtI}$ , and sodium (Muhlert, *B.* 19, 633).

**References.**—Bromo-, Chloro-, Iodo-, and Nitro-ETHYL-THIOPHENE.

( $\alpha$ )-**ETHYL-THIOPHENE CARBOXYLIC ACID**  $\text{C}_6\text{SEtEt.CO}_2\text{H}$ . *Ethyl-thiophenic acid*. [ $71^\circ$ ]. Obtained by the action of sodium amalgam upon a mixture of Iodo-( $\alpha$ )-thiophene and chloroformic ether, and saponification of the product. Glistening colourless crystals. V. sol. alcohol, ether, and hot water, sl. sol. cold water. By alkaline  $\text{KMnO}_4$  it is oxidised to thiophene di-carboxylic acid.

**Salts.**— $\text{AgA}'$ : curdy pp., sol. hot water.— $\text{CaA}' \cdot 2\text{aq}$ : colourless silky needles (Schleicher, *B.* 18, 3018).

## ETHYL-TOLUENE.

### ETHYL THIOPHOSPHATES.

**Mono-ethyl thiophosphate**  $(EtO)_2PS(OH)_2$ . *Ethyl-thiophosphoric acid*. Oil formed by the action of alcohol on  $PSCl_4$ . The K and Na salts are formed by treating  $PSCl_4$  with alcoholic KOH or NaOH. They are v. sol. water and alcohol. The salts of Ba, Sr, and Ca are crystallisable.—BaA" (Cloeze, C. R. 24, 388; Chevrier, Z. 1869, 418).

**Di-ethyl-thiophosphate**  $(EtO)_2PS(OH)_2$ . *Ethyl-thiophosphoric acid*. Formed, together with  $Et_2P_2S_2O_6$ , by the action of  $P_2S_5$  on alcohol (Carius, A. 112, 190). Viscid oil, having an acid and bitter taste. It may be boiled in aqueous or alcoholic solution without decomposition, but when heated *per se* it gives off mercaptan and leaves phosphoric acid. It forms very stable salts, those of the alkalis, alkaline earths, and of lead being v. sol. water, sol. absolute alcohol and ether. The silver salt is v. sl. sol. water, but v. sol. alcohol and ether.

**Tri-ethyl thiophosphate**  $(EtO)_3PS$ . Formed by the action of alcohol on  $PSCl_4$  or  $PSBr_4$ ; and of  $PSCl_4$  on NaOEt (Carius, A. 119, 291; Chevrier, Z. 1869, 413; Michaelis, B. 5, 4). Oil, smelling like turpentine, volatile with steam. Conc.  $H_2SO_4$  appears to form  $Et_2P_2S_2O_6$  and  $Et_4P_2S_2O_6$ .

**Di-ethyl-di-thiophosphate**  $Et_2HPO_3S_2$ . Formed, together with  $Et_2S$ , by heating  $Et_2PO_3S_2$  with mercaptan in a sealed tube (Carius). The K salt is formed by the action of alcoholic KSET on  $Et_2PO_3S_2$ . Colourless amorphous mass.

**Tri-ethyl di-thio-phosphate**  $Et_3PO_3S_2$ . Formed, as above, by treating alcohol with  $P_2S_5$ . Colourless oil, with aromatic and somewhat alliaceous odour. Volatile with steam.

**Di-ethyl-tetra-thio-phosphate**  $Et_2HPS_4$ . The K salt is formed by the action of alcoholic KSI on  $Et_2PS_4$ .  $Et_2HPS_4$  crystallises in prisms (Carius, J. 1861, 583).

**Tri-ethyl tetra-thio-phosphate**  $Et_3PS_4$ . Produced by the action of  $P_2S_5$  on mercaptan, or, better, on mercury mercaptide (Carius, A. 112, 199). Light yellow oil. KOH forms, apparently,  $KEt_2POS_3$ .

**Tetra-ethyl di-thio-pyrophosphate**  $Et_4P_2S_2O_6$ . Appears to be produced by treating  $Et_2PSO_3$  with conc.  $H_2SO_4$  (Carius, Z. 1861, 305). Liquid, m. sol. water. Alcoholic KOH gives  $Et_4KP_2S_2O_6$ .

**Tetra-ethyl tri-thio-pyrophosphate**  $Et_4P_2S_3O_6$ . From  $P_2S_5$ , Br, and alcohol (Michaelis, B. 5, 8).

**Tetra-ethyl penta-thio-pyrophosphate**  $Et_4P_2S_4O_6$ . [71°] (Carius, J. 1861, 586).

**ETHYL THIOSINAMINE** v. **ETHYL-ALANIL-THIO-UREA**.

### MONO-ETHYL THIOSULPHATE

$Et_2S_2O_4$ . *Ethyl-thiosulphuric acid*.

**Formation**.—1. By treating  $Et_2S$  with an equal volume of conc.  $H_2SO_4$  (R. H. Smith, C. J. 22, 302).—2. By heating  $Et_2Br$  (1 mol.) with  $Na_2S_2O_4$  (1 mol.) with an inverted condenser (Bunte, B. 7, 646).—3. By the action of iodine on a mixture of mercaptan and  $Na_2SO_3$  (Spring, B. 7, 1162).

**Salts**.—NaA': silky six-sided needles (from alcohol). Its aqueous solution is scarcely decomposed at 100°, but on adding a small quantity of HCl it rapidly splits up into mercaptan and  $NaHSO_3$ . The dry salt is slowly converted at 100° into dithionate and  $Et_2S$ . Its aqueous

solution gives sparingly soluble pps. with  $AgNO_3$ ,  $Pb(NO_3)_2$ , and  $HgCl_2$ ; the last pp. is quickly converted on heating into  $Et_2SHgCl$ , while sulphuric acid remains in solution.  $HNO_3$  oxidises the sodium salt to sulphuric and ethane sulphonic acids. Sodium forms mercaptan and  $Na_2SO_3$ .—BaA', 2aq: colourless rectangular tables, v. sol. water, sl. sol. alcohol. The copper salt forms small dimetric tables, v. sol. water. The silver salt crystallises in small shining laminae.

**Chloride**  $Et_2S_2O_4Cl$ . From the Na salt and  $PCl_5$ . Split up by heat, giving  $Et_2S_2$  (cf. Ramsay, B. 8, 764).

**ETHYL-THIO-URAMIDO-BENZOIC ACID**  $NH_2EtCS.NH.C_6H_4.CO.H$ . *Phenyl-ethyl-thio-urea m-carboxylic acid*. [195° uncor.]. Formed by boiling m-amido-benzoic acid with ethyl-mustard-oil in alcoholic solution (Ascham, B. 17, 430). Small transparent prisms.

**ETHYL-THIO-UREA**  $C_2H_5N_2S$  i.e.  $NH_2.CS.NH.Et$ . Mol. w. 104. [113°] (Hofmann, B. 18, 2788). From ethyl thio-carbimide by direct addition of  $NH_3$  in alcoholic solution (Hofmann, Z. 1868, 686; 1870, 157; B. 1, 26). Needles (from hot water). Sol. water and alcohol. Its solution in aqueous HCl gives a yellow pp. with  $PtCl_4$ . In aqueous or alcoholic solution it is easily desulphurised by  $PbO$  or  $HgO$ , the ultimate product being tri-ethyl-melamine  $C_3N_6(NH_2)_6$ .

**Benzoyl derivative**  $NHBz.CS.NH.Et$ . [134°]. Obtained by treating benzoyl sulphocyanide with ethylamine (Miquel, A. Ch. [5] 11, 818). Slender prisms, insol. water, m. sol. boiling alcohol. Split up by boiling with aqueous HCl, giving ethylamine and benzamide.  $HgO$  gives  $NHBz.CO.NH.Et$ .

**Di-ethyl-thio-urea**  $CS(NH_2)_2$ . Mol. w. 132. Formed by the addition of ethylamine to ethyl thiocarbimide; also, with evolution of  $H_2S$ , by heating ethylamine ethyl-thio-carbamate with alcohol at 115° (Hofmann). Crystals, sol. alcohol, m. sol. water. Its solution in aqueous HCl gives a yellow crystalline pp. with  $PtCl_4$ . By  $P_2O_5$  or dry HCl it is resolved into ethylamine and ethyl thiocarbimide. It is not decomposed in aqueous or alcoholic solution by  $PbO$ , but recently ppd.  $HgO$  converts it into  $CO(NH_2)_2$ , [107°].  $HgO$  in presence of ethylamine forms tri-ethyl-guanidine.

**Tri-ethyl-thiourea**  $NH_2EtCS.NEt_2$ . [26°]. (205° uncor.). Prepared by the action of ethyl-thiocarbimide on diethylamine (Grodzki, B. 14, 2755). Colourless crystals. Sol. alcohol and ether, nearly insol. water. Alkaline reaction. Potash-fusion gives  $NH_4Et$  and  $NH_2Et$ .  $P_2O_5$  gives ethyl thio-carbimide.

**Tetra-ethyl-thiourea**  $CS(NEt_2)_2$ . (216° uncor.). S.G. 1.23-1.24 (Grodzki, B. 14, 2757). Colourless liquid. Sol. alcohol and ether, insol. water. Strong base of alkaline reaction. Very stable. Prepared by ethylation of tri-ethyl-thiourea.

**ETHYL TITANATE**  $Et_2TiO_4$ . By the action of  $TiCl_4$  (1 mol.) on alcohol (4 mols.) there is formed  $TiCl_4(OEt)_2.EtOH$  [105°-110°] whence  $NaOEt$  gives  $Ti(OEt)_4$  (Demarçay, C. R. 80, 51).

**Trichloride**  $EtO_3TiCl_3$ . [78°]. (187° cor.). From  $TiCl_4$  and ether (Bedson, A. 180, 235).

**o-ETHYL-TOLUENE**  $C_8H_9$  i.e.  $C_6H_4(OH_2)(C_2H_5)$  [1.2]. *Methyl-ethyl-benzene*

Mol. w. 120. (158° uncor.). S.G. 12 8781. Liquid at -17°. Obtained by the action of sodium upon a mixture of *o*-bromo-toluene and ethyl bromide. By dilute HNO<sub>3</sub> it is oxidised to *o*-toluic acid, and by KMnO<sub>4</sub> to terephthalic acid (?) (Claus a. Mann, B. 18, 1121).

*m*-Ethyl-toluene C<sub>9</sub>H<sub>8</sub>MeEt [1:3]. (159°). S.G. 22 869. Formed by boiling an ethereal solution of EtBr and *m*-bromo-toluene with sodium for two days (Wroblewski, A. 192, 198). Formed also by distilling abietic acid with zinc dust (Ciamician, B. 11, 270). By oxidation with CrO<sub>3</sub> it yields isophthalic acid. H<sub>2</sub>SO<sub>4</sub> forms two sulphonic acids; the Ba salt of one of these BAa', 6aq forms large crystals, sl. sol. water; that of the other forms small prisms, v. sol. water.

*Dihydrate?* C<sub>9</sub>H<sub>14</sub>. (154°). Occurs in animal oil (Weidel a. Ciamician, B. 13, 72). Gives isophthalic acid on oxidation.

*Sulphonic acids* C<sub>9</sub>H<sub>8</sub>MeEtSO<sub>3</sub>H. — BAa', 6aq. — BAa', 8aq.

*p*-Ethyl-toluene C<sub>9</sub>H<sub>8</sub>MeEt [1:4]. (161-92-162-1°) at 756-3 mm. S.G. 11-3 8694 (Schiff); 22 864 (A.). V.D. 4-11 (calc. 4-14). S.V. 161-9 (Schiff, A. 220, 93). Formed by treating *p*-bromo-toluene with ethyl bromide and sodium (Glinzer a. Fittig, A. 136, 303; Jannasch a. Dieckmann, B. 7, 1513). Formed also from ethylidene chloride, toluene, and AlCl<sub>3</sub> (Anschütz, A. 235, 314). Converted by K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> and H<sub>2</sub>SO<sub>4</sub> into *p*-toluic and terephthalic acids.

*References.*—Bromo-, Chloro-, and Nitro-ETHYL-TOLUENE.

Di-ethyl-toluene C<sub>9</sub>H<sub>8</sub>MeEt [1:3:5]. (199°). S.G. 22 879. From acetone, methyl ethyl ketone, and H<sub>2</sub>SO<sub>4</sub> (Jacobsen, B. 7, 1434). HNO<sub>3</sub> oxidises it to uvic acid.

*Isomeride v. Amyl-benzene.*

ETHYL-*o*-TOLUIDINE C<sub>9</sub>H<sub>8</sub>N i.e. C<sub>9</sub>H<sub>7</sub>(CH<sub>3</sub>)NHEt. (214° (R. a. S.); (206° (N.)). S.G. 15-3 9534. Prepared by heating *o*-toluidine hydrobromide (or hydroiodide) with 1 mol. (+ 5 p.c. excess) of ethyl alcohol at 150° for 8 hours; the yield is 54 p.c. of the theoretical.

*Acetyl derivative* C<sub>9</sub>H<sub>7</sub>(CH<sub>3</sub>)NAcEt. (255°) (Reinhardt a. Staedel, B. 16, 29; Norton, Am. 7, 118).

*Nitrosamine* C<sub>9</sub>H<sub>8</sub>Me.NEt.NO. Oil; volatile with steam.

Ethyl-*p*-toluidine C<sub>9</sub>H<sub>8</sub>Me.NHEt [1:4]. (217°). S.G. 15-3 9391. From *p*-toluidine and EtI by heating for 2 days at 100° (Morley a. Abel, C. J. 7, 68). Oil. Its sulphate and oxalate are crystalline. —B'H<sub>2</sub>PtCl<sub>4</sub>: pale-yellow crystals, sol. water and alcohol, sl. sol. ether; decomposed at 100°.

Di-ethyl-*o*-toluidine C<sub>9</sub>H<sub>7</sub>(CH<sub>3</sub>)NEt<sub>2</sub>. (208° at 755 mm.; (210° i. V.) (R.)). Formed by heating ethyl-*o*-toluidine with excess of EtI at 100°; the yield being 70 p.c. (Norton, Am. 7, 119). Prepared by heating *o*-toluidine hydrobromide (or hydroiodide) with 2 mols. (+ 5 p.c. excess) of ethyl alcohol at 150° for 8 hours; the yield is 90 p.c. of the theoretical (Reinhardt a. Staedel, B. 16, 29). Oil. Fuming nitric acid yields C<sub>9</sub>H<sub>7</sub>Me(NO<sub>2</sub>)N(NO<sub>2</sub>)Et [72°] (Van Romburgh, R. T. C. 3, 402).

*Salt.*—B'HI aq: [78°]; prisms.

Di-ethyl-*p*-toluidine C<sub>9</sub>H<sub>7</sub>(CH<sub>3</sub>)NEt<sub>2</sub> [1:4]. (228°). S.G. 15-3 9242. Formed by heating ethyl-*p*-toluidine with EtI (Morley a. Abel). Prepared by heating *p*-toluidine hydrobromide (or hydroiodide) with 2 mols. (+ 5 p.c. excess) of ethyl alcohol at 150° for 8 hours; the yield is 95 p.c. of the theoretical (Reinhardt a. Staedel, B. 16, 29). Oil. Nitric acid (S.G. 1-5) yields C<sub>9</sub>H<sub>7</sub>Me(NO<sub>2</sub>)N(NO<sub>2</sub>)Et (Van Romburgh, R. T. C. 3, 408). Diazo-benzene chloride gives C<sub>9</sub>H<sub>7</sub>N<sub>2</sub>N<sub>2</sub>Et.C<sub>6</sub>H<sub>5</sub>Me [38°]; diazo-*m*-nitro-benzene chloride reacts with formation of [3:1] C<sub>9</sub>H<sub>7</sub>(NO<sub>2</sub>)N<sub>2</sub>NEtC<sub>6</sub>H<sub>5</sub>Me [55°]; while diazo-*p*-nitro-benzene chloride gives rise to [4:1] C<sub>9</sub>H<sub>7</sub>(NO<sub>2</sub>)N<sub>2</sub>NEtC<sub>6</sub>H<sub>5</sub>Me [114°] (Noelting a. Binder, Bl. [2] 49, 81). —B'H<sub>2</sub>PtCl<sub>4</sub>: rhombohedra (Soffing, P. B. 8, 190). —B'HCiHgCl<sub>2</sub> 3aq: triclinic crystals. —B'HB: monoclinic crystals. —B'HI: crystalline. —B'IINO<sub>3</sub>: monoclinic crystals.

*Ethyl-iodide* C<sub>9</sub>H<sub>8</sub>Me.NEt.I. Heavy oil. Decomposed by moist Ag<sub>2</sub>O it gives the strongly alkaline C<sub>9</sub>H<sub>8</sub>Me.NEt.OH, whence (C<sub>9</sub>H<sub>8</sub>MeNEt.Cl)<sub>2</sub>PtCl<sub>4</sub> which crystallises from hot water in slender needles (Morley a. Abel).

ETHYL-DI-TOLYL-AMINE v. DI-TOLYL-ETHYL-AMINE.

ETHYL-TOLYLENE-DIAMINE v. TOLYLENE-ETHYL-DIAMINE.

ETHYL-TOLYL v. TOLYL-ETHYL.

ETHYL-TROPIC ACID v. TROPIC ACID under α-OXY-α-PHENYL-PROPIONIC ACID.

ETHYL-ULTRAMARINE. Prepared by heating in sealed tubes silver ultramarine and ethyl iodide, to the solid residue a further quantity of the iodide is added and the process repeated until all the silver is removed. A grey substance, evolving ethyl sulphide when heated to 100°. With sodium chloride it forms ordinary sodium ultramarine and ethyl chloride (De Forcrand, A. Ch. [5] 17, 564; C. R. 88, 30).

DI-ETHYL-UMBELLIC ACID v. UMBELLIC ACID.

ETHYL-URAMIDO-BENZOIC ACID

C<sub>9</sub>H<sub>7</sub>N<sub>2</sub>O<sub>2</sub> i.e. NHEt.CO.NH.C<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>Et. From cyanic ether and *m*-amido-benzoic acid in alcoholic solution (Griess, J. pr. [2] 5, 454). Slender needles. V. sl. sol. boiling water, v. e. sol. boiling alcohol. Acid in reaction. —BAa', 3aq: minute needles. —AgA': laminae.

*Reference.* — AMIDO-ETHYL-URAMIDO-BENZOIC ACID.

ETHYL-UREA C<sub>9</sub>H<sub>7</sub>N<sub>2</sub>O i.e. CO(NH<sub>2</sub>)(NHEt). Mol. w. 88. [92°]. S.G. 12 1-213.

*Formation.*—1. By the union of cyanic ether with ammonia (Wurtz, C. R. 32, 414).—2. By the union of ethylamine with cyanic acid (Leuckart, J. pr. [2] 21, 10).

*Properties.*—Large deliquescent prisms (from alcohol); excessively sol. water, alcohol, chloroform, CS<sub>2</sub>, and boiling benzene. Insol. ether. At 200° it decomposes with evolution of NH<sub>3</sub> and a little NH<sub>4</sub>Et, leaving a residue containing di-ethyl cyanurate (Wurtz, Rep. Chim. Pure, 1862, 199).

*Reactions.*—1. Nitrous acid forms alcohol, nitrogen, and CO<sub>2</sub>. NaOH acts in like manner.—2. A boiling aqueous solution dissolves mercuric oxide, and on cooling deposits crystals containing 53-5 p.c. of mercury (L.).—3. Evaporation with AgNO<sub>3</sub> forms silver cyanate.—4. Aniline at 150°

forms di-phenyl-urea,  $\text{NH}_4\text{Et}$ , and  $\text{NH}_3$  (L.).—5. Alcoholic KOH at  $100^\circ$  gives potassium cyanate and ethylamine (Haller, *Bt.* [2] 45, 705).

**Salts.**— $\text{B'HNO}_3$ : rosettes of thick prisms. Melts below  $60^\circ$  and then decomposes. V. sol. cold water and alcohol.— $\text{B'Cl}$ . Got by passing HCl over the base at  $100^\circ$ . At  $160^\circ$  it gives off ethylamine.— $\text{B'H}_2\text{C}_2\text{O}_4$ : [c.  $60^\circ$ ]; rectangular plates, v. sol. water and alcohol.

**Acetyl derivative**  $\text{CONH}_2\text{EtAc}$  [c.  $120^\circ$ ]. From ethyl-urea and  $\text{ClAc}$ . Stout prisms (from ether). Readily sol. water, alcohol, and ether. Sublimes in long needles. Boiled with KOH it forms potassic carbonate and acetate,  $\text{NH}_3$ , and  $\text{NEtH}$ .

**Propionyl derivative**  $\text{CONHPr}$  [(NH.COEt).  $100^\circ$ ]. Fine needles. Sol. water, alcohol, and ether. Formed from propionamide, Br, and  $\text{NaOHaq}$  (Hofmann, *B.* 15, 754).

**s-Benzoyl derivative**  $\text{CO(NHPr)(NHBz)}$ .  $168^\circ$  (L.);  $192^\circ$  (M.). From ethyl-urea and  $\text{BzCl}$  at  $130^\circ$  (Leuckart, *J. pr.* [2] 21, 33). Also from the benzoyl derivative of ethyl-thio-urea by treatment with  $\text{ppd. HgO}$  (Miquel, *A. Ch.* [5] 11, 318). Needles (from water). V. sol. alcohol, ether, and hot water.

**u-Benzoyl derivative**  $\text{NH}_2\text{CO.NEtBz}$ . From  $\text{EtS.CO.NEtBz}$  and cold alcoholic  $\text{NH}_3$  (Lössner, *J. pr.* [2] 10, 251). Rhombohedra (from dilute alcohol). V. e. sol. absolute alcohol, m. sol. ether, v. sl. sol. water.

**s-Di-ethyl-urea**  $\text{CO(NHET)}_2$ . Mol. w. 116.  $106^\circ$  (L. a. H.);  $109^\circ$ – $112.5^\circ$  (W.). ( $263^\circ$  cor.).

**Formation.**—1. From ethylamine and cyanic ether. Hence formed also by the action of water on cyanic ether (Wurtz, *C. R.* 32, 414).—2. Formed, together with cyanic ether, by the distillation of tri-ethyl-biuret (Limpriecht a. Habich, *A.* 109, 105).

**Properties.**—Silky flexible needles (from alcohol). V. sol. water, alcohol, and ether.

**Reactions.**—1. Gives off ethylamine when boiled with *potash*.—2. Heated in sealed tubes at  $100^\circ$  with alcoholic KOH it gives potassium cyanate and diethylamine (Haller, *Bt.* [2] 45, 706).

**Salts.**— $\text{B'HNO}_3$ : very acid deliquescent prisms.

**Nitrosamine**  $\text{NHET.CO.NEt.NO}$ .  $5^\circ$ . Formed by heating di-ethyl-urea with nitrous acid (Von Zotta, *A.* 179, 102; E. Fischer, *A.* 199, 284; *B.* 9, 111). Tables; sl. sol. water. Decomposed by heat, even below  $100^\circ$ , into nitrogen, ethylene, and cyanic ether. Gives Liebermann's reaction with phenol and  $\text{H}_2\text{SO}_4$ . Reduced by zinc and acetic acid to di-ethyl-semicarbazide.

**u-Di-ethyl-urea**  $\text{CO(NH}_2\text{)(NEt)}$ .  $70^\circ$ . From diethylamine and cyanic acid (Volhard, *A.* 119, 380; A. P. N. Franchimont, *R. T. C.* 2, 122). Crystals, very sweet taste. V. sol. ether and alcohol. Sol.  $\text{HNO}_3$  with absorption of heat, but afterwards a strong reaction sets in, and heat is given out;  $\text{CO}_2$  and a little  $\text{N}_2\text{O}$  being evolved, the liquid then yielding crystals of nitro-di-methyl-amine (di-methyl-nitro-amide)  $(\text{CH}_3)_2\text{N.NO}$ ,  $57^\circ$ .

**Tri-ethyl-urea**  $\text{CO(NHET)}_3$ .  $63^\circ$  (c.  $235^\circ$ ). From cyanic ether and diethylamine; formed also by treating triethylamine with vapour of cyanic acid (Wurtz; Hofmann, *Pr.* 11, 273). Soft crystals, sol. water, alcohol, and ether. It does not appear to combine with acids. Alkalis convert it into ethylamine, diethylamine, and  $\text{CO}_2$ .

**Tetra-ethyl-urea**  $\text{CO(NEt)}_4$ .  $205^\circ$  (M.);  $210^\circ$ – $215^\circ$  (W.).

**Formation.**—1. By passing  $\text{COCl}_2$  into a solution of diethylamine in ligroin (Michler, *B.* 8, 1664).—2. From  $\text{Cl.CO.NEt}_2$  and diethylamine (Wallach, *A.* 214, 275).

**Properties.**—Oil. Dissolves in acids, but is reppd. by alkalis.

**ETHYL-URETHANE v. ETHYL THIOCARBAMIC ACID.**

**ETHYL-VINYL v. BUTINENE.**

**ETHYL-VINYL OXIDE v. VINYL ETHYL OXIDE.**

**DI-ETHYL-XANTHAMIDE v. ETHYL-DI-THIO-CARBAMIC ACID.**

**ETHYL-o-XYLENE**  $\text{C}_6\text{H}_4\text{Me}_2\text{Et}$  [1:2:4]. *Dimethyl-ethyl-benzene*.  $189^\circ$ . From camphor and  $\text{ZnCl}_2$  or iodine (Armstrong a. Miller, *C. J.* 45, 148; *B.* 16, 2258). Also from bromo-o-xylene,  $\text{EtBr}$ , and sodium (Jacobsen, *B.* 19, 2516). Gives on oxidation  $\text{C}_6\text{H}_4\text{Me}_2\text{CO}_2\text{H}$ .

**Sulphonic acid**  $\text{C}_6\text{H}_4\text{Me}_2\text{EtSO}_3\text{H}$ . Tables.— $\text{BaA'}$  4aq.

**Amide**  $\text{C}_6\text{H}_4\text{Me}_2\text{EtSO}_2\text{NH}_2$ .  $126^\circ$ . Needles or prisms (from alcohol).

**Ethyl-m-xylene**  $\text{C}_6\text{H}_4\text{Me}_2\text{Et}$  [1:3:5].  $187^\circ$ . S.G.  $\varphi$  869. From ethylidene chloride,  $\text{AlCl}_3$ , and xylene (Anschütz, *A.* 235, 323). Formed also by treating a mixture of acetone and methyl ethyl ketone with  $\text{H}_2\text{SO}_4$  (Jacobsen, *B.* 7, 1432); and by treating (1,3,5)-bromo-xylene with  $\text{EtBr}$  and sodium (Wroblewsky, *A.* 192, 217). Bromine forms a tribromo-derivative  $91^\circ$ . On oxidation it gives uvicic acid  $\text{C}_6\text{H}_4\text{Me}_2(\text{CO}_2\text{H})_2$   $290^\circ$ .

**Ethyl-m-xylene**  $\text{C}_6\text{H}_4\text{Me}_2\text{Et}$  [1:3:4].  $184^\circ$ . S.G.  $\varphi$  878. From bromo-m-xylene,  $\text{EtBr}$ , and sodium (Fittig a. Ernst, *A.* 139, 184; *Z.* [2] 1, 572). Liquid. Gives a tri-nitro-derivative  $119^\circ$ .

**Sulphonic acid**  $\text{C}_6\text{H}_4\text{Me}_2\text{EtSO}_3\text{H}$ . Crystalline mass (J.).— $\text{BaA'}$  2aq: trimetric laminae, m. sol. cold water.— $\text{NaA'}$  2aq: minute flat prisms, v. e. sol. cold water.

**Amide**  $\text{C}_6\text{H}_4\text{Me}_2\text{EtSO}_2\text{NH}_2$ .  $148^\circ$ . Needles or prisms (from alcohol).

**Ethyl-p-xylene**  $\text{C}_6\text{H}_4\text{Me}_2\text{Et}$  [1:4:3].  $185^\circ$ . From (3,1,4)-bromo-p-xylene,  $\text{EtBr}$ , and sodium (Jacobsen, *B.* 19, 2516). It gives a tri-nitro-derivative  $120^\circ$ .

**Sulphonic acid**  $\text{C}_6\text{H}_4\text{Me}_2\text{EtSO}_3\text{H}$ . Large trimetric plates (from dilute  $\text{H}_2\text{SO}_4$ ).— $\text{NaA'}$  aq: tables; m. sol. cold water.— $\text{BaA'}$ : six-sided plates, m. sol. boiling water.

**Amide**  $\text{C}_6\text{H}_4\text{Me}_2\text{EtSO}_2\text{NH}_2$ .  $117^\circ$ . Pearly plates (from very dilute alcohol); m. sol. cold alcohol.

**Reference.**—TRI-BROMO-ETHYL-XYLENE.

**ETHYL-XYLYL v. XYLYL-ETHYL.**

**ETIDINE.** A name given by Greville Williams (*Laboratory*, 109) to a base  $\text{C}_{11}\text{H}_{17}\text{N}$  obtained by distilling quinoline with KOH.

**EUCALYN**  $C_8H_{12}O_4$ .  $\eta_{sp}$ .  $[\alpha] = \text{about } 50^\circ$ . A sweet, syrupy substance produced, together with glucose, by boiling melitose  $C_{12}H_{22}O_{11}$  (the sugar of the eucalyptus) with dilute sulphuric acid, and obtained, together with alcohol, by fermenting melitose with yeast (Berthelot, *A. Ch.* [3] 46, 72). Dextro-rotatory, and non-fermentable. It becomes coloured at  $100^\circ$ , and at  $200^\circ$  it forms a black insoluble substance. Dilute  $H_2SO_4$  does not affect it. Boiling baryta-water colours it strongly. It reduces Fehling's solution.

**EUCALYPTENE**. This name was applied by Cloez (*A.* 154, 372) to a hydrocarbon  $C_{10}H_{18}$ , ?  $165^\circ$ ; S.G. 12.836; V.D. 5.3, obtained by distilling eucalyptol with  $P_2O_5$ . The same name was applied by Faust & Hofmeyer (*B.* 7, 63, 1429), and by Oppenheim & Pfaff, (*B.* 7, 625) to a terpene ( $172^\circ$ - $175^\circ$ ), V.D. 68.4, said to occur in oil of eucalyptus.

**EUCALYPTOL**  $C_{10}H_{18}O$ .  $172^\circ$  (V.);  $176^\circ$  i.v. (J.). S.G. 12.923 (J.);  $d_{20} = 0.940$ . Occurs in the oil of *Eucalyptus Globulus* and is isolated from the fraction  $170^\circ$ - $180^\circ$  by conversion into the hydrochloride (Jahns, *B.* 17, 2941). Optically inactive. Probably identical with cineol. Camphor-like smell. Colourless liquid. Dry HCl forms the compound  $(C_{10}H_{17}O)_2HCl$  (Voiry, *C. R.* 106, 1419).  $KMnO_4$  oxidises it to cineolic acid  $C_{10}H_{16}O_4$  [196°] (Wallach, *A.* 246, 265).

**EUCALYPTUS MANNA** v. MELITOSE.

**EUCALYPTUS OIL**. The essential oil of *Eucalyptus Globulus* is a pale-yellow, slightly dextrorotatory liquid. S.G. .932. At  $-50^\circ$  it solidifies, and the crystals thus formed melt at  $-10^\circ$ . On distillation the first fractions contain water, formic and acetic acids, and butyric and valeric anhydrides. At  $159^\circ$  there passes over a terpene S.G. .88;  $[\alpha]_D = +40^\circ$ , which forms a hydrochloride  $C_{10}H_{17}O.HCl$  [127°];  $[\alpha]_D = 27\frac{1}{2}^\circ$ . The fraction  $170^\circ$ - $175^\circ$  contains eucalyptol which constitutes two-thirds of the oil of eucalyptus (Voiry, *C. R.* 106, 1419; cf. Cloez, *A.* 154, 372). According to Faust & Hofmeyer (*B.* 7, 63, 1429) oil of eucalyptus contains two terpenes ( $151^\circ$ ) and ( $c. 174^\circ$ ), together with cymene and a camphor-like body  $C_{10}H_{16}O$ . Oppenheim & Pfaff found in Australian eucalyptus oil a terpene ( $173^\circ$ ) whence iodine produces cymene. Wallach found in the Australian oil (from *E. amygdalina*) cineol and a levorotatory phellandrene ( $165^\circ$ - $180^\circ$ ). S.G. 12.855 (Wallach, *A.* 246, 265).

**EUCHOIC ACID** v. Di-imide of MELLITIC ACID.

**EUCHLORINE**. This name was given by Davy to a gas obtained by the reaction between  $HClAq$  and  $KClO_4$ ; it has been proved to be a mixture of  $ClO_2$  and  $Cl$  (cf. p. 12). M. M. P. M.

**EUDIOMETEER**. A graduated glass vessel used in analysis of gases, and in titrimetric analysis (v. vol. i. pp. 237 and 248). c M. M. P. M.

**EUGENOL**  $C_{10}H_{12}O$ , *etc.*  
[1.84]  $C_6H_5(OH)(OMe).CH_2.CH:CH_2$ . Mol. w. 164. V.D. 6.4 (calc. 5.7).  $(242^\circ)$  (S.);  $(251^\circ)$  (Williams);  $(252^\circ)$  (Gladstone);  $(252^\circ \text{ cor.})$  (Church). S.G. 1.068 (W.); 1.066 (G.); 1.066 (Church, *C. J.* 28, 113); 1.079 (Wassermann); 1.063 (Wa.); 1.070 (Tiemann & Kraaz, *B.* 15, 2066).  $n_D^{20}$  1.540.  $n_D^{25}$  1.554.

**Occurrence**.—In oil of cloves; in oil of bay (*Laurus nobilis*); in the oil of cinnamon leaves;

in oil of pimento; in oil of *Canella alba*; and in oil of *Illicium religiosum* (Bonastre, *A. Ch.* [1827] 35, 274; Dumas, *A. Ch.* 53, 164; A. 9, 65; 27, 151; Etting, *A.* 9, 68; Böckmann, *A.* 27, 155; Greville Williams, *Chem. Gas.* 1858, 170; Cahours, *A. Ch.* [3] 52, 201; Stenhouse, *A.* 95, 103; Wöhler, *A.* 47, 236; Baeyer, *A.* 114, 163; Gladstone, *C. J.* 17, 6; Oeser, *A.* 131, 277; Eykman, *R. T. C.* 4, 33; Erlenmeyer, *Z.* 1866, 430; Wassermann, *A.* 179, 366).

**Formation**.—By reducing coniferin in weak alkaline solution with sodium-amalgam; coniferyl alcohol being an intermediate product (Tiemann, *B.* 9, 418; Chiozza, *C. C.* 1888, 443).

**Preparation**.—Oil of cloves, obtained by distilling cloves with water, contains eugenol and a terpene. Aqueous KOH dissolves the eugenol, and, on again distilling, only the terpene passes over. On acidifying the residue the eugenol is liberated.

**Properties**.—Colourless oil, with spicy odour. Reddens litmus. Quickly resinifies when exposed to air. V. sl. sol. water, v. sol. alcohol, ether, and HOAc. Has a burning taste. Does not reduce Fehling's solution. Reduces ammoniacal silver nitrate.  $FeCl_3$  colours its alcoholic solution blue.

**Reactions**.—1. Distillation over BaO gives an oil ( $142^\circ$ ) (Calvi, *A.* 99, 242; Church, *P. M.* [4] 9, 256).—2. Distilled with HI it forms MeI and a resinous mass having nearly the composition  $C_{10}H_{16}O_2$  (Erlenmeyer, *Z.* [2] 2, 430).—3. *Potash-fusion* gives acetic and protocatechuic acids (Hlasiwetz & Grabowski, *A.* 139, 95).—4.  $P_2O_5$  forms a resin, intermediate in composition between  $C_{10}H_{12}O_2$  and  $C_{10}H_{14}O_2$ , which on distillation yields a phenol which is coloured green by  $FeCl_3$  (Hlasiwetz & Barth, *Z.* [2] 2, 83).—5.  $PCl_5$  forms  $HCl$ ,  $MeCl$ , an oily anhydride (?)  $(C_{10}H_{11}O)_2O$ , and an amorphous yellow compound  $C_{10}H_{11}PO_4$ ; insol. ether (Oeser, *A.* 131, 277).—6. *Bromine* forms di-bromo-eugenol di-bromide (*q.v.*). Acetyl-di-bromo-eugenol crystallises from ether in hexagonal prisms  $[66^\circ]$  (Boyen, *B.* 21, 1393). The acetyl and benzoyl derivatives of di-bromo-eugenol dibromide melt at  $[91^\circ]$  and  $[113^\circ]$  respectively.—7.  $KMnO_4$  oxidises it to vanillin, the methyl derivative of protocatechuic aldehyde.—8. Vapour of *cyanic acid* passed into eugenol forms the crystalline allephanate  $C_6H_5(OMe)(C_6H_5).O.CO.NH.CO.NH_2$  (Baeyer, *A.* 114, 163).—9. *Phenyl cyanate* at  $100^\circ$  forms  $C_6H_5(C_6H_5)(OMe).O.CO.NHPh$   $[96^\circ]$  (Snape, *B.* 18, 2452; *C. J.* 47, 777).—10. *Chloro-acetic acid* acting on sodium-eugenol forms the acid  $C_6H_5(OMe)(C_6H_5).O.CH_2.CO_2H$   $[81^\circ]$ , which crystallises from hot water in long needles, sol. aqueous  $Na_2CO_3$ . Its sodium salt  $NaA'1\frac{1}{2}$  aq is v. sol. cold water (Saarbach, *J. pr.* [2] 21, 151).—11. *Acetochlorhydric acid* converts potassium eugenol into the glucoside  $C_6H_5(O.C_6H_5O_4)(OMe)C_6H_5$   $[132^\circ]$ . This crystallises in needles, sol. hot alcohol, hot benzene, and hot water (Michael, *Am.* 6, 340).

**Metallic derivatives**  $NaC_6H_5O_2$ .— $HK(C_6H_5O_2)_2$ , aq.— $Ba(C_6H_5O_2)_2$ : laminae, sl. sol. cold water.

**Acetyl derivative**  $C_6H_5(OAc)(OMe).C_6H_5$ .  $[31^\circ]$ .  $(270^\circ)$ . Prepared by boiling eugenol with  $Ac_2O$  for three hours. Crystals; v. sol. alcohol and ether, insol. water and cold dilute alkalis.

Conc.  $\text{H}_2\text{SO}_4$  dissolves it with deep-red colour.  $\text{KMnO}_4$  oxidises it to acetyl vanillic acid  $\text{C}_{10}\text{H}_8\text{O}_5$ , and its homologue  $\text{C}_{11}\text{H}_{10}\text{O}_5$  (Tiemann a. Nagai, *B.* 10, 202).

#### Carbonyl derivative

$\text{C}_8\text{H}_7(\text{OMe})(\text{C}_6\text{H}_5)_2\text{CO}$ . [93°]. From sodium eugenol and  $\text{COCl}_2$  (Löwenberg, *C. C.* 1886, 390; *C. J.* 50, 789).

#### Benzoyl derivative

$\text{C}_8\text{H}_7(\text{OBz})(\text{OMe})(\text{C}_6\text{H}_5)_2$ ; [70°]; monosymmetrical crystals; sl. sol. cold alcohol, insol. water (Tiemann a. Kraaz, *B.* 15, 2067).

#### p-Methoxy-benzoyl derivative

$\text{C}_8\text{H}_7(\text{O.CO.C}_6\text{H}_4\text{OMe})(\text{OMe})(\text{C}_6\text{H}_5)_2$ . From eugenol and anisyl chloride (Cahours, *A. Ch.* [3] 52, 189). Crystalline.

#### Methyl ether $\text{C}_{11}\text{H}_{10}\text{O}$ , i.e.

$\text{C}_8\text{H}_7(\text{OMe})_2\text{C}_3\text{H}_5$ . (245°). Obtained from  $\text{C}_8\text{H}_7(\text{ONa})(\text{OMe})\text{C}_3\text{H}_5$  and  $\text{MeI}$  (Graebe a. Borgmann, *A.* 158, 282; Matsumoto, *B.* 11, 123). Oxidised by  $\text{K}_2\text{Cr}_2\text{O}_7$  in  $\text{HOAc}$  to  $\text{C}_8\text{H}_7(\text{OMe})_2\text{CO}_2\text{H}$ .  $\text{KMnO}_4$  gives an acid  $\text{C}_8\text{H}_7\text{O}_2$ , [163°]. Bromine gives  $\text{C}_8\text{H}_7\text{Br}(\text{OMe})_2\text{CH}_2\text{CHBrCH}_2\text{Br}$  [78°], which, in alcoholic solution, is converted by zinc dust into liquid  $\text{C}_8\text{H}_7\text{Br}(\text{OMe})_2\text{C}_3\text{H}_5$ . A mercury salt  $\text{Hg}(\text{C}_8\text{H}_7\text{O}_2)_2$ , [140°] is formed as a by-product in the formation of  $\text{C}_8\text{H}_7(\text{OMe})_2(\text{C}_6\text{H}_5)\text{CO}_2\text{H}$  by treating  $\text{C}_8\text{H}_7\text{Br}(\text{OMe})_2\text{CO}_2\text{H}$  with  $\text{ClCO}_2\text{Et}$  and sodium-amalgam (Wassermann, *C. R.* 88, 1206).

#### Ethyl ether $\text{C}_{12}\text{H}_{12}\text{O}$ , i.e.

$\text{C}_8\text{H}_7(\text{OEt})_2(\text{OMe})\text{C}_3\text{H}_5$ . (254°). S.G. 2 1.026; 1.5 1.012. From eugenol (50 pts.),  $\text{KOH}$  (17 pts.), water (40 pts.), and  $\text{EtBr}$  (33 pts.) by heating at 100° with inverted condenser (Wassermann, *A.* 179, 866). Oil. Gives on oxidation  $\text{C}_8\text{H}_7(\text{OEt})_2(\text{OMe})\text{CO}_2\text{H}$ . When distilled it partly polymerises, forming crystalline laminae (from alcohol) [125°]. Bromine forms  $\text{C}_{12}\text{H}_{11}\text{Br}_2\text{O}_2$  [80°], whence zinc and alcohol remove bromine, leaving  $\text{C}_{12}\text{H}_{11}\text{BrO}_2$  [48°], a product which is not acted on by  $\text{AgOAc}$ .

#### Propyl-ether $\text{C}_{13}\text{H}_{14}\text{O}$ , i.e.

$\text{C}_8\text{H}_7(\text{OPr})_2(\text{OMe})\text{C}_3\text{H}_5$ . (264°). S.G. 1.002. From eugenol (100 pts.), propyl iodide (100 pts.), and  $\text{KOH}$  (35 pts.) dissolved in alcohol. Liquid, smelling like cloves. Hot dilute  $\text{KMnO}_4$  gives  $\text{C}_8\text{H}_7(\text{OPr})_2(\text{OMe})\text{CO}_2\text{H}$ .

#### Isopropyl-ether $\text{C}_{13}\text{H}_{14}\text{O}$ , i.e.

$\text{C}_8\text{H}_7(\text{OCH}_2\text{Pr})_2(\text{OMe})\text{C}_3\text{H}_5$ . (253°). S.G. 1.000. Oxidised by  $\text{KMnO}_4$  to  $\text{C}_8\text{H}_7(\text{OCH}_2\text{Pr})_2(\text{OMe})\text{CO}_2\text{H}$ .

#### Isoamyl ether $\text{C}_{17}\text{H}_{20}\text{O}$ , i.e.

$\text{C}_8\text{H}_7(\text{OC}_4\text{H}_9)_2(\text{OMe})\text{C}_3\text{H}_5$ . (284°). S.G. 1.076.  $\text{KMnO}_4$  at 80° forms  $\text{C}_8\text{H}_7(\text{OC}_4\text{H}_9)_2(\text{OMe})\text{CO}_2\text{H}$ .

#### Hexyl ether $\text{C}_{19}\text{H}_{24}\text{O}$ , i.e.

$\text{C}_8\text{H}_7(\text{OC}_6\text{H}_{13})_2(\text{OMe})\text{C}_3\text{H}_5$ . (c. 298°).

#### Allyl ether $\text{C}_{11}\text{H}_{12}\text{O}$ , i.e.

$\text{C}_8\text{H}_7(\text{OC}_3\text{H}_5)_2(\text{OMe})\text{C}_3\text{H}_5$ . (c. 269°). S.G. 1.018. From allyl iodide and potassium eugenol. A polymeride (234°–230°) is formed at the same time.

#### Benzyl ether $\text{C}_{15}\text{H}_{16}\text{O}$ , i.e.

$\text{C}_8\text{H}_7(\text{OC}_6\text{H}_5)_2(\text{OMe})\text{C}_3\text{H}_5$ . Partially decomposed on distillation.

#### Ethylene ether $\text{C}_{11}\text{H}_{12}\text{O}$ , i.e.

$\text{C}_8\text{H}_7(\text{O.C}_2\text{H}_4)_2(\text{OMe})\text{C}_3\text{H}_5$ . [89°]. Formed by heating eugenol, ethylene bromide, and alcoholic  $\text{KOH}$  in a sealed tube (Cahours, *C. R.* 84, 157, 1195). Micaceous plates; insol. water and cold alcohol, sol. hot alcohol and ether.  $\text{KMnO}_4$  oxidises it to

$\text{C}_8\text{H}_7(\text{O.C}_2\text{H}_4)_2(\text{OMe})\text{CO}_2\text{H}$ .

#### Trimethylene ether

$\text{C}_8\text{H}_7(\text{O.C}_3\text{H}_7)_2(\text{OMe})\text{C}_3\text{H}_5$ . [83°]. From

$\text{CH}_3\text{Br}.\text{CH}_2\text{CH}_2\text{Br}$ , potassium-eugenol, and a little alcohol at 100°. Satiny crystals (from ether) or prisms (from alcohol).  $\text{KMnO}_4$  gives  $\text{C}_8\text{H}_7(\text{O.C}_3\text{H}_7)_2(\text{OMe})\text{CO}_2\text{H}$ .

#### Propylene ether

$\text{C}_8\text{H}_7(\text{O.C}_3\text{H}_7)_2(\text{OMe})\text{C}_3\text{H}_5$ . [c. 58°].

Prepared as above, using propylene bromide  $\text{CH}_3\text{CHBrCH}_2\text{Br}$  (Cahours). Needles (from ether).

#### References. — BROMO-EUGENOL and NITRO-EUGENOL.

Iso-eugenol  $\text{C}_8\text{H}_7(\text{OH})(\text{OMe})(\text{CH}_2\text{CH}_2\text{CH}_3)$

[43:1]. (c. 260°). V.D. (H=1) 82.66 (obs.).

S.G. 1.08. Formed by splitting off  $\text{CO}_2$  from

homoterulic acid by heating to c. 250° or 300°

(Tiemann a. Kraaz, *B.* 15, 2064). Oil. Dis-

solves in  $\text{H}_2\text{SO}_4$  to a red solution.  $\text{FeCl}_3$  pro-

duces a light-green colouration, turned violet by

$\text{NH}_3$ .

#### Benzoyl derivative

$\text{C}_8\text{H}_7(\text{OBz})(\text{OMe})(\text{C}_6\text{H}_5)_2$ . (160°).

#### EUGETIC ACID $\text{C}_{11}\text{H}_{12}\text{O}_2$ , i.e.

$\text{C}_8\text{H}_7(\text{OMe})(\text{OH})(\text{C}_6\text{H}_5)(\text{CO}_2\text{H})$  [3:4:1:5]. [124°].

Formed by dissolving sodium in eugenol and

passing  $\text{CO}_2$  over the resulting sodium eugenol

(Scheuch, *A.* 125, 14). Long colourless prisms

(from hot water); sl. sol. cold water, v. sol. al-

cohol and ether. Its aqueous solution is coloured

blue by  $\text{FeCl}_3$ . The acid is resolved by heat into

$\text{CO}_2$  and eugenol.

#### Methyl derivative

$\text{C}_8\text{H}_7(\text{OMe})_2(\text{C}_6\text{H}_5)\text{CO}_2\text{H}$ . [180°]. Formed by

saponifying its ether, which is produced by treat-

ing the methyl derivative of bromo-eugenol with

$\text{ClCO}_2\text{Et}$  and sodium-amalgam (Wassermann,

*C. R.* 88, 1206). Flat yellow needles; sl. sol.

water, v. sol. alcohol and ether. Gives on ox-

idation by  $\text{KMnO}_4$  an acid [163°].

#### EULYSIN $\text{C}_{21}\text{H}_{24}\text{O}_2$ . A substance which may

be extracted along with cerisin and decacrylic

acid from cork by boiling with alcohol. It is v.

sol. alcohol, but insol. water (Siewert, *Z.* 1868,

883).

#### EULYTE $\text{C}_{11}\text{H}_{14}\text{N}_2\text{O}_2$ . [99.5° cor.]. S. -01 at

10°. Formed, together with eulyte, by treating

citraconic acid with strong nitric acid (Baup, *A.*

81, 96; Bassett, *C. J.* 25, 98). Eulyte is the

more soluble, it crystallises from chloroform in

large dimetric crystals. Heated with alcoholic

$\text{KOH}$  it forms  $\text{KNO}_3$  and a brown resin soluble

in alkalis.  $\text{TiCl}_4$  and  $\text{HCl}$  give  $\text{NH}_3$  and a volatile

base smelling like picoline.

#### EUONYMIN. A bitter resin obtained from

the oil of the spindle-tree, *Euonymus europaeus*

(Riederer, *Buch. Rep.* 14, 1; Grundner, *Buch.*

*Rep.* 97, 315). Insol. water, sol. alcohol and

ether, separating from the latter in warty crys-

tals.

The same name is given by Romm (*C. C.*

1885, 442; *C. J.* 50, 72) to a gummy which

may be extracted by dilute alc. ho (70 p.c.) from

the rinds of *Euonymus atropurpureus*. It may

be crystallised from ether.

#### EUPHORBIIUM. A resin consisting of the

concrete juice of several species of *Euphorbia*

growing in hot climates. Cold alcohol extracts,

according to Johnston (*J. pr.* 26, 145), a brown-

ish-red resin  $\text{C}_{20}\text{H}_{20}\text{O}$ , insol. alkalis, but dis-

solving with red colour in conc.  $\text{H}_2\text{SO}_4$ . Boiling

alcohol extracts from the residue another resin

$\text{C}_{20}\text{H}_{22}\text{O}$ , which separates in indistinct crystals

(H. Rose, P. 33, 88; 53, 365; Flückiger, J. 1868, 809). According to Henke (*Ar. Ph.* [3] 24, 729) euphorbium contains, besides euphorbone, two resins, one soluble in ether, the other not.

**EUPHORBONE**  $C_{20}H_{34}O$ . [63°].  $[\alpha]_D = 15.9^\circ$ . S. 01 (hot). Extracted from euphorbium by light petroleum at 70° and crystallised from alcohol-ether (Henke, *Ar. Ph.* [3] 24, 729; cf. Flückiger, Z. [2] 4, 221). Brilliant crystals, persistent in the air, tasteless, and neutral in solution. V. sol. light petroleum, chloroform, ether, alcohol, benzene, and acetone. Not affected by dilute acids, alkalis, or  $Ac_2O$ . Heating with  $P_2O_5$  gives heptane, octane, and xylene. According to Hesse (*A.* 192, 193) euphorbone is  $C_{18}H_{28}O$  [114°].  $[\alpha]_D = 18.8^\circ$  at 15° (in chloroform); or 11.7° (in ether).

**EUPITTONIC ACID**  $C_{22}H_{38}O_8$ . [about 200°]. Occurs amongst the products of oxidation of wood-tar oil (Liebermann, B. 9, 334; Gratzel, B. 11, 2085). Prepared by heating the dimethyl ether of pyrogallol with  $C_2Cl_4$  and alcoholic KOH (Hofmann, B. 11, 1455). Formed also by heating a mixture of the di-methyl ethers of pyrogallol ( $C_6H_3(OMe)_3OH$ ) and of methyl-pyrogallol ( $Me.C_6H_3(OMe)_2OH$ ) with NaOH at 210°, hydrogen being liberated (Hofmann, B. 12, 1377). Long fine orange needles. Difficultly soluble in boiling alcohol, easily in acetic acid. Alkaline solutions are deep blue. By an excess of alkali blue salts are precipitated. HCl at 100° gives pyrogallol and MeCl. Alcoholic  $NH_3$  at 170° gives crystalline  $C_{22}H_{38}N_2O_8$ . Water (2 pts.) at 265° gives  $C_6H_3(OMe)_3OH$  and a crystalline body.

Salts. —  $Na_2C_{22}H_{38}O_8$  aq: prisms. —  $BaC_{22}H_{38}O_8$  aq: needles.

**Di-acetyl derivative**  $C_{22}H_{38}O_8(OAc)_2$ : [265°]; yellow needles.

**Di-benzoyl derivative**  $C_{22}H_{38}O_8(Obz)_2$ : [232°]; small yellow needles. Insol. alcohol, sol. chloroform.

**Methyl ether**  $C_{22}H_{40}O_8(OMe)_2$ : [242°]; yellow needles.

**Ethyl ether**  $C_{22}H_{42}O_8(OEt)_2$ : [242°]; yellow needles.

**Periodide**  $C_{22}H_{38}O_8I_4$ : brown glistening prisms (Hofmann, B. 12, 2216).

**EURHODINES** is the name given by Witt to a class of red colouring matters which have the constitution of amido-quinoxalines. These bodies are produced: (1) By the action of a tri-amine (amido-o-diamine) upon a quinone or di-ketone. (2) By heating an o-amido-azo-compound with (α)-naphthylamine hydrochloride. Quite recently (B. 21, 2418) Witt has proposed to extend the meaning of the term eurhodine so as to include all poly-amido-derivatives of azines.

The eurhodine from o-amido-azo-toluene and (α)-naphthylamine has the constitution:

(amido-naphthylene-toluquinazolin or amido-tolu-naphthiazine). This compound crystallises from aniline or phenol in dark orange needles, almost insol. alcohol and ether. It may be sublimed. Its hydrochloride  $C_{22}H_{27}N_3HCl$  aq

forms garnet-coloured needles. Conc.  $H_2SO_4$  dissolves it with intense red colour turned green and then scarlet on gradual dilution. It dyes silk scarlet in an acid bath. The tartrate dyes cotton mordanted with Turkey-red oil a colour similar to Turkey-red (Witt, C. J. 49, 391; B. 18, 1119; 19, 914); ethyl nitrite decomposes the eurhodine in alcoholic solution, one product being lemon-yellow needles  $C_{22}H_{27}N_3O$  40.  $C_{22}H_{27}N_3O$  [175°].

The eurhodine from (β)-naphthylamine is formed on adding quinone dichlorimide to (β)-naphthylamine dissolved in alcohol the solution becoming red and, on adding water, a eurhodine  $C_{22}H_{27}N_3O$  (or, more probably,  $C_{22}H_{27}(NH_2).N_3O$ ) separates. This crystallises from benzene in dark yellow needles, m. sol. alcohol and benzene, v. sol. aniline. Its alcoholic solution is converted by nitrous acid into naphthophenazine (Nietzki a. Otto, B. 21, 1598).

A di-methylated eurhodine

$C_{20}H_{27}N_3O$  [205°] is formed by heating nitroso-di-methyl-aniline hydrochloride (3 mols.) with a solution of (β)-naphthylamine (2 mols.) in HOAc (Witt, B. 21, 719).

**EUXANTHIC ACID**  $C_{18}H_{16}O_{10}$ . *Purreeic acid*. The magnesium salt constitutes the essential part of Purree or Indian yellow, said to be obtained by evaporating the urine of cows fed on mangoes (Stenhouse, A. 51, 423; Erdmann, J. pr. 33, 190; 37, 385; Baeyer, A. 155, 257). Purree is boiled with water and the residue extracted with dilute HCl; on cooling the euxanthic acid separates in stellate groups of needles. Euxanthic acid is also excreted in small quantity by a rabbit after taking euxanthone (Kostanecki, B. 19, 2919).

**Properties.**—Pale-yellow needles, containing aq when crystallised from alcohol, but 3aq when ppd. by HCl from its ammoniacal solution. It has a sweet taste and a bitter aftertaste. It is sl. sol. cold water, v. sol. boiling alcohol, m. sol. ether. Alkalis colour its solution deep-yellow. When cautiously heated at 170° it gives off water and  $CO_2$  leaving a yellow sublimate of euxanthone. Alcohol and HCl also give euxanthone.  $HNO_3$  gives tri-nitro-euxanthone and tri-nitro-resorcin. By heating with dilute  $H_2SO_4$  (2 p.c.) at 140° it is split up into euxanthone and glyconic acid (Spiegel, B. 15, 1965).

**Salts.**—The euxanthates of the alkalis are v. e. sol. water, but are ppd. by excess of alkaline carbonate. The euxanthates of Ba, Ca, and Mg are sl. sol. cold, v. sol. hot, water. The basic Mg salt which occurs in purree is insol. water.— $NH_4HA$  aq: light-yellow needles.— $KHA$  aq.— $MgA$  9aq?: occurs in purree.— $PbHA$  aq.— $PbA$ . Di-bromo-euxanthic acid  $C_{18}H_{14}Br_2O_{10}$ . Minute golden-yellow needles (containing aq).

Di-chloro-euxanthic acid  $C_{18}H_{14}Cl_2O_{10}$ . Formed by passing Cl into water in which euxanthic acid is suspended. Golden scales; insol. water, v. sol. boiling alcohol. Its salts are mostly gelatinous.

**Nitro-euxanthic acid**  $C_{18}H_{13}(NO_2)_3O_{10}$ . From the acid and cold  $HNO_3$  (S.G. 1.31). Straw-coloured laminae (from alcohol).

**EUXANTHONE**  $C_{18}H_{16}O_8$  i.e.

or more probably

$C_6H_5(OH)-O$   
 $|$   
 $C_6H_5(OH)-CO$

product of the decomposition of euxanthic acid (Stenhouse, A. 51, 426; Erdmann, A. 52, 365; 60, 239; Schmidt, A. 93, 88; Graebe, B. 16, 864). It is produced by heating the acid or its Ba or Pb salt; by treating the dry acid with conc.  $H_2SO_4$ ; or by treating its alcoholic solution with  $HCl$ . Pale-yellow needles or laminae (from alcohol); v. sl. sol. water, v. sol. ether, sl. sol. alcohol (Kütz, Z. B. 23, 475). It may be sublimed. It is neutral in reaction, dissolves in alkalis, but not in dilute acids. The alcoholic solution is ppd. by lead subacetate, but not by lead acetate, baryta, or lime.  $FeCl_3$  gives a green colour. Does not react with hydroxylamine or with phenyl-hydrazine (Spiegler, B. 17, 808).

**Reactions.**—1. Nitric acid forms tri-nitro-euxanthone and tri-nitro-resorcin. —2. Passing over heated zinc-dust forms  $CH_2 \begin{smallmatrix} C_6H_5 \\ C_6H_5 \end{smallmatrix} O$  and

other products.—3. Potash-fusion gives hydroquinone and euxanthonic acid (Baeyer, Z. [2] 5, 569).—4. Sodium-amalgam gives a colourless compound which turns violet-black in the air (Wichelhaus a. Salzmann, B. 10, 1398).

**Salts.**—A<sup>+</sup>Mg: insol. water, nearly insol. alcohol.

**Methylether** A<sup>+</sup>Me: [130°]; yellow needles or prisms, sol. alcohol and ether (Graebe a. Ebrard, B. 15, 1675).

**Ethylether** A<sup>+</sup>Et: [126°]; long colourless or yellow prisms, sol. alcohol and ether.

**Acetyl derivative**  $C_{12}H_{10}Ac_2O_2$ : [185°]; yellowish prisms (from benzene); sol. alcohol, sl. sol. ether.

**Benzoyl derivative**: [214°]; yellow crystals, sol. aniline, insol. alcohol, ether, benzene, &c.

**Constitution.**—Euxanthone is clearly a di-oxy-derivative of the so-called di-phenylene ketone oxide, but as this substance does not react with hydroxylamine, Spiegler suggests that

it should be represented by the formula  $\begin{smallmatrix} C_6H_5O \\ | \\ C_6H_5CO \end{smallmatrix}$

rather than  $CO \begin{smallmatrix} C_6H_5 \\ C_6H_5 \end{smallmatrix} O$ .

**Di-chloro-euxanthone**  $C_{12}H_8Cl_2O_2$ . From di-chloro-euxanthic acid by dissolving in conc.  $H_2SO_4$  and ppg. by water (Erdmann, J. pr. 37, 397). Yellow powder.

**Tri-nitro-euxanthone**  $C_{12}H_5(NO_3)_3O_2$ . From euxanthone and  $HNO_3$ . Minute yellow needles. Further treatment with  $HNO_3$  gives tri-nitro-resorcin.  $NH_3$  forms reddish-black grains of  $C_{12}H_5(NH_4)(NO_3)_3O_2$ .

**Iso-euxanthone**  $\begin{smallmatrix} C_6H_5(OH)CO \\ | \\ C_6H_5(OH)O \end{smallmatrix}$ . **Lactone of tri-oxy-diphenic acid.** [243°]. Obtained by heating di-oxy-benzoic acid (*β*-resorcylic acid) with acetic anhydride; the yield is about 4 p.c. (Bistrzycki a. Kostanecki, B. 18, 1936). Small needles. V. sol. alcohol, ether, and aqueous alkalis forming yellow solutions, insol. water. Sublimes in long yellow needles.  $FeCl_3$  gives a greyish-green colour. The alcoholic solution gives a yellow pp. with  $MgSO_4$ . Treated with

sodium-amalgam and water it dissolves with a blood-red colour.

**EUXANTHONIC ACID**  $C_{12}H_8O_3$ , i.e.  $\begin{smallmatrix} [2] \\ [1] \end{smallmatrix} C_6H_5(OH)_2.CO.C_6H_5(OH)_2 \begin{smallmatrix} [1] \\ [2] \end{smallmatrix}$ . **Tetra-oxy-benzophenone** (?). Formed from euxanthone by potash-fusion (Baeyer, A. 155, 259). Yellow needles (from water). Forms a reddish-yellow pp.  $C_{12}H_8Pb_2O_3$  with basic lead acetate. Its solution in potash rapidly oxidises in the air, becoming dark.  $FeCl_3$  colours it red. Resolved by heat into water and euxanthone, which sublimes. Boiling aqueous  $NH_3$  also forms euxanthone. Potash-fusion converts it into hydroquinone (Graebe a. Feer, B. 19, 2607).

**EVERNIC ACID**  $C_{12}H_8O_4$ . [164°]. Obtained, together with uspic acid, by macerating the lichen *Evernia prunastri* with milk of lime and ppg. the filtrate with  $HCl$ ; it is extracted from the dried ppt. with boiling alcohol and ppd. by water (Stenhouse, A. 68, 83; Pr. 18, 222). Groups of 'small needles (from alcohol). Insol. cold water, v. sol. cold alcohol and ether. It does not decompose solutions of  $NaHCO_3$  in the cold; its Ca salt is decomposed by  $CO_2$ . Decomposed by boiling with water or baryta-water into  $CO_2$ , orcin, and everninic acid.

**Salts.**— $BaA_2$ , aq.; small prisms, sl. sol. cold water, v. sol. dilute alcohol.— $KA'$ : silky crystals, sl. sol. cold water, v. sol. dilute alcohol and aqueous KOH.

**Tetra-bromo-evernic acid**  $C_{12}H_4Br_4O_4$ . [161°]. From dry evernic acid and dry Br. Colourless prisms (from alcohol); insol. water and  $CS_2$ , sl. sol. hot benzene, v. sol. ether.

**EVERNIIN**  $C_{12}H_8O_4$  (Stüde, A. 131, 241). A substance extracted from *Evernia prunastri* and related to the sugars. The plant is macerated with cold dilute soda-ley till the liquid acquires a dark-green colour; the filtrate is mixed with alcohol; and the brown flocks thereby precipitated are redissolved in water and purified by repeated precipitation and boiling with animal charcoal.

Everniin is an amorphous, yellowish, tasteless powder, which swells up in cold water and dissolves easily in hot water. Its aqueous solution gives with lead acetate and ammonia a pp. soluble in acetic acid. It is ppd. by a large excess of glacial acetic acid. It prevents the ppn. of lead by  $H_2S$  or sulphuric acid, a property likewise possessed by glycogen, inulin, lichenin, and gum. Everniin is not coloured by iodine. Dilute acids easily convert it into glucose.

A substance closely related to, or perhaps identical with, everniin is obtained from *Borreria ciliaris*.

**EVERNINIC ACID**  $C_{12}H_8O_4$ . [157°]. Formed by decomposing evernic acid with caustic alkalis (Stenhouse, A. 68, 86; Hesse, A. 117, 299). Best prepared by boiling evernic acid with baryta water;  $BaCO_3$  is ppd., and the filtrate, treated with  $HCl$ , gives a pp. of everninic acid. Laminae, sl. sol. cold, m. sol. boiling, water, v. e. sol. alcohol and ether.  $FeCl_3$  colours its solution violet. Conc.  $HNO_3$  forms evernitic acid  $C_{12}H_5(NO_3)_3O_4$  or  $C_{12}H_5(NO_3)_4O_4$ ? which forms pale yellow prisms, sl. sol. cold, m. sol. boiling water, and forms a crystalline potassium salt  $C_{12}H_5K(NO_3)_3O_4$ ? (Hesse). Evernitic acid is perhaps di-nitro-everninic acid. Everninic acid differs from ever-

M M

nic acid in not yielding orcin when boiled with potash.

**Salts.**— $\text{Ba}(\text{C}_2\text{H}_3\text{O}_2)_2$  aq: long four-sided prisms, nearly insol. alcohol.— $\text{AgA}$ : white pp.

**Ethyl ether EtA**. [567]. From evernic acid by boiling for 9 hours with strong alcohol, or with alcohol containing KOH. Long colourless crystals (from alcohol), insol. cold, nearly insol. boiling, water, v. sol. alcohol and ether. Dissolves in aqueous KOH but not in aqueous  $\text{NH}_3$  or  $\text{K}_2\text{CO}_3$ .

**EXCREMENT.** Berzelius (*Lehrbuch*, [4] 9, 840) found in human faeces: water, 75.3 p.c.; bile, .9 p.c.; albumen, .9 p.c.; soluble organic matter, 2.7 p.c.; salts, 1.2 p.c.; insoluble residue of digested food, 7.9 p.c.; insoluble organic matter (mucous, bile-resins, and fat), 12 p.c. Human excrement, acidified by  $\text{H}_2\text{SO}_4$ , yields on distillation acetic, *n*-, and *iso*-butyric, valeric and caproic acids, phenol, indole, and skatole (from *skatols* = faeces) (Brieger, *J. pr.* [2] 17, 124). V. also Wehsarg, *Untersuchung der Faeces*, Giessen, 1853; Porter, *A.* 71, 109; Fleitmann, *P.* 75, 356; Marcet, *T.* 1854, 265; 1857, 403; *C. J.* 10, 162; Harley, *Pr.* 7, 122.

Thenard (*C. R.* 44, 980) found in fermented manure an acid  $\text{C}_{10}\text{H}_{15}\text{N}_3\text{O}_8$ , which may be ppd. from an aqueous extract by HCl. It is a black mass, insol. water, v. sl. sol. alcohol and ether.

**EXCRETIN**  $\text{C}_{10}\text{H}_{15}\text{O}$  (Hinterberger, *A.* 186, 213; cf. Marcet, *Pr.* 9, 308). Obtained by exhausting fresh excrements with boiling alcohol and leaving the solution to stand for a week. A black pp. then separates out, containing excretin and the salt  $\text{C}_{10}\text{H}_{15}\text{MgNO}_3$ . The filtrate is ppd. with milk of lime, and the dried pp. treated with a hot mixture of ether and alcohol. On exposing the solution during a week to a temperature below  $0^\circ$ , crude excretin crystallises out in semiglobular masses consisting of yellow needles. It is purified by crystallising it repeatedly from alcohol, with addition of blood-charcoal, the temperature being kept below  $0^\circ$ . Bromine converts it into di-bromo-excretin,  $\text{C}_{10}\text{H}_{13}\text{Br}_2\text{O}$ , which separates from a mixture of ether and alcohol in hard brittle crystals grouped in globular masses. A crystalline chlorine-compound could not be obtained. 100 pounds of fresh excrements yielded 8 grams of pure excretin.

**EXPLOSION.** If a system is in such a condition of physical or chemical equilibrium that a variation of that condition involving a transformation of energy, and initiated at any one point, will spread rapidly through the system of its own unaided action and without the supply of energy from without, then the system itself is said to undergo explosive change, and the change itself is called *explosion*. If the velocity of change is small the explosion becomes a combustion; if large, a detonation.

From considerations of economy of space the following account of the vast mass of work which has been done in connexion with the theory of explosions has been compressed as much as possible.

**EXPLOSION OF GASES.**—First really studied by Davy, and leading to the invention of the safety lamp; afterwards by Bunsen, Horstmann, Berthelot, Vieille, Sarrau, Mallard and Le Chatelier, Dixon, Clerk (*Gas Engine*, Longmans, 1887), and Von Oettingen and Von Gernet. The latter found (*W.* 4, 1888) that when a eudiometer tube is filled with water-gas ( $\text{H}_2 + \text{O}$ ) and explosion is induced by an electric spark, the luminosity is sufficient to enable a photograph to be obtained when the dust of some copper salt is distributed in the tube. By an ingenious combination of apparatus the flash can be reflected from a rotating plane mirror, and a real image of the analysed phenomena thrown on a sensitised plate (Eastman's negative) contained in a camera. It appears from a study of the picture obtained that the explosion is really very complex. The photographically active illumination does not occur till .001 sec. after the passage of the spark, this represents the time required for the copper salt dust to become luminous. The explosion, however, is shown to be practically over by this time. The photographs show waves of compression (indicated by excessive luminosity) to be travelling up and down the tube. There is also some indication (not convincing) of successive partial explosions taking place at periods of about .0001" to .0002". Bunsen has suggested (*P.* 1867) that the temperature at first attained is so high as to prevent complete combination, or in other words to cause dissociation of steam, and that as cooling takes place a number of secondary explosions occur until the combination becomes complete. These supposed suc-

cessive explosions are indicated by secondary wave-markings in the photograph. The explosive velocity appears to be about 2,800 metres per second, and the velocity of the pressure waves about 600 metres per second. If the temperature reaches 3000°C., as indicated by Berthelot, sound would travel through the gas with a velocity of 1,150 metres per second; the result therefore shows (assuming the reasons given for identifying the observed wave with waves of compression to be valid) either that 3000°C. is far too high a temperature, or that the displacements in the wave motion are such that the velocity is less than the velocity of sound, which is unlikely. Probably the conditions are such as to preclude any comparison with the velocity of sound under ordinary conditions; even supposing the adiabatic condition to be really fulfilled (but from the mere fact of the possibility of photographing we know this cannot be the case) there is room for great speculation as to the value of  $\gamma$ . Again, Kundt finds that powder in the tube has considerable effect even with small disturbances, and that in narrow tubes the velocity diminishes both with the diameter of the tube and with the wave length of sound (v. Rayleigh's *Sound*, vol. 2, pp. 26-54). Besides all this, the displacements are probably so large as to render the ordinary equations unavailable. The whole of the photographically luminous phenomena are over in .004 seconds. These researches, however, require confirmation.

The further stages have been investigated by other philosophers. In 1867 Bunsen published an account of some experiments he had made to determine the maximum pressure due to an explosion as well as the velocity with which explosion proceeds in gases. By estimating the heat produced during any explosion—which may be done from thermo-chemical data—and assuming that the specific heat of the products of combustion is either constant, or varies in some assumed way, it is clear that the maximum pressure produced may be calculated by assuming Boyle's Law or any modification of it—of course on the further assumption that no heat is lost from the exploding mixture before the maximum pressure is attained. Bunsen found that in certain explosive mixtures tested by him the theoretical pressure was never even approximately attained. The pressure gauge in Bunsen's experiments consisted of a sort of safety valve loaded to a known extent. Now it is clear, from the study of the equation of motion of such a valve, that much will depend on the period during which it is subjected to the high pressure; in fact to get a satisfactory result we ought to take into account the period of time during which the gases are rising to their real maximum of pressure. This period was an unknown quantity till Sarrau & Vieille and Berthelot determined it about twelve years later. However, Bunsen concludes from his experiments that the reason for the calculated maximum pressure not being attained in his apparatus is to be sought in the dissociation or rather postponed combination of the explosive gases. Bunsen also attempted to measure the velocity of combination by allowing the mixed gases to stream out by a narrow hole, and finding the least possible velocity which would prevent ex-

plosion running back into the reservoir. The assumption made is that when the velocity of efflux equals or exceeds the velocity of explosive propagation the flame will not run back. This we know cannot be true because of the conductivity of the material through which the jet passes; and besides this there is the cooling of the jet by expansion to be considered, tending to cause the rate of combination thus obtained to refer to gases at an undiscovered temperature. For water-gas Bunsen got a velocity of 84 metres per second, and for a mixture of equal volumes of carbon monoxide and oxygen he obtained the rate of one metre per second at atmospheric pressure. Mallard and Le Chatelier (*A. M. S.*, [1871]) show that for different mixtures the velocity becomes much smaller if an excess of one component is employed, or if an inert gas be present; they also show that much depends on the mode of inflammation. With the chemical ideas we shall have to deal later on. The real measure of the velocity, as well as of the later phenomena of combination, we owe to Dixon (*T.* 1884, 'On Conditions of Chemical Change in Gases'), to Sarrau and Vieille, and to Berthelot (*Berthelot, Traité sur la force des matières explosives*). The works in question are happily easily accessible, and therefore a mere summary will suffice here:—

1. The initial velocity of explosion depends on the diameter of the tube, on the pressure of the gases, on the initial mode of inflammation, and on the temperature of the mixture.
2. If the pressure is not too low and the diameter of the tube not too small, the reaction velocity will be accelerated, and will finally rise to a certain value which is henceforth pretty constant.
3. This velocity is independent of the nature of the material of the tube, and of its length, provided this is above the 'critical value' required to enable the so-called explosive wave to get established. The same remark applies to the diameter of the tube.
4. The velocity of the explosive wave does not depend on the pressure between the limits investigated, nearly to an atmosphere.
5. The influence of the chemical nature of the mixture is difficult to estimate, because in varying the composition, the disengagement of heat, and consequently the maximum temperature, varies. In fact the velocity approaches the velocity of molecular motion (of translation) calculated by Clausius and given by his formula

$$V = 29.354 \sqrt{\frac{T}{\rho}}$$

where  $T$  is absolute temperature on the thermodynamic scale, and  $\rho$  is the density of the gas referred to air (it is the density of the products of combustion that should be taken, but as unknown dissociation intervenes this is often difficult to estimate). The approximate agreement of this formula with the observed velocity suggests that very possibly it may afford a better means of measuring the real absolute temperature in the explosive wave than the thermo-chemical data actually employed. For although the same uncertainty exists as to the value of  $\rho$  we need make no assumption as to the specific

heat of the gases at the high temperature attained.

6. The explosive wave may be initiated at once by using a suitable detonator of mercury fulminate. Berthelot used fulminating electric interrupters to obtain registration on his chronograph. Dixon used similar interrupters without the fulminate, and found that Clausius' formula gave good results when the gases were wet. In fact the dryness or wetness of the gases is important for most mixtures, but not for water-gas. Berthelot and Vieille used a falling rod chronograph, Dixon a myograph. Dixon finds that in mixtures of carbon monoxide and oxygen the reaction products depend on the velocity of explosion, i.e. on the temperature obtained; carbon may even be deposited at high velocity. Similarly Berthelot and Vieille succeeded in completely decomposing acetylene into carbon and hydrogen by starting the wave with mercury fulminate. Finally Sarrau and Vieille (*C. R.* 105, 1222-4) find that the final equilibrium in many exploded gaseous mixtures depends on the pressure obtained; which in turn depends on the density of charge. Density of charge is

charge in grams

vol. available for explosion in cubic centimetres.

The following table will give an idea of the results obtained by Messrs. Berthelot and Vieille; the remarks are from Dixon's paper:—

Mixture	Sp. Grav. of products	Theoretical velocity absolute	Velocity calculated	Velocity found	Remarks
H <sub>2</sub> +O	•622	6780°	2831	2810	Wet or dry.
CO+O	1•429	6700°	1941	1089	Dry; when wet agrees better.
C.H. <sub>4</sub> +5O	1•227	1007°	2669	2452	
C <sub>2</sub> H. <sub>6</sub> +3O	1•075	7880°	2517	22•9	
C <sub>2</sub> N <sub>2</sub> +2O	1•343	9850°	2490	2195	Does not explode dry at ordinary pressures.

Mach and Wentzel (*W.* [1885] 26, 628) have investigated the velocity of decomposition of silver fulminate piled in a heap in free air. This they did by an ingenious method of firing two linear parallel heaps of fulminate on, or at the edges of, a plate of smoked glass. The heaps of fulminate were of equal length and were ignited simultaneously at opposite ends by the discharge of a Leyden jar. On examination, the smoked glass showed markings due to the motion of the air caused by the explosion. The authors note particularly a line which appears to be straight and inclined at an angle to the parallel heaps. This is supposed to be the line representing the locus of points of equal time with respect to the detonating heaps. If the velocity of the considerable aerial disturbance be taken at 400 metres per second, then by Huyghens' principle

$$V = \frac{400}{\sin \alpha} \text{ metres per second,}$$

where V is the velocity of ignition sought for. An experiment gave  $V > 1,700$  metres per second and  $< 2,000$  metres per second.

Notes as to chemical changes.—Bunsen, experimenting with a mixture of carbon monoxide,

hydrogen, and oxygen (too little for complete combustion), concluded that the ratio of water to carbon dioxide formed did not vary continuously, but by sudden jumps. Bunsen also found that the more rapid the combustion the more water and the less carbon dioxide was produced. Horstmann, by using pretty long tubes, got numbers from which he deduced a theory of the coefficient of affinity. Dixon discovered that for uniform results it is necessary that the pressure should be above the 'critical pressure.' This 'critical pressure' is the pressure beyond which length of tube has no effect on the result: it is higher the less explosive is the mixture. For instance, wet carbon monoxide with 12 p.c. of free oxygen has a 'critical pressure' of 400 mm.; if there is 19 p.c. of oxygen the 'critical pressure' falls to 200 mm. The 'critical pressure' is then the pressure above which the true explosion takes place. When the pressure is above the 'critical pressure,' and when the products of combustion are prevented from leaving the sphere of action by condensation or otherwise, and no inert gas is present to lower the temperature, and there is less hydrogen than twice the volume of the oxygen, then the coefficient of affinity (to be defined below) remains constant and is equal to 4; or in other words the ratio of burnt to unburnt gas is constant. A typical case is a mixture of carbonic oxide, hydrogen, and oxygen.

If H is the number of molecules of steam, H' the number of molecules of hydrogen, K the number of molecules of carbon monoxide at the beginning of the reaction, and K the number of molecules of carbon dioxide at the end of the

reaction, then  $\frac{KH}{KH'} = \alpha$  the coefficient of affinity.

For real information on these points the paper must be consulted. We can also do no more than refer to the very important experiments made by Mallard and Le Chatelier on the pressure produced by gaseous explosions (*A. M.* [8] 4, 272 [1883]). These philosophers used a Bourdon gauge indicator, and obtained a diagram showing the rate of cooling of the gases of explosion. The experiments of Clerk (*l.c.*) were directed to the practical application of gaseous explosions in gas engines; his apparatus consisted of a Richards' indicator with a drum travelling at constant speed; and his results are of a definite practical importance.

LIQUIDS AND SOLIDS. *General phenomena.*—For purposes of convenience the solid explosives are generally divided into two classes: one typified by gunpowder, the other by detonated gun-cotton. The first class is for the most part occupied by explosive mixtures; the second by explosive compounds. An accurate practical distinction may be made between those substances in which detonation may be produced as easily as in gun-cotton, say, and those in which it cannot be so easily produced. The general phenomena common to both classes of explosives are:—

1. A rapid chemical change attended by in

crease of volume and production of heat (this excludes such cases as the action of tartaric acid on sodium carbonate where heat disappears).

2. A dependence of the rate, and hence generally of the nature, of the decomposition on the greater or less facility which the products have for escaping from the seat of the reaction. This information we owe to Abel.

3. If the substance is inclosed in a confined space the final pressure of the products will depend on the ratio of the volume of the space to the volume of the explosive substance; on the heat produced during the reaction; on the nature of the reaction as influenced by the escape of the products; on the greater or less dissociation of the products; on the physical state (solid, liquid, or gaseous) of the products at the temperature of the explosion; on the relation of the velocity of cooling to the velocity of the reaction; and finally on the mode of inflammation in relation to the initial temperature.

We may at once premise that explosives of the second class differ essentially when 'detonated' from explosives of the first class, in that their reaction is analogous in point of velocity and means of propagation to the explosive mode of 'decomposition' observed in gases by Berthelot and Dixon.

It is immaterial whether the reaction by detonation or explosion of the 'first order,' as it is sometimes called, is brought about by a detonator of some other sudden explosive, or whether it is produced by the gradual rise of temperature and pressure produced by the products of the decomposition of some other part of the same mass. A detonation of gun-cotton may be produced equally well by using a detonator of confined fulminate of mercury, and preventing the escape of the products of combustion, or by igniting a portion of the gun-cotton by the application of a hot body or flame.

Many substances detonate or not according to the circumstances in which they are placed. Fulminate of mercury, for instance, piled in small quantities on a sheet of iron may be inflamed by a wire laid on the top without producing a much greater explosion than would be produced by gunpowder under similar circumstances. If the wire is placed beneath the heap and heated by a current to a sufficient temperature the slight resistance to the escape of the products of combustion first formed will be sufficient to convert the puff into a loud detonation, which bruises the plate.

It is very easy to get the explosive wave established in fulminate of mercury, and in fulminate of silver and iodide of nitrogen it is difficult to prevent it becoming established. (In some of Abel's experiments on the transference of exploding influence through tubes it was noted that the fulminate of silver did not explode with its usual violence.) In the nitroglycerin compounds the relative ease or difficulty of establishing an explosion of the first order, i.e. detonation, depends largely on the physical state of the substance. In all cases what is required is that the pressure on, and the temperature of, a portion, no matter how small, of the substance to be exploded, shall rise above a certain critical value which depends on the nature, initial temperature, and physical state, of the substance. It is not

necessary to make any hypothesis such as that long since suggested by Abel as to 'synchronism of vibration,' the anomalies which it was framed to account for having either arisen from misapprehension, or having been accounted for in other ways.

We proceed to the general theory.

Provided the reaction is complete the heat given out may be obtained from the thermochemical data which we owe to Berthelot. A little care is requisite here, because it generally happens that some of the products of combustion are liquid at ordinary temperatures. Now if we wish to determine the maximum pressure, this will involve a knowledge of the heat of combustion when all the products are kept gaseous. Sometimes it may happen that a reaction taking place at high velocity is not identical with that at the velocity actually attained in the necessary calorimetric experiments. In such cases we must make sure (by analysis of the products) either that the reaction has not changed, or if it has, due allowance must be made in the thermochemical data. A much greater difficulty arises in estimating the percentage of combination which has occurred when the maximum pressure is reached. We may either introduce a correction (if one is to be found) in the data for the heat of reaction, or in the data for the specific heat of the products. It will be convenient to assume, with the higher explosives at all events, that the maximum pressure is reached before any heat is lost to the containing vessel. It will also be important to note that a decomposition-reaction taking place at constant volume may not be identical with the reaction at constant pressure. With the higher explosives the reaction even in the open air is more nearly at constant volume than at constant pressure.

If  $Q_v$  is the heat of the reaction available for raising the temperature of the products at constant volume, and  $Q_p$  is the corresponding number at constant pressure, and if the volume of gas liberated is known, then  $Q_v = Q_p +$  thermal equivalent of work done in overcoming external pressure. For instance, for 227 grms. of nitroglycerin  $Q_p$  will be 356.5 kilogram-degrees, and  $Q_v$  360.6 kilogram-degrees. The volumes of the gases of combustion being supposed to be reduced to 0° and to expand against a pressure intensity of one atmosphere,  $Q_v$  comes to 1,590 gram-degrees per gram of nitroglycerin at an initial temperature of 15°C. Sarrau and Vieille found by a calorimetric experiment 1,600 gram-degrees. To take a simple case: Suppose the thermal value of the reaction ( $Q_v$ ) can be obtained for a gram of substance, let this quantity of substance be inclosed in a space of  $v$  c.c., and suppose its own volume negligibly small in comparison; let the products of reaction, supposed still gaseous and obeying Boyle's Law, occupy a volume  $v'$  at 0° and 760 mm.; let the specific heat of the product supposed constant be  $\sigma$ , and let  $m$  represent the ratio of the portion burnt to the whole initial amount at the epoch of maximum pressure  $P$ , then the formula will become

$$P = \frac{v'}{v} Q_v \frac{m}{\sigma}.$$

Now it is clear that as this calculation is

based on Boyle's Law, the temperature being considerable, we must expect a merely approximate result, according to Amagat's experiments at high temperatures and pressures. Again our knowledge of  $\sigma$ , a quantity which is possibly dependent on the pressure and temperature, is mere guess work, and the same may be said for  $m$ . The only at all satisfactory case is that of fulminate of mercury ( $\text{HgC}_2\text{N}_2\text{O}_6$ ), the products being  $2\text{CO}$  and  $\text{N}_2$ , a mixture not very susceptible of dissociation, though Dixon noted that even  $\text{CO}$  is decomposed at high velocities. Berthelot shows that the effect of dissociation is in all cases to lower the pressure, the heat used being without exception insufficiently compensated by the increased volume of the gas liberated. For speculation as to the probable value of  $P$  from theoretical considerations the reader is referred to Berthelot. We shall describe the practical way in which the pressure is measured, and content ourselves with pointing out that Berthelot's theory leads to results which sometimes (according to his success in guessing  $m$  and  $\sigma$ ) do not differ widely from the experimental results. Of Berthelot's experiments it is impossible to speak too highly.

The instrument used in measuring pressures is based on the crusher gauge invented by Rodman, and improved by Noble and by Abbot; the former by the introduction of a cylindrical crusher and copper cylinder, the latter by the addition of a clutch making its use possible under water. For our purpose the best experiments are those of Sarrau and Vieille, for to them belongs the honour of having rightly interpreted the indications afforded by the gauge. The difficulty of interpretation will be best understood after a short description of the normal type of crusher. This instrument consists essentially of a hollow cylinder of mild steel, strengthened, if necessary, externally by winding with wire. The cylinder is open at one end and closed at the other by a strong screw plug; the explosive to be investigated is placed in the hole and usually rests near the plug; the electrical firing arrangements pass through the plug itself. The capacity of the instrument used by Sarrau and Vieille was about 24.83 c.c., and the diameter of the bore was 2.2 centim. A ram piston is inserted into the open end of the bore, and is supported at its outer end by a cylinder of pure copper, which in turn rests on a massive anvil braced to the rest of the apparatus. The instrument is strengthened by two plates, one at each end, braced together by strong bolts. The dimensions of the soft copper cylinder are accurately determined by a previous experiment, and the charge is weighed and introduced below the plug, the volume of the bore down to the piston head being accurately measured. On firing, the increase of pressure due to the explosive gases causes the piston ram to 'crush' the copper cylinder. The problem is to find the maximum pressure exerted on the cylinder. In Rodman's instrument the piston was furnished with an indenting tool, and the apparatus itself was of slightly modified construction, being screwed into a gun and the piston being acted on directly by the explosion of the gunpowder when the gun was fired. Rodman's interpretation was based on experiments made with a testing machine. His

assumption was that the dimensions of the 'cut' of the copper depended on the maximum pressure; the calibration was effected by producing an equivalent cut in a testing machine and measuring the pressure at which it occurred.

This is rightly criticised by Abbot, who adopts a rather different method. He uses a solid cylinder of lead and crushes it by means of a flat-headed piston. If the length changes during the operation from  $L$  to  $L'$ , and if  $P$  is the mean resistance of the lead cylinder to deformation, then the work done is

$$W = F(L - L').$$

$W$  is next measured by the fall of a hammer head pendulum. The distance through which the pendulum falls is so arranged that it produces the same crush as that observed in an experiment. In Abbot's case the pressures measured were pressures of explosion under water, and his apparatus therefore more resembled Rodman's. The kinetic energy of the blow being known, and the assumption being made that all the energy is effective in producing the crush, or, what comes to the same thing, that the effectivity is the same during the hammer-blow (he does not say this) as it is during the experiment—we have a means of obtaining in the first case an absolute measure of  $W$ ; in the second a measure proportionate to  $W$ .

It is clear, therefore, that if the resistance is a known function of the length we shall be able to obtain a value for  $F$  leading to a true result. As a matter of fact the process of 'crush' is complex, the resistance being very different before and after flow takes place.

It is probable that in the immense deformations employed by Abbot the chief resistance is resistance to flow, and this will to a certain extent depend on the velocity of flow. In other words, his calibration is inexact unless the piston of the crusher moves with the velocity of the hammer.

The explosion endues the piston with kinetic energy, and this energy is spent in deforming the cylinder. It is clear at once that much will depend on the time required for the pressure to reach its maximum considered in connexion with the mass of the piston. Sarrau and Vieille (*C. R.* 95, 26, 130) use copper cylinders in connexion with the instrument described above. The equation of slow crush in the testing machine is

$$T = K_1 + K_2 \epsilon,$$

$\epsilon$  being the crush, or change of length produced,  $K_1$  and  $K_2$  constants, and  $T$  the pressure producing the observed crush. If the crush is not very great, and the rate of crush slow,  $K$  seems fairly constant up to pretty high values. It by no means follows, however, that the case is the same if the velocity of flow be great. When the cylinder is crushed by one explosion two extreme cases have to be considered.

1. The piston may be so light that the pressure of the explosion is transferred to the copper cylinder practically at the time of its development in the explosion cylinder.

2. The explosive pressure is so rapidly produced, or the piston is so heavy, that the maxi-

<sup>1</sup> Of course in the end all the energy, or nearly all, is converted into heat in the cylinder and neighbouring surfaces.

mum pressure is reached before the piston begins to move.

In practice of course there are intermediate cases. Let  $p=f(t)$  be the variable pressure at the base of the piston,  $m$  the mass of the piston,  $R$  the resistance of the cylinder,  $u$  the displacement of the piston after time  $t$ . Neglecting the compression of the piston, &c., the equation of motion is

$$m \frac{d^2u}{dt^2} + R = f(t),$$

within the limits  $R=K_0$  to  $Ku$ . Neglecting the work done within the elastic limits of the cylinder, and taking care that the charge is of such a size as not to cause the crush to pass the limit for which the equation holds, this becomes

$$m \frac{d^2u}{dt^2} + K_0 + Ku = f(t).$$

This may be integrated, and when the pressure passes through its maximum  $P$ , we get a relation between this maximum and the final crush of the cylinder. This solution is of the form

$$P = K_0 + \frac{K\epsilon}{1 + \phi\left(\frac{t}{t_0}\right)},$$

$t$  being the time from the origin to the epoch of maximum displacement, and  $t_0$  the period of crush of the cylinder under a constant force acting without initial velocity through the mediation of a piston of equal mass  $m$ ;  $\phi$  is such a function that it is unity when the variable vanishes, and decreases rapidly as the variable increases. So the value of  $P$  depends on our knowledge of  $\frac{t}{t_0}$ , and this must be determined in each case.

Now,  $t_0$  is given by

$$t_0 = \pi \sqrt{\frac{m}{K}};$$

it is the period (or, as we should say, half period) of the piston.  $t$  is got by actual measurement: this is accomplished by allowing the piston to carry a style pressing on a chronograph drum.

In a general way the ratio is found to vary according to the mass of the piston employed. Sarrau and Vieille, however, prefer so to vary the mass of the piston that one or other of the extreme conditions is fulfilled. If the pressure rises slowly (within the sense of the equation) then

$$P = K_0 + K\epsilon.$$

If, on the other hand, the piston moves under constant force,

$$P = K_0 + \frac{K\epsilon}{2}.$$

Some interesting cases present themselves.

When  $\frac{t}{t_0}$  varies between 4.8 and 251, the crush remains the same (or nearly so) with powder, showing that with the piston used the first equation must be employed. With potassium picrate, on the other hand, no sensible value can be assigned to  $t$ , and the second condition is fulfilled. The same remark applies to gun-cotton and fulminate of mercury; with dynamite, on

the other hand, we have an intermediate case.

The first condition is wholly unattainable in practice, and the second only when the mass of the piston is very great (in the experiments of Sarrau and Vieille it was 4 kilos.). If the piston had a mass of from 3.8 to 6.9 grs. only, then the crush for a given quantity of dynamite was only half what it was when the crush was given by the heavy piston; for intermediate values of the piston weight the crush was also intermediate.

With the exception, therefore, of the difficulty above mentioned as to rate of crush, we may consider that Sarrau and Vieille's experiments establish the right of the crusher to consideration as an instrument of precision. It must not be forgotten, however, that the indications afforded refer to mean maximum pressures only. There may be much local variation at points near the centre of explosion. By considering the nature of the possible means of escape of the gaseous products, it appears that vortex motion and jet motion may be set up. This was noticed by Threlfall (*P. M.* 1886) in the case of small explosions of fulminate of mercury under water, by Abbot in the case of large submarine dynamite explosions, and by Berthelot as a result of his general experience. The latter notes that metals subjected to the influence of detonating compounds are 'creusés et sillonnés,' and referring to the seat of such explosions he remarks: 'En réalité, les gaz brusquement développés par la réaction chimique représentent de véritables tourbillons, dans lesquels il existe des filets de matière sous des états de compression très différents, et une fluctuation intérieure.'

It will be evident that there is much difficulty in answering such a question as 'What is the strongest explosive?'—in fact, no answer can be given unless the conditions of explosion are specified. We may arrange explosives in the order of maximum pressures developed per unit mass in unit volume in a crusher gauge, or we may construct a table showing the pressures produced by unit masses in their own volumes, or by equal volumes in their own volumes. For instance, in the case of fulminate of mercury with an actual density of charge at the rate of 3 g. per c.c., the crusher indicates a pressure intensity of about 6,000 kg. per sq. centim. for unit density (the standard condition). For cotton-powder the figure mounts to 10,000 kg. per sq. centim. If, however, we consider equal masses of these substances exploding in a space just capable of containing them, the mercury fulminate (thanks to its specific gravity of 4.42) will produce the enormous pressure of 27,000 kg. per sq. centim., while the number for the cotton powder will be only slightly increased. Now detonators in practice consist of confined charges in copper or tin tubes, and therefore it is clear at once why fulminate of mercury is the detonator *par excellence*, even though the energy expended per unit mass is surpassed by other explosives. The period of the attainment of the maximum pressure of detonating substances, excepting nitro-glycerin compounds, may be taken as less than  $\frac{1}{1000}$ th of a second.

Fulminate of silver, though so remarkable as a violent explosive, fails as a detonator through lack of density. The peculiarity of it, and of

iodide of nitrogen, lies in the ease with which the explosive wave can be established in them, rather than in the energy run down by a given volume, which is the practically important point. With respect to the uncertainty in the method of calculation referred to at the beginning of this article, it seems as if the very high temperature in the crusher gauge tends to counteract the uncertainty produced by the enormous pressures. We give the following example of the actual calculation in the case of fulminate of mercury:—

The heat of formation of

$\text{O}_2\text{N}_2\text{O}_2\text{Hg}$  (= 284) is 114,500 gram-units.

Deducting the heat of vaporisation of mercury, this comes to 114,500–15,400=99,100 units available. Taking 4·8 as the molecular specific heat at constant volume of the mercury vapour, the carbon monoxide, and the nitrogen, and neglecting the difference between this value and the value for liquid mercury, then

$$T = \frac{99,100}{4 \times 4.8} = 5,161^\circ.$$

The volume of gas formed (CO+N) reduced by the ordinary assumption to  $0^\circ\text{C}$ . and 760 mm. will be 22·32 litres. At a temperature  $5161^\circ$  (taking into account the volume of gaseous mercury) we shall have under normal pressure

$$V = 22.32 \left(1 + \frac{5,161}{273}\right) = 1,776 \text{ litres}$$

as the quantity of gas given off by 284 g. of fulminate in a certain crusher experiment.

Now, 10 g. of fulminate were actually fired in a space of 50 c.c.; the corresponding space for 284 g. would have been 1·42 litres, so by Boyle's Law the pressure would be

$$\frac{1,776}{1.42} = 1,251 \text{ atmos.}$$

or 1,293 kg. per sq. centim.

The experiment in the crusher gave  $e = 2.4$  mm., and the time of reaching the maximum was negligible. Therefore (the constants being previously known)

$$P = 641 + 535 = 1,176 \text{ kg. per sq. centim.}$$

Comparing these two numbers we get an idea of the closeness of the results; they agree to within about 10 p.c. The deviation may be due either to the error introduced by the flow of the copper or by any of the assumptions in the theory. The gauge-estimate is probably the more correct.

The following notes may be of service. It is well known that many of the more rapid explosives do not require any tamping—i.e. a charge of gun-cotton simply laid on a rock will do nearly as much work in breaking and shattering as if it were covered with sand or clay-tamping. The reason is that the increment

of volume tends to take place with greater velocity than that with which sound is propagated through air. Consequently it may happen that the pressure rises above the crushing strength of the rock, in which case fracture will result. In order to produce any appreciable effect at all the velocity of explosion must be above some critical value; when this is surpassed the amount of destruction performed will depend on the energy available.

It is a well-known fact that a small charge of fulminate of silver fired on a card or thin sheet of glass will in general blow a hole through the card or glass without doing other damage. The cause of this phenomenon has been sought by several observers, the most reasonable of whom appear to be Mach and Wentzel (*l.c.*), who begin by showing that the same effect can be observed in a vacuum. This leads them to measure the velocity of escape of the gases formed during explosion, by observing their effect on hollow cups forming convenient portions of a ballistic pendulum. The resulting velocity turns out to be between 3,500 and 17,500 metres per second, with a probability that the lower limit is the one most nearly approached. The authors argue that the density of the gases evolved with this velocity must be very considerable, and hence that the effect on an obstacle must be comparable with the effect produced by the impact of a projectile. This leads to the interesting question of what occurs when a soft body is caused to penetrate a hard one in virtue of its high velocity, as when a tallow candle or bit of soft wood is shot through a door.

The so-called 'sympathetic explosion' of charges probably does not exist. Cartridges both of gun-cotton and dynamite may be shattered to dust by an explosion without being ignited. Detonation may be produced equally well in chemical compounds and in mixtures, such as that of dinitrobenzene and potassium chlorate; in either case all that is required is that the pressure and therefore the temperature should rise to a sufficient value at any one point of the mass.

The ease with which detonation may be brought about will depend *ceteris paribus* on the physical state of the explosive as to hardness, fluidity, &c. The most powerful—i.e. energy-liberating—explosive per unit volume is fulminate of mercury; the most powerful per unit mass is blasting gelatine (92 p.c. nitro-glycerin and 8 p.c. nitrocellulose [the exact composition of the particular nitrocellulose is not stated]). The latter, owing perhaps to its physical state, is most difficult to detonate except in hard rock. For detailed information on matters connected with explosions the reader is referred to Berthelot. B. T.

## F

**FAGINE.** An alkaloid said to occur in beech-nuts (Buchner & Herberger; Habermann, *C. O.* 1884, 789; *J.* 1884, 1445).

**FAT.** The term fat was originally applied to all compounds of carbon, hydrogen, and oxygen, which leave a permanent grease-stain on paper. They were divided into solid fats and fatty oils, the latter being subdivided into drying and non-drying oils. Chevreul showed that most natural fats are mixtures of olein, stearin, and margarin, the last body being subsequently proved by Heintz (*A.* 80, 293; 84, 297) to be a mixture of stearin and palmitin. Chevreul also showed that on boiling with potash the potassium salts of oleic, stearic, palmitic, or other acids, are formed as soaps, while glycerin is in most cases also produced. Chevreul classes paraffin and cholesterol as unsaponifiable fats, the other fats being saponifiable. The term fat is, however, usually confined to saponifiable bodies.

**Preparation.**—Fat is obtained from animal tissue by melting at 100°. The membranous portions may be removed by adding 1 pt. of very dilute HCl (containing .03 pts. HCl of S.G. 1.12) to every 10 pts. of the raw fat, and heating in a water-bath (Pohl, *D. P. J.* 201, 254). The rancid odour often acquired by keeping is due to volatile fatty acids, which may be distilled off in steam by boiling with water (Dubrunfaut, *C. R.* 72, 37). The odour may also be removed by treatment with aqueous  $\text{Na}_2\text{CO}_3$ . Vegetable fatty oils are expressed from seeds; a second quantity may be got by grinding up the seeds and pressing them a second time while hot. Nitrogenous substances are removed from the oil by shaking with 1 p.c. conc.  $\text{H}_2\text{SO}_4$ . Fats are also extracted from animal and vegetable products by benzene.

**Properties.**—Solids or liquids, lighter than water, cannot be distilled. Insol. water, v. sol. ether,  $\text{CS}_2$ , benzene, and light petroleum; sol. alcohol. When strongly heated they give off a pungent odour of acrolein. Alcoholic  $\text{NH}_3$  slowly converts the fats in the cold into glycerin and amides of the acids (Rowney, *J. pr.* 67, 157). Nitric acid oxidises fats, forming oxalic, succinic, and adipic acids. Nitrous acid causes oils which contain olein to solidify through the isomeric change of that liquid to solid elaidin.

**Saponification.**—Fats are broken up into glycerin and fatty acids by treatment with superheated steam, or by boiling with aqueous alkalis with water and  $\text{PbO}$ , or with dilute  $\text{H}_2\text{SO}_4$  (cf. Benedikt, *M.* 9, 518). Saponification may even be effected at 45° by agitation of the melted fat with aqueous  $\text{NaOH}$  containing  $\text{NaCl}$  (Mège-Mouriès, *C. R.* 68, 864; Legrand, *D. P. J.* 186, 151; Knapp, *D. P. J.* 180, 304; 192, 498; cf. De Milly, *D. P. J.* 186, 145). Saponification may be conveniently effected by heating with lime (3 p.c.) and water at 172°, or with  $\text{H}_2\text{SO}_4$  (8 p.c.) at 115°, glycerin being distilled off with superheated steam.

**Drying Oils.**—These oils become solid through atmospheric oxidation. This tendency is increased by previous boiling with  $\text{PbO}$ . Linseed

oil is the chief drying oil; it contains glyceryl linoleate.

**Estimation.**—The amount of fat in a mixture is determined by extracting with ether, and evaporating the extract. The amount of free fatty acid may be determined by titration (Stohmann, *J. pr.* [2] 24, 510; Hausmann, *Fr.* 21, 447; Groger, *Fr.* 22, 289; Knebel, *Fr.* 23, 261). The molecular weights of the higher alcohols and of the oxy-acids present in fats have been determined by forming their acetyl derivatives and then saponifying these bodies by alcoholic potash and titrating the excess of potash, using alcoholic phenol-phthalein as indicator (Benedikt & Ulzer, *M.* 8, 41).

**Composition.**—The following fats and fatty oils, amongst others, contain olein, stearin, and palmitin: fat of men, sheep, oxen, geese, and pigs, of cantharides, cocoa beans, oil from seeds of species of *Bassia*, from Para nuts, from *Cocculus indicus*, and from maize. Olein and palmitin occur in cotton-seed oil, in bichyba fat, in palm oil, in the fat of beans, peas, and lupine seeds, and in elephants' fat. Oil of rape and of mustard seeds contain glycerides of erucic and benenic acids. Earth-nut oil contains glycerides of palmitic, arachic, and hypogaeic acids. Cocoa-nut oil contains glycerides of formic, acetic, butyric, hexoic, octoic, deoic, lauric, myristic, and palmitic acids. The fat from the seeds of *Anacardiaceae* contains olein and stearin. Croton oil contains glycerides of formic, acetic, isobutyric, isovaleric, tiglic, palmitic, stearic, lauric, myristic, and oleic acids. Almond oil consists almost entirely of olein. Nutmegs contain myristin. Castor oil contains glycerides of stearic and ricinoleic acids. Linseed oil consists chiefly of the glyceride of linoleic acid, but contains also those of palmitic and myristic acids. Cod liver oil consists chiefly of olein and palmitin, but it contains also small quantities of acetic and butyric acid and some compound of iodine. The oils from poppy seeds and from walnuts contain glyceryl linoleate and other glycerides. Butter contains glycerides of palmitic, stearic, myristic, arachic, butyric, hexoic, octoic, and deoic acids.

## FATTY ACIDS v. ACIDS.

## FATTY ALCOHOLS v. ALCOHOLS.

**FATTY COMPOUNDS.** This term is applied to all organic compounds whose molecules are supposed not to contain a closed chain of carbon atoms.

**FEHLING'S SOLUTION.** An alkaline solution of potassium-tartrate of copper used in the estimation of glucose, which reduces the solution with ppn. of red  $\text{Cu}_2\text{O}$ . Fehling (*A.* 72, 106; 106, 75) dissolves 192 grams  $\text{NaK}_2\text{C}_4\text{H}_4\text{O}_6$  crystals in a little water, adds 600–700 c.c.  $\text{NaOH}$  aq. S.G. 1.12, and then 40 grams  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  in about 160 c.c. water, and dilutes to 1154.4 c.c. at 15°. Five milligrams of dry glucose ppt. all the  $\text{Cu}$  as  $\text{Cu}_2\text{O}$  from 1 c.c. of this solution.

M. M. P. M.

**FELLIC ACID  $\text{C}_{22}\text{H}_{40}\text{O}_4$ .** [120°]. An acid said to accompany cholic acid in human bile

(Schotten, *H.* 11, 268). Strongly electrical powder, tastes bitter. It gives a red, but not a crimson, colour with Pettenkofer's test.— $\text{BaA}^1$ , 4aq. S. 1.3.— $\text{MgA}^1$ , 2, aq.

**FENNEL OIL.** The oil of common fennel (*Anethum Feniculum*) contains anethol and a terpene (phellandrene) (c. 187°) (Cahours, *A.* 41, 75).

#### FERMENTATION AND PUTREFACTION.

Most organic compounds exposed to the air undergo decomposition at a more or less rapid rate. The decomposition takes place most rapidly in the presence of moisture and at a slightly elevated temperature. In most cases the decomposition consists in the breaking down of complex molecules either by the assimilation of the elements of water (*hydrolysis*) or by a slow process of oxidation (*eremacausis* or *decay*). In other cases the change seems to be one of molecular rearrangement resulting in the alteration of the physical properties of the body, such as the conversion of a solid into a liquid metamericide. When these changes are accompanied by the evolution of gases of unpleasant odour, the term *putrefaction* is used, and it may therefore be regarded as a special case of fermentation. The earliest experiments on these phenomena have established the facts that decomposition does not take place if air be excluded, if the materials be dry, if the temperature be below 0°C. or above 100°C., or in the presence of certain organic and inorganic bodies, which, from having the property of arresting or preventing these changes, are called anti-septics, anti-ferments or anti-putrescent substances. Formerly it was held that these changes were due entirely to the action of chemical and physical forces, but it is now known that in most cases, and possibly in all, the decomposition cannot take place without the intervention of living organisms or of chemical substances, which, although of an unorganised constitution, are derived directly from living protoplasm. The bacteria and certain fungi are the best-known organisms which determine these changes. Each bacterium characterised by its particular form and growth feeds on a particular pabulum or chemical food causing it to break up and form definite chemical products, so that there is found in each kind of fermentation the same conditions and the same kind of organism. The reasons which have led to the above view are based not only upon the conditions which are found necessary for the fermentation to take place but also upon the fact that a nitrogenous body is always found in the liquid even when the chemical change consists in the breaking down of a non-nitrogenous compound. In some cases fermentation is brought about in a manner which appears to be different from the foregoing, no organisms being present, and the addition of certain anti-ferments fail to stop the decomposition. In these cases bodies of complicated constitution, and directly derived from vegetable or animal organs, must be present. They are without organic structure, and are known as chemical or unorganised ferments or *enzymes*, and may in most cases be extracted from the organs in which they occur by means of glycerin, and can subsequently be precipitated from the solution in an amorphous condition by the addition of alcohol. The enzymes seem to be an

intermediate product of organic life. None have been prepared artificially, and plant and animal organs by the secretion of these substances are enabled to perform their special functions. Their characteristic properties are destroyed when their aqueous solutions are warmed to a temperature near to 100°C., and no action takes place when the solution is cooled below another fixed temperature. These critical temperatures vary with the different enzymes, but the range of temperature approximates to 50°–75°C. Great concentration of the solution and the addition of glycerin or alcohol alter the temperatures at which the enzymes cease to act. Dry enzymes can be heated to the boiling-point of water and even higher without destroying their property of fermenting. Dried pepsin can be heated to 170° without losing its fermenting action (Hüppe, *C. C.* 1881, 745). Light also modifies the rate at which the enzymes ferment.

**Theories of fermentation.** From the fact that contact with air and the presence of a nitrogenous body are necessary for fermentation or putrefaction to take place, Berzelius and Liebig concluded that the nitrogenous matter was decomposed by the atmospheric oxygen, and that this reaction caused a rearrangement of its elements which determined the decomposition of the molecules of the fermentable substance present. Schwann's discovery of the presence of organic germs in the air led Pasteur to formulate the theory that fermentation is never excited except under the influence of microscopic organisms, and further that each particular organism sets up a peculiar species of fermentation. Schwann and Helmholtz showed that air which had passed through a red-hot tube could not induce fermentation, and thereby proved that oxygen alone was not sufficient to bring nitrogenous matter into the condition of a ferment. Blondeau was the first to show that the conversion of sugar into alcohol was due to the growth of one particular organism (*Torula cerevisiae*), and that the conversion of sugar into lactic acid was due to the growth of the mould *Penicillium glaucum*, and that beer yeast contained the germs of both these organisms. Blondeau also pointed out that in butyrous fermentation or the formation of butyric acid from sugar, and in the conversion of urea into carbonate of ammonia, a growth of *Penicillium glaucum* accompanied the change. These views of Blondeau, Pasteur, and Schwann, were contested by Liebig, who adduced experiments in support of his own view. Schmidt (*A.* 61, 168) pointed out that by adding the clear filtrate from the paste produced by beating almonds with water to a liquid containing urea or grape sugar, fermentation took place, and when the latter substance was employed, no trace of yeast cells was manifest until the fermentation had taken place for a considerable time. Pasteur (*Bl.* 1861, 87–79) produced additional evidence to show that ready-formed yeast would germinate and grow to a limited extent in a liquid containing sugar and albuminous matter, even when oxygen was completely excluded. He explained this result by assuming that the yeast acted as a ferment in the absence of air by abstracting oxygen from the sugar, and that upon this deoxidising power its action as a ferment

**depende.** Organisms which are aerobic, and live by means of the oxygen of the air, might become anaerobic and derive their oxygen from some ready-formed compound and thus act as ferments. Pasteur also extended his researches on the action of ferments to the phenomena of putrefaction and decay, and (*C. R.* 56, 734, 1189) defined putrefaction as a kind of fermentation induced and maintained by organisms of the genus *Vibrio*, which can only live in contact with the air. He showed that when calcium lactate ferments in the absence of air, calcium butyrate and other products are the final result, whilst, if air has access to the liquid, the butyrate likewise ultimately disappears. The putrefaction of solid bodies (animal carcasses) is also due to the activity of these organisms, whose development can be checked by inclosing the substance in a closed vessel containing a cloth soaked in spirit or by other antiseptic treatment. The gangrene which is subsequently produced under these conditions is regarded by Pasteur as distinct from putrefaction, and as analogous to the ripening of fruits after their separation from the plant on which they grow. These experiments of Pasteur were criticised by Lemaire (*C. R.* 57, 958), who regarded the various processes of fermentation as due to the action of one and the same ferment, and denied the existence of special ferments. He also concluded that the unrestricted access of air was essential to the progress and completion of putrefaction. Pasteur (*C. R.* 73, 1419) drew attention to the fact that properly selected mineral salts were necessary for the growth of fermentative germs. He found that the addition of small quantities of  $\text{NH}_4$ , Mg, Ca phosphates and  $(\text{NH}_4)_2\text{SO}_4$  to a solution of calcium lactate increased the rate at which the lactate disappeared on the addition of vibrios, and that at the same time numerous fresh vibrios were produced. As soon as the whole of the lactate was decomposed the vibrios fell dead to the bottom of the vessel. Again (*C. R.* 75, 784) he showed that the same cells acquire or lose the power of acting as a ferment according as they are deprived of air or exposed to its action. Yeast and other ferments can therefore live and multiply without contact with the atmosphere by obtaining the oxygen necessary for their existence from the decomposition of the oxygenated compounds in which they live. The moulds, such as *Penicillium glaucum*, become ferments when they feed in this manner upon bodies rich in oxygen instead of absorbing atmospheric oxygen. Evolution of heat usually accompanies fermentation; the compounds, which are decomposed, being of a high order of complexity, evolve heat in their resolution into simpler molecules of a more stable nature. The spontaneous combustion of some organic bodies is probably due to the action of ferments. Bodies rich in nitrogen are very prone to putrefaction, but some, such as uric acid, the alkaloids and indigo, do not undergo any change. The gases evolved in fermentation may be carbonic acid, ammonia, sulphuretted hydrogen, hydrocarbons, nitrogen, and hydrogen. Bernard drew attention to the fact that fruits exposed to an inert gas evolve carbonic acid, and Pasteur showed that alcohol was at the same time produced which pointed to a sort of fermentation taking place. The earlier experiments

on the action of reagents upon ferments showed that neutral gases and dilute acids do not affect the power of yeast, but that sulphur is reduced to sulphuretted hydrogen when added to a fermenting liquid. Dilute alkalis retard fermentation and large doses of dilute acids completely stop it. The behaviour of other reagents upon fermenting liquids is discussed under *antiseptics* at the end of the present article. The influence of pressure on fermentation has been studied by H. T. Brown (*C. J.* [2] 10, 570; 11, 973). According to his experiments, N, H, paraffin hydrocarbons, and NO are evolved, besides  $\text{CO}_2$ , in the alcoholic fermentation of grape sugar or malt wort. Diminution of pressure causes a large increase of the gases unabsorbed by KHO. The increase of hydrogen is accompanied by the formation of acetic acid and aldehyde, and no nitrogen is evolved from solutions free from albuminoids. The nitric oxide is due to the reduction of nitrates under diminished pressure, less sugar is decomposed, and the proportion of carbonic acid to alcohol is greater. The influence of temperature on fermentation has been studied by many observers chiefly from an industrial point of view. Pierre (*C. R.* 73, 317) showed that high temperatures in alcoholic fermentation were attended with a more abundant formation of the higher alcohols. When the temperature is kept down to the lowest point, traces only of butyl and amyl alcohols are obtained. Propyl alcohol is always produced. Contributions to the study of fermentation by Brefeld (*B. J.* 281), Mayer (*B. J.* 579) and Traube (*B. J.* 872) conclusively proved that yeast requires for its growth and propagation free oxygen. Fermentation takes place in the absence of free oxygen, but in this case the yeast does not increase. Moritz (*C. J.* 1874, 599), Mohr (*B. J.* 1421) and Pasteur (*C. R.* 80, 452) disagree with their results, and still more recently Berthelot has published the laboratory notes of C. Bernard which tend to support the observations of the former experimentalists. According to Bernard (*C. R.* 87, 125), alcoholic fermentation is not life without air, for alcohol is formed by contact of sugar with air without yeast. The ferment is not derived from external germs, for in sterile juices the ferment is not developed; alcohol is formed by a soluble ferment apart from the life of the ripening fruit for which air is absolutely necessary. The soluble ferment is found in the juice expressed from the fruit, and it produces alcohol in the expressed juice. It will be seen from the above summary that the present condition of the subject is very unsatisfactory, and that further experiments in nearly every direction are needed with pure materials and known organisms. Much of the past work has been done by chemists who have neglected the biological portion of the work, or biologists who have not noted the exact chemical changes which occur. Steps towards a better grasp of the subject are being made by several investigators. Experiments by Fitz, Marpmann, and more recently by Warrington and Percy Frankland, have given definite data for future work. These experiments were made with pure cultivations of known organisms, and the amount and quality of chemical change carefully determined. Recent work seems to indicate that bacteria and moulds,

living anaerobic, bring about most fermentations, and that, for these organisms to live, certain conditions are necessary, the most important of which is that their special nitrogenous pabulum is present. The way in which the enzymes or unorganised ferments act is still imperfectly understood. The decomposition effected by their agency is not so complete as in the other cases. Generally the change appears to be one of molecular rearrangement only, and no alteration in the distribution of energy takes place. Bacteria may, however, play an important part in the changes which are now attributed to these unorganised ferments, and they may, therefore, only be the means of educating some of the common bacteria into doing special work. All the unorganised ferments contain nitrogen, and it is certain that the bacteria cannot live without some nitrogenous substance being present. It is known that the same species of bacterium, by varying the conditions of life, is capable of giving very different chemical products. It may be that the unorganised ferments do not by themselves determine the change, but that bacteria are induced by them to work in special manners. When we consider the various food-stuffs which are resolved by the higher organisms into the same products, we see that the same organism is capable of a wide range of pabulum or can bring about a great number of chemical decompositions. Wortmann, on the other hand, is of opinion that bacteria effect fermentation by producing first an unorganised ferment which then brings about the changes which are ascribed to the bacteria. Yeast, for example, secretes an unorganised ferment, invertin, which has the property of resolving cane sugar into glucose. Starch is also converted into a sugar capable of reducing cupric oxide by bacteria in the absence of other sources of carbon nutriment, and this action is due to the secretion of a ferment by the bacteria. The ferment is soluble in water and precipitable by alcohol. It acts on starch in the absence of oxygen and is secreted by bacteria in a neutral starch solution. It does not possess any peptonising properties, but under different conditions the same bacteria can form (1) an amylolytic (diastatic) ferment, and (2) a peptonising ferment (Wortmann, *H.* 6, 287-329). Warington has shown that *Micrococcus gelatinosus*, *M. ureæ*, *B. fluorescens liquescens*, soil and Koch's cholera spirillum, curdle milk readily without producing any appreciable acidity. The curdling cannot be due to the formation of lactic acid, but points to the secretion of a rennet-like ferment by these organisms (Warington, *C. J.* 1888, 787). Stutzer has likewise found that moulds grown in a solution of salts and tartaric acid formed albumen and nuclein (*H.* 6, 572-574). Yeast, according to Hoppe-Seyler, also forms nuclein.

Fermentation processes may for our present purpose be conveniently classified according to the principal products formed.

*Ethyl alcohol* is formed from sugars, starch, and glycerin. *Propyl*, *Butyl*, *Amyl*, *Hexyl*, and *Heptyl* alcohols are all produced under suitable conditions. The formation of *mannite* and *gum* from sugar, and the ferment oils may also be included under the heading of alcoholic fermentation.

Fermentation resulting in the production of acid bodies includes the formation of *acetic acid* from alcohol, *butyric acid* from lactic acid, *lactic acid* from sugar, and *nitric* and *nitrous acids* from ammonia. *Ammonia* from urea and the *ptomaines* from albumen are examples of basic fermentation.

The enzymes as we have seen do not form such simple products as are produced when the fermentation is the result of the action of bacteria and moulds. They may be classified into: 1. *Sugar-forming*, including diastase, ptyalin, myrosin, emulsin, invertin, and the ferment of the pancreas. 2. *Peptone-forming*, including pepsin, papain, and trypsin. 3. *Albumen-forming*, the more important of which are the ferments of the liver and blood and chymosin. 4. *Glycerine-forming* or fat-decomposing, of which the ferment of the pancreas and Frey's pectase are examples. 5. According to Musculus an unorganised ferment exists in urine and forms ammonia from urea (*Pf.* 12, 214). Mayer (*Lehre von den Chem. Fermenten*, 1882, 82-91) has examined the quantity of enzyme required to produce a given amount of decomposition, and has shown that the amount of fermentation varies directly with the amount of ferment employed. He has also established the fact that the enzyme is not destroyed by its own ferment action. The precise manner in which the chemical ferments act has been the subject of much speculation. Most of the facts can be explained on a theory of action similar to that of sulphuric acid in etherification, but a 'contact' theory seems more probable. If the enzymes by their presence raise the molecular temperatures of the decomposing molecules to the point at which their molecular equilibrium is destroyed, then decomposition is produced by rearrangement of energy and not by any increase or decrease of the amount present in the system.

1. *Alcoholic or Vinous fermentation*. Solutions containing glucose  $C_6H_{12}O_6$  in contact with the air at temperatures between  $20^{\circ}$ - $24^{\circ}C$ . become turbid, give off  $CO_2$ , and after some time have the whole of the sugar converted into alcohol. Glycerin, succinic acid, and the higher alcohols are at the same time produced. When the evolution of carbonic acid ceases the ferment or yeast (*Torula* or *Saccharomyces cerevisiae*) separates leaving the liquid clear. The separated yeast is capable of inducing fresh fermentation in further quantities of sugar solution. Cane-sugar and milk-sugar also undergo various fermentations, but they are first hydrolysed by the ferment or commercially in other ways. Other ferments induce the vinous fermentation of sugar, e.g. *erythrosyn* the madder ferment (Schunck, *J. pr.* 68, 222) besides fungi. Rees (*Bot. Untersuch. u. d. Alkoholgärungspilze*) gives the following list of fungi which initiate alcoholic fermentation:—*Saccharomyces cerevisiae*, *S. ellipsoideus*, *S. pastorianus*, *S. apiculatus*, *S. exiguus*, *S. albicans*, *Mycoderma* (rarely), *Mucor racemosus*, *M. circinelloides*, *M. spinosus*, *M. stolonifer*, *Exoascus alnidiorum* (Sadlebeck), *Torula* and *Eurothium aspergillus glaucus*.

The following fungi do not form alcohol when sown in sugar solutions:—*Saccharomyces glutinis*, *Mycoderma* (generally), *Exoascus pruni*,

*Dematium pullulans* and *Fumago*. The nomenclature of the fungi is continually being modified, and Hansen of Copenhagen has restricted the genus *Saccharomyces* to the three species, *cerevisia*, *ellipsoideus*, and *pastorianus*, as they are the only sprouting fungi which form ascospores. Chemically yeast consists of cellulose (35), protein (45), peptone (2), fat (5), ash (7), and extractive matter (4) (Nägeli and Low), and the various yeasts have approximately the same composition. Schützenberger (*C. R.* 78, 498) has found that yeast when boiled with water yields an extract containing phosphates, gum arabin, leucine, tyrosine, carmine, xanthine, guanine, hypoxanthine, sarcine, and a sweetish uncrystallisable syrup still containing nitrogen. According to Béchamp fresh yeast contains neither tyrosine nor leucine (*C. R.* 78, 645). Roy-Pailhade (*C. R.* 107, 43) has shown that an organic compound named philothion, having the property of hydrolysing sulphur in cold solutions, is formed in the life processes of yeast. Concentrated methyl alcohol readily extracts it from the yeast. Dumas had previously noticed the property which yeast has, of forming  $\text{SH}_2$  from  $\text{S}$ . Pure yeast is best prepared by allowing fermentation to take place in a sugar solution in which a quantity of alcohol varying from 5-8 p.c. has been added, and the temperature not allowed to exceed  $15^\circ\text{C}$ . Such yeast can be grown in a solution rich in albumen at about  $30^\circ\text{C}$ . without any bacteria appearing (Traube, *B.* 9, 183, 1239). Hansen has devised a commercial method for obtaining pure yeast (Salomon, *J. Soc. Arts*, 1888). (For the composition of yeast *v.* Belohoubek, *J.* 1875, 898; Schützenberger a. Destrem, *C. R.* 88, 287, 883; Rommier, *C. R.* 98, 1594.) Vinous fermentation only takes place in dilute solutions of sugar, and as an increase of yeast takes place in fermentation, the liquid in addition to sugar must contain the elements necessary to form cellulose and protoplasm (P, K, Mg, Ca, and S) and a nitrogenous food. Proteids or peptones are the best form for the nitrogen, but acetamide, methylamine, ethylamine, propylamine, asparagine, and leucine, are all assimilated by the yeast cells (Nägeli). Oxamide and urea supply nitrogen but not carbon, while cyanogen compounds yield up their carbon but not the nitrogen to these organisms. Formic and oxalic acids are also unsuitable for the carbon supply of these fungi. Yeast loses a considerable portion of its fermenting power by pressure, and still more by washing with water.

Glycerin also deprives yeast of its fermenting power (Gunning, *B.* 5, 821). The influence of the age of the yeast on fermentation has been studied by Regnard (*C. R. Soc. Biol.* [8] 4, 442). Maltose and glucose are the two sugars which are most readily fermentable by yeast. All the true *Saccharomyces* ferment maltose, but *S. exiguus* and *S. apiculatus* are unable to decompose this sugar. The more complex carbohydrates are sometimes hydrolysed or inverted before alcoholic fermentation takes place. The higher dextrins are hydrolysed into maltodextrin and subsequently split up into maltose and dextrin by *S. pastorianus* and *S. ellipsoideus*. *S. cerevisia* is unable to resolve maltodextrin into maltose and dextrin. The conversion of

cane-sugar into glucose is apparently brought about by a soluble ferment termed invertin, which is secreted within the cells of all true *saccharomyces* (Donath, *B.* 8, 795). This soluble ferment has been isolated in the form of a powder. It is not formed by *S. apiculatus* nor by four out of the five varieties of Pasteur's *Torula* (Hansen). *Monilia candida* ferments cane-sugar, but there is no invertin formed, the inversion being probably due to the secretion of some other soluble ferment. *Mucor racemosus* and *M. mucedo* both set up alcoholic fermentation in solutions of glucose. *M. racemosus* does not ferment inulin, but readily ferments the levulose prepared from it. The alcoholic fermentation due to *M. mucedo* takes place in the absence of oxygen at temperatures between  $25^\circ$ - $28^\circ\text{C}$ . Succinic acid but no glycerin is produced by this fungus (Fitz, *B.* 6, 48). Dextrin, inulin, and milk-sugar do not ferment under the influence of mucor.

The alcoholic fermentation of milk-sugar according to Blondot is brought about by a special alcoholic ferment which does not manifest any action below  $20^\circ$ , and then only when the liquid is agitated. A small quantity of butyl alcohol is at the same time produced. Vieth has also shown that yeast does not readily set up alcoholic fermentation in solutions of milk-sugar. Kefir grains, which contain a bacillus termed *Diospora caucasia* by Kern and a modified form of *S. cerevisia*, produce a rapid alcoholic and lactic fermentation in milk-sugar solutions (*Analyst*, 12, 2).

Ethyl alcohol is obtained from other substances by fermentation.

According to Fitz (*B.* 9, 1848; 10, 276; 11, 42) alcohol is produced when schizomycetes are added to a solution of glycerin, mannite, starch, dextrin, milk-sugar, or dextrose, but, as the fermentation only takes place in the presence of some nitrogenous material, pepsin or ammonium sulphate is added to the solution. Acids are at the same time produced, *n*-butyric acid being the one most frequently formed. Quercite yields no alcohol and only *n*-butyric acid.

The quantities of the products formed in alcoholic fermentation vary with many conditions which have not yet been fully determined. Glycerin, succinic acid, and traces of high alcohols are almost always produced. An analysis of the products obtained by the fermentation of 100 kilos. of sugar by *S. ellipsoideus* gives the following numbers in grams:

Ethyl alcohol 50615.0, *n*-propyl alcohol 2.0, isobutyl alcohol 1.5, amyl alcohol 51.0, ethyl heptate 158.0, glycerin 2120.0, acetic acid 205.3, succinic acid 452.0, and traces of aldehyde. Small quantities of bases appear likewise to be produced, and *n*-butyl alcohol and butyric acid are frequently formed. An examination of the products of the fermentation of sugar solutions by different yeasts has been made by Claudon a. Morin (*Bl.* 42, 178-189). Lindet (*C. R.* 107, 182) has shown by experimenting with the same yeast on the same wort that the amount of higher alcohols produced varies with the temperature. The maximum amount of ethyl alcohol is produced at the same temperature ( $8^\circ$ - $10^\circ\text{C}$ ) as that when the amount of

higher alcohols is a minimum (.52 p.c.). At the temperature 25°-27°C. .59 p.c. of the higher alcohols was produced.

Formation of the higher alcohols by fermentation.—Fitz (B. 13, 36, 1811) has shown that the schizomycetes form *n*-propyl alcohol from glycerin. It is also a constituent of most fusel oils.

*n*-Butyl alcohol has been obtained by the same observer by the action of a bacillus allied to, but somewhat larger than *B. subtilis*, on glycerin in the presence of  $\text{CaCO}_3$  (B. 11, 42, 1892; 9, 1348). Vigna (B. 16, 1438) has suggested this formation of *n*-butyl alcohol as a method of its preparation, since the yield is 9 p.c. of the glycerin used.

*Iso-butyl alcohol* has been found in the fusel oil from mangolds (Wurtz, A. Ch. [3] 42, 129).

*Isoamyl alcohol* is the principal constituent of the fusel oil formed in the ordinary fermentation of potatoes. Pierre (J. 1871, 832) has shown that the higher the temperature of fermentation the greater the quantity of this alcohol. An active and an inactive amyl alcohol have been separated from fusel oil. *Iso-butyl* and traces of other alcohols are also formed (Perrot, A. 105, 64). In Swedish fusel oil Rabuteau has found *propyl*, *iso-propyl*, *iso-butyl*, *iso-amyl alcohols*, *methyl propyl carbinol* and liquids boiling above 132° (Bl. 33, 178) (v. Wyschnegradsky, A. 190, 365).

*n*-Hexyl and *n*-heptyl alcohols also occur in fusel oils (Faget, A. 88, 325; J. 1862, 412).

Lebel has shown that *Penicillium glaucum* acts upon the methyl-propyl-carbinol obtained by the reduction of methyl propyl ketone, yielding an alcohol which has a levorotation of  $-12^\circ$  (Lebel, J. 1879, 492).

*Mannite and gum*, under certain conditions, are formed from cane-sugar. Pasteur (Bl. 1861, 30) pointed out that when this *mucous fermentation* takes place in solutions of cane-sugar,  $\text{CO}_2$ , mannite, and a mucilaginous substance are produced. Access of air and nitrogenous matter are necessary for this fermentation. Neither acid nor alcohol is produced, and the fermentation only takes place in neutral or slightly alkaline solutions (Bauer, B. C. 1882, 630). This kind of fermentation has been noticed in solutions of cane-sugar, beet juice, carrot juice, the juice of mangold wurzel, and in lemonade. Baudrimont (C. R. 80, 1253) observed the occurrence of a spontaneous viscous fermentation in a solution of crystallised cane-sugar (v. Hochstetter, J. pr. 29, 80; Kircher, A. Ch. 31, 337; Plagne, J. Ph. 26, 248; Commaille, M. Sci. 3, 435, 678, 773).

A white substance resembling cellulose is formed under certain conditions in beet juice and beet molasses. It is precipitated from the solution by the addition of alcohol. Certain fatty seeds (rape, colza, &c.) form cellulose from saccharose (Durin, C. R. 82, 1078; Pasteur, C. R. 83, 176). For the fermentation of cellulose itself v. Tappeiner & Z. B. 24, 105; Hoppe-Seyler, B. 16, 122; Popoff, Pf. 10, 113.

Lecanartier and Bellamy have shown that certain fruits and roots under the influence of oxygen become the seat of an alcoholic fermentation characterised by the evolution of carbonic acid and the disappearance of sugar in the

tissues of the plant cells. From these and other experiments Pasteur considered that if plants could continue to live in an atmosphere of carbonic acid they would become fermenters for sugar. Mants (C. R. 86, 49), on examining this intracellular alcoholic fermentation of plants, has arrived at the following results:—1. That plants preserved in air give no trace of alcohol. 2. That plants placed in an atmosphere of nitrogen form appreciable quantities of alcohol, sometimes amounting to 1,000 times the total weight of the plants. 3. That the plants when returned to the air remained perfectly healthy. The living cell, then, in the higher plants is capable, in the absence of oxygen, of acting like the cells of fungi in producing a true alcoholic fermentation. The volatile oils, which are produced by the fermentation of various plants, may owe their origin to some such similar action of the living cells of the plant in the absence of oxygen. They are known as *FERMENT OILS*, and are formed when portions of the plant are left to ferment in water, and can then be distilled from the liquid. The distillate is then saturated with common salt and extracted with ether. Little is known as to the constitution of these bodies. Berzelius regarded them as peculiar alcohols related to fusel oil (B. J. 27, 641). They have been examined by Bley, Landerer, Büchner, and others. The following is a list of the more important plants from which ferment oils have been obtained:—*Charophyllum sylvestre*, *Chelidonium majus*, *Conium maculatum*, *Erythraea centaureum*, *Echium vulgare*, *Erica vulgaris*, *Marrubium vulgare*, *Achillea Millefolium*, various species of *Plantago*, *Quercus robur*, *Salix pentandra*, *Salvia pratensis*, *Trifolium fibrinum*, *Tussilago farfara*, *Urtica urens*, and *Vitis vinifera*. A similar ferment oil is produced in cellulolastasis, a disease of the apple (Gm. 14, 413).

On alcoholic fermentation the reader may consult for further information—Amthor, H. 12, 64; Béchamp, C. R. 88, 719; Berthelot, C. R. 89, 806; Cochin, C. R. 89, 786; 89, 992; Giacosa, B. 12, 703; Hoppe-Seyler, B. 12, 702; Petit, C. R. 73, 267; Schützenberger, C. C. 1877, 73; Schützenberger & Destrem, C. R. 88, 593.

The formation of acids by fermentation. The conversion of alcohol into acetic acid seems to be a catalytic action, as platinum black and other finely-divided substances facilitate the transfer of the atmospheric oxygen besides the organisms which bring about the same change.

*Acetous fermentation* takes place in presence of a fungus *Mycoderma aceti*, vinegar plant or mother of vinegar, and a bacterium (*B. aceti*). Both these organisms are usually present, and apparently the bacterium completes the work of the mycoderma. It is believed that the function of mycoderma is to convert starch into alcohol, and that the alcohol produced in this or other ways forms the pabulum of the *B. aceti*, which causes the oxidation of the alcohol to acetic acid. K, Mg,  $\text{NH}_4$ , and  $\text{H}_2\text{PO}_4$  are necessary for the growth of mycoderma (Pasteur, J. 1861, 726; 1862, 475). The same organisms appear to be capable of completely oxidising the acetic acid which they form to carbonic acid and water, if it be not removed. This is especially the case if the growth be allowed to sink to the bottom

of the liquid. A temperature ranging from 20°–35° is the best for the change, and above 50° all fermentation ceases.

The formation of acetic acid at times accompanies alcoholic fermentation (Béchamp, *J.* 1863, 773; Blondeau, *C. R.* 57, 953; Pasteur, *Études sur la vinaigre*, Paris, 1868). Acetic acid is also produced, together with butyric acid, in the fermentation of a mixture of malt, milk, chalk, and rancid meat (Grillone). According to Béchamp (*C. R.* 76, 836) it is normally present in milk, together with alcohol, as a product of the action of microzymes.

Acetic acid and butyric acid are formed by the action of yeast, at a temperature of 20°–30°, on citric acid, to which excess of chalk has been added. Putrefying curd and a base effect the same change (How).

*Lactous fermentation* or the formation of lactic acid from the sugars—glucose, cane- and milk-sugar—takes place when these bodies are mixed with fresh sour cheese, or with milk and chalk. After some time the lactic acid is itself attacked, and  $H_2CO_3$  and butyric acid are produced. The lactic fermentation only takes place in a neutral or slightly alkaline solution. This condition is obtained by adding chalk or zinc white to the sugar solution. Traces of mannite are also formed (Fremy, *A.* 31, 188; Boutron, *A.* 39, 181; Bensch, *A.* 61, 174; Lautermann, *A.* 113, 242). The decomposition of the calcium lactate into butyric acid appears to be due to the action of a bacillus (Pasteur, *J.* 1862, 477). The schizomycetes resolve it into propionic acid (Fitz, *B.* 11, 1898; 12, 479; Strecker, *A.* 92, 80), acetic acid, and sometimes *n-valerianic acid* (Fitz, *B.* 13, 1309). The fermentation of calcium lactate by the butyric ferment of Pasteur yields butyric acid, propionic acid, *n-valerianic acid*, and some ethyl alcohol (Fitz, *B.* 13, 1310). The ordinary lactous ferment, according to Pasteur (*A. Ch.* [3] 52, 404), is *Penicillium glaucum*. It resembles beer yeast, and is grey in colour, and has been described by Pasteur and Blondeau. Free acid retards its action, nitrogenous matter favours it, desiccation or boiling with water weakens it. All the sugar can be converted into lactic acid if ammonium salts and phosphates be present. Lactous fermentation often accompanies vinous fermentation (Blondeau, *J. Ph.* [3] 12, 257). The change may be brought about by the presence of a special bacterium (*B. acidilactici*) which accompanies the growth of *P. glaucum*. The conditions of lactic fermentation have been examined by Richet (*C. R.* 88, 750; *C. J.* 36, 663) and Berthelot (*A. Ch.* [3] 55, 351).

*Butyric fermentation.*—We have seen that butyric acid is the final product in the lactous fermentation of sugar solutions. The conversion of lactic into butyric acid is accompanied by the evolution of hydrogen and carbonic acid, and butyl alcohol is also produced. The ferment, according to Pasteur, is a bacillus (*C. R.* 52, 844), which requires no oxygen for its life, and is not killed when carbonic acid is passed into the liquid. Ammonia and phosphates are necessary for the development of this fermentation (Pasteur, *Bl.* 1862, 52). Béchamp attributes the change to a ferment existing in the chalk which is added (*Bl.* [2] 6, 484), and Baudrimont to an

unorganised ferment (*C. R.* 80, 1253). Boehm (*B.* 8, 634) has observed that butyric fermentation accompanies the evolution of marsh-gas and ammonia, when plants are immersed in water free from air. Twigs of *Elaeagnus canadensis* immersed in sugar syrup set up a fermentation which gives butyric acid, butyric ether, carbonic acid, and hydrogen (Schützenberger, *C. R.* 80, 928, 497). According to Fitz (*B.* 9, 1348), glycerin saturated with calcium carbonate undergoes fermentation, yielding butyric acid, *n*-butyl alcohol, and traces of ethyl alcohol. Fibrin also forms ammonium butyrate by fermentation (Wurtz, *A.* 52, 291), and Fitz has found that pepsin and glycerin, in presence of chalk, is fermented by schizomycetes at 40° into *n*-butyl alcohol, *n*-butyric acid, besides traces of ethyl alcohol and a higher acid, probably hexoic (*B.* 9, 1348; 10, 276; 11, 42). Pribram (*J.* 1879, 614) has formed butyric acid by the action of the ferment of calves' liver on starch paste, and Fitz has found that *B. subtilis* ferments potato-starch containing salts into butyric acid and small quantities of alcohol, acetic and succinic acids (*B.* 11, 52). Other contributions to our knowledge of this kind of fermentation are by Iljenko, A. Laskowsky, *A.* 55, 85; Iljenko, *A.* 63, 268; Grillone, *A.* 165, 127.

*Gluconic acid* is produced by the fermentation of glucose solutions by *Mycoderma aceti* (Boutron, *C. R.* 91, 230). Maumené contends that this change is merely oxidation, as copper acetate and mercuric oxide give similar results (*C. R.* 91, 331).

*Nitrification.* The term given to the oxidation of ammonia to nitric and nitrous acids by an organism or organisms present in the soil. The formation of nitre in nature, and artificially in nitre beds, is due to the same cause. Many experiments have conclusively proved that the direct combination of oxygen and nitrogen does not take place to any large extent in nature, and even ozone appears to be incapable of oxidising nitrogen. Kuhlmann was the first to explain the presence of nitric acid and nitrates in the soil as due to the oxidation of ammonia. This theory is now held, but the oxidation is indirectly brought about by the action of organisms. The first suggestion that the oxidation of ammonia and organic nitrogen in the soil is the work of a living organism was made by Pasteur in 1862. Müller, in 1873, showed that the ammonia of sewage and of impure well waters changed spontaneously into nitric acid, whereas solutions of pure ammonium salts and urea remained unchanged. Schlosing and Mintz (*C. R.* 77, 203, 353; 84, 801; 85, 1018; 86, 982; 89, 1074) have established this hypothesis by experiment, and Warington (*C. J.* 33, 44; 35, 429; 45, 658; 51, 118), at Rothamsted, has shown that the nitrification in soil and in waters is due to an organised ferment. The organism is destroyed at 100°C., and by  $CHCl_3$ ,  $CS_2$ , and phenol. *Penicillium glaucum*, *Aspergillus niger*, *Mucor mucedo*, *M. racemosus*, *Mycoderma vini* and *M. aceti*, as well as the ordinary forms of bacteria present in the atmosphere, are all incapable of effecting nitrification. Schlosing and Mintz state that they have isolated the organism in minute round or slightly elongated corpuscles, which multiply by budding, and appears to be a

micrococcus. The fermentation takes place in presence of alkaline carbonates or calcium carbonate. Besides the humic matter of soil, tartaric acid, sugar, alcohol, glycerin, and albumen are effective as food for the growth of this organism. Light is not favourable to nitrification. The change commences slowly, gradually attains a maximum of energy, and then becomes slow again. The formation of nitrous acid by this organism is rare in the soil, but frequent in liquids. The influence of temperature, concentration of the solution, depth of liquid, proportion of organic carbon, and degree of aeration has been studied by Warington and the French observers. Warington (*C. J.* 1888, 727-755) has tested for nitrates in cultivations of upwards of twenty organisms with negative results. Hereus (*Zeit. f. Hygiene*, 1886, 193) has, however, succeeded in isolating two or three organisms which he states induce the formation of nitrite in urine and in mineral solutions containing ammonium salts. Percy Frankland has not succeeded in isolating the organism; Leone, on the other hand (*Atti d. R. Accademia d. Lincei*, 1887, 37), concludes from his experiments that all micro-organisms are more or less capable of producing nitric acid, and that the same organisms in the presence of organic matter are capable of reducing nitrates. Celli a. Zuco (*Gazz.* 17, 99), Frank (*Forsch. a. d. Gebiete d. Agriculturphysik*, 10, 56) and Adametz (*l. c.* 1886, 381) may also be consulted for further information on this subject.

#### Bases produced by Fermentation.

1. *Ammonia from Urea.*—The ammoniacal fermentation of urea which takes place in urinals is due to the action of a bacterium (*B. ureæ*). The urea is converted into ammonium carbonate, but the change only takes place when mucus or other organic substances are present, as urea dissolved in pure water remains unaltered. In presence of yeast the change takes place very quickly (Schmidt, *A.* 61, 168). According to Musculus (*B.* 9, 357) an enzyme is present in the urine of persons affected with catarrh of the bladder, which also brings about this change. It is precipitated by alcohol as a coagulum resembling fibrin, and decomposes urea completely into carbonic acid and ammonia at 35°-40°. It has also the power of decomposing hippuric and uric acids, creatine and guanidine. Its action ceases in the presence of dilute HCl and most other acids, but small quantities of phenol have no retarding action. Dilute alkalis and sodium chloride have no influence. More recently the presence of ferments in normal urine has been confirmed by Städelmann (*Z.* *B.* 24, 226, 260). He finds that pepsin is always present in normal urine, but in no instance has trypsin been discovered. This conclusion agrees with that arrived at by Leo and Hoffmann (*Fr.* 27, 123), and is contrary to the experiments of Grützner and his pupils Sahli, Gehrig, and Holovtshiner. Raw fibrin does disintegrate in alkaline urine, even in the presence of thymol, owing, no doubt, to bacteria in the fibrin; but in no instance did digestion or disintegration take place when boiled fibrin was used.

Warington has tested the ability of over twenty organisms to hydrolyse urea. A sterilised 25 p.c. solution of urine was employed. *Micrococcus (B.) ureæ* gave a considerable increase of alkali-

linity, and *B. fluorescens non-liquefescens* a somewhat smaller increase. Arable soil gave a much larger increase than either. The other organisms used had no effect ('The Chemical Actions of Some Micro-organisms,' Warington, *C. J.* 1888, 727-755).

2. *Ammonia from Nitrates and Nitrites.* *Partial reduction of Nitrates.*—Meusel (*A.* [5] 7, 297) observed that water containing nitric acid and carbohydrates, and originally free from nitrites and ammonia, contained the latter after being subjected to the action of bacteria; and that water, freshly distilled and mixed with sugar, was not found to reduce nitrates when the air was excluded from it. Percy F. Frankland has recently shown (*C. J.* 53, 373) that out of thirty-two different micro-organisms examined sixteen or seventeen have the power of reducing nitrates to nitrites more or less completely. The absence of air has no influence on the result. In many cases the change is a quantitative one. Ammonia was also sometimes formed; but it was due to the decomposition of the peptone, which was the only other nitrogenous ingredient present. *B. ramosus* and *B. pestifer* have very marked nitrate to nitrite reducing action. The yield of nitrite was augmented by increasing the amount of sugar and peptone present. *B. aquatilis* does not reduce nitrate to nitrite, but causes the disappearance of nitric nitrogen, the deficiency not being accounted for by the small quantity of ammonia which was generated in the solution. According to Warington, the organisms which appear to possess the greatest power of reducing nitrates to nitrites are *B. floccus*, *B. fluorescens non-liquefescens*, *B. of swine fever*, *M. ureæ*, *M. gelatinosus*, *Staph. cantidus*, and *Staph. luteus*. The following also reduce nitrates freely: *B. termo*, *B. of typhoid fever*, *B. of infantile diarrhoea*, *B. of cholera*, *B. of septicæmia*, *B. anthracis*, *B. Demcke's comma*, and *Staph. albus liquefescens*. *B. subtilis* yields no nitrite in a urine solution, but forms a trace of nitrite in broth after some time. *Streptococcus scarlatina* yields a mere trace of nitrite in broth cultures. *B. fluorescens liquefescens*, *B. toruliformis*, *B. sulphureus*, *B. Finkler's comma*, *B. comma noma* and *M. aureus*, failed entirely to effect reduction to nitrites (Warington, *C. J.* 1888, 727-755).

3. *Bases formed in fermentation.*—Poisonous bases having properties resembling the alkaloids are produced in putrid fermentation, and also in small quantities in alcoholic fermentation. The bases formed in the putrefaction of meat and fish are known as ptomaines, and a considerable amount of literature on their formation and properties now exists, which it is impossible to deal with in the present article. Gautier a. Etard (*C. R.* 94, 1598) have shown that the complex phenomena of putrid fermentation may be regarded as brought about by the hydration of the complex albuminoid molecules into simpler molecules. Two compounds are apparently first formed, one of which is stable and gives rise to the glucos-proteins and leucines, to which Schützenberger attributes the formula  $C_4H_7N_3O_8$ , while the other is unstable, and decomposes rapidly into  $NH_3$ ,  $CO_2$ , formic, acetic, and oxalic acids.

In Schützenberger's method of hydration with barium hydrate, the amides are not hy-

drated, but bacteria in putrefaction slowly change them into ammoniacal salts. The crystalline body  $C_8H_{11}N_3O$ , produced abundantly in the putrefaction of fish also undergoes hydration when similarly treated. Putrefaction being essentially a process of hydration it follows that the aromatic derivatives and the bases produced during fermentation pre-exist as nuclei in the flesh. The bases formed in the putrefaction of the skate can be obtained by acidulating the liquid products with sulphuric acid. On evaporation, *in vacuo*, indole, phenol, and other volatile products are removed and the residue, after treatment with baryta, is extracted with chloroform. The bases are colourless oily liquids and resemble those described by Selmi. They have an odour like that of the carbamines and hydrocollidine. By fractionation two bases,  $C_8H_{11}N$  and  $C_8H_9N$ , have been isolated. The latter (110°) closely resembles Cahours's and Etard's hydrocollidine, with which it is probably isomeric. Two bases having the formula  $C_8H_9NO_2$  and  $C_8H_9NO$ , have similarly been obtained from the products of the putrefaction of flesh and fibrin (Salkowski, B. 12, 648; 16, 1191). Brieger (B. 16, 1186) has extracted from putrefied horseflesh the bases  $C_8H_9N_2$  and  $C_8H_9N$ . A base having the formula  $C_8H_{10}N_2$  (171°) and soluble in most solvents has been isolated by Morin from the products of alcoholic fermentation. It forms a double Pt salt and gives precipitates with the usual alkaloid reagents (C. R. 106, 360). Its toxic effects have been studied by R. Wurtz (C. R. 106, 363). Tanret considers this base identical with ( $\beta$ )-glucosine obtained from glucose and ammonia (C. R. 106, 418). An examination of the amount of nitrogen bases present in fermented liquids (brandy, rum, &c.), has also been made by Lindet (C. R. 106, 280).

**Sugar-forming ferments.**—The more important chemical ferments which belong to this group are diastase, ptyalin, myrosin, emulsin, invertin, animal invertin, and one of the ferments which exist in the pancreas. They are found in the animal and vegetable kingdoms, in the former they are secreted by some of the principal organs, in the latter they occur in various parts of the plant. The sugar produced may be either dextrose or maltose, and the substance decomposed differs with the different ferments, starch, cane-sugar, and the various glucosides being the more important; we have already seen that the enzymes may be isolated by precipitating the aqueous extracts of the organs containing them with alcohol. They are also mostly soluble in glycerin, which may be used to extract them from the finely divided material. The glycerin extract is then dropped slowly into strong alcohol, and the precipitated ferment collected. The chemical composition of these bodies has been investigated by Krauch, Dubrunfaut, Hüfner, Donath, Barth, and others, and from their analyses it is known that they all contain a considerable percentage of nitrogen. Invertin, emulsin, and the diastatic pancreas ferment also contain sulphur. The influence of temperature and light upon their action has already been alluded to. Dried diastase can be heated to 158°, and the pancreatic ferment to 162°, without destroying their fermentative property. The amount of work which they are able to perform

in a given time is, however, diminished by heating above 100° (F. Hüppe, C. C. 1881, 746). Chloroform, carbon bisulphide, ether, prussic acid, do not retard the action of these ferments, but most acids and alkalis hinder their action. All salts and bodies which coagulate albumen have the property of stopping this kind of fermentation. The chemical change brought about by the sugar-forming enzymes is one of hydrolysis. Diastase, ptyalin, and the diastatic pancreas ferment convert starch or glycogen into a sugar (maltose) and dextrin. The pancreatic ferment and ptyalin yield a dextrin (achroodextrin) which differs from the dextrin obtained by means of diastase in not reacting with iodine (Naffe, Pj. 14, 473). Invertin converts cane-sugar by hydrolysis into dextrose and levulose. The ferment action of emulsin consists in the hydrolysis of the glucosides. Glucose is the constant product of the action. The following are those decompositions which are best established. Salicin to saligenin, helicin to salicylic aldehyde, arbutin to hydroquinone and methylhydroquinone, amygdalin to benzoic aldehyde and prussic acid, coniferin to coniferyl alcohol and daphnin and convolvulin are similarly hydrolysed by emulsin. Nencki is of opinion that in hydrolysis the water is split into hydrogen and hydroxyl by emulsin (J. pr. 17, 103). Myrosin appears to determine the breaking up of the molecule of potassium myronate or of the free myronic acid into mustard oil, sugar, and sulphate without the assimilation of the elements of water. It seems probable that with further investigation the formula of myronic acid may be modified and that this ferment change will also be found to be one of hydrolysis (Will a. Körner, A. 125, 263; Franchimont's Kort Leerboek).

**Peptone-forming ferments. Digestion.**—The peptone-producing ferments, pepsin, trypsin, pepsin (of plants), and papain, convert albumen into peptone. This change apparently is brought about in a similar manner to those of the last-mentioned group, the elements of water being taken up by the albuminoid substances. Other bodies besides peptone are produced, trypsin and papain yielding crystalline amido-compounds (leucine). Wurtz is of opinion that papain acts by combining first with the fibrin, and that an insoluble product is thereby produced, which by the action of water is reconverted into the ferment and soluble substances resulting from the hydration of the fibrin (Wurtz, C. R. 91, 787; 93, 1104). Pepsin also seems to first form an insoluble compound with fibrin, which is subsequently broken up by water. Certain bacteria resemble these enzymes in their action, and probably have this property from secreting a similar ferment. The principal albumen-forming ferments are the liver ferment, the blood ferment, and chymosin. Ferments analogous to the liver ferment exist in the vegetable kingdom. The conversion of casein into cheese by rennet is an example of this class of fermentation, and from the analyses of these two bodies it seems probable that in this case also the change is one of hydrolysis. A ferment similar to that existing in the liver is found in certain plants, notably in *Oxalis Acetosella*, *O. stricta*, *Cirsium arvense*, *Rumex Patens*, in the leaves of artichokes, and

in the seeds of black pepper and *Wilhamia coagulans*. Certain bacteria separate a ferment which behaves like chymosin.

A ferment also exists in the pancreas, which is capable of decomposing the fats into glycerin. Not only are the triglycerides attacked, but complex molecules like lecithin are also hydrolysed.

**Antiferments or Antiseptics.**—Many inorganic and organic substances have the property of arresting or hindering fermentation. They act by killing the organisms which bring about the fermentation, and most of the substances which have poisonous properties have also antiseptic properties. In the earlier experiments it was noticed that while creosote and phenol arrested the development of fungi and germs fermentation still proceeded, and Buchholz (*J.* 1867, 742) found that milk turned sour when phenol was present. Naunyn (*J.* 1865, 606) noted that benzene interfered with the action of yeast on sugar solutions. Pienkowsky (*J.* 1865, 606) examined the antiseptic action of a considerable number of salts on meat with the following results:—

No antiseptic action:

Alum,  $\text{Al}_2\text{SO}_4$ ,  $\text{Na}_2\text{HPO}_4$ ,  $\text{Sr}_2\text{NO}_3$ ,  $\text{Ba}_2\text{NO}_3$ ,  $(\text{NH}_4)_2\text{C}_2\text{O}_4$ ,  $\text{Na}_2\text{C}_2\text{O}_4$ ,  $\text{BaCl}_2$ ,  $\text{Na}_2\text{SO}_4$ ,  $\text{Na}_2\text{S}_2\text{O}_3$ ,  $\text{NH}_4\text{NO}_3$ ,  $\text{KClO}_4$ ,  $\text{Na}_2\text{SO}_4$ ,  $\text{K}_2\text{SO}_4$ ,  $\text{MgSO}_4$ ,  $(\text{NH}_4)_2\text{SO}_4$ ,  $\text{Mn}(\text{AcO})_2$ , and  $\text{As}_2\text{O}_3$ .

Delayed putrefaction for one month:

$\text{KAcO}$ ,  $\text{NaAcO}$ ,  $\text{Ca}(\text{AcO})_2$ ,  $\text{NaCl}$ ,  $\text{NH}_4\text{Cl}$ ,  $\text{SnCl}_4$ ,  $\text{MnCl}_2$ ,  $\text{ZnCl}_2$ ,  $\text{ZnSO}_4$ ,  $\text{FeSO}_4$ ,  $\text{K}_2\text{SO}_4$ , and  $\text{Pb}_2\text{NO}_3$ .

Delayed putrefaction for more than six months:

$\text{NH}_4\text{AcO}$ ,  $\text{Ba}(\text{AcO})_2$ ,  $\text{CaCl}_2$ ,  $\text{CuCl}_2$ ,  $\text{HgCl}_2$ ,  $\text{CuSO}_4$ ,  $\text{Pb}(\text{AcO})_2$ ,  $\text{K}_2\text{Cr}_2\text{O}_7$ , aniline nitrate, phenol, and acetic acid.

Formic acid, according to the same investigator, is a powerful antiseptic for sugar solutions. Severi (*Z.* [2] 4, 285) has examined the antiseptic action of the animal secretions. Alcoholic fermentation and putrefaction are arrested by gastric juice, but not by pepsin. Lactous fermentation is not retarded by either reagent.

Boric acid and most of its compounds have antiseptic properties. Dumas found that borax prevents the action of yeast water on sugar, of synaptose on amygdalin, and of myrosin or myronie acid. Calcium borate and boric acid either alone or mixed with glycerin prevent the formation of mildew and the putrefaction of meat. Mercuric oxide appears to be the most powerful of all antiseptics, and next to it mercuric chloride.

Among organic bodies phenol, chloral hydrate, chloroform, salicylic acid, benzoic acid, hydrocyanic acid, and thymol, all have marked antiseptic properties.

Of the alkaloids, quinine prevents, while nicotine accelerates fermentation. Calvert (*Pr.* 20, 191) found that on the addition of one thousandth part of the following antiseptics to a solution of albumen he obtained the following results:—

1. Phenol and creosol prevented the growth of fungi and bacteria.

2.  $\text{ZnCl}_2$ ,  $\text{HgCl}_2$ , and zinc phenol sulphonate prevented the development of vibrios, but did not stop the production of fungi.

3.  $\text{CaO}$ , quinine sulphate, pepper, and  $\text{HCN}$ , permitted the growth of vibrios, but allowed the fungi to develop.

4. Those which had no preventive action (under these conditions).  $\text{SO}_2$ ,  $\text{H}_2\text{SO}_4$ ,  $\text{HNO}_3$ ,  $\text{As}_2\text{O}_3$ ,  $\text{AcOH}$ ,  $\text{KHO}$ ,  $\text{NaHO}$ ,  $\text{NH}_3$ ,  $\text{Cl}$ ,  $\text{NaCl}$ ,  $\text{CaCl}_2$ ,  $\text{AlCl}_3$ ,  $\text{Ca}(\text{OCl})\text{Cl}$ ,  $\text{KClO}_3$ ,  $\text{CaSO}_4$ ,  $\text{FeSO}_4$ ,  $\text{CaSO}_3$ ,  $\text{Na}_2\text{S}_2\text{O}_3$ ,  $\text{Na}_2\text{HPO}_4$ ,  $\text{Ca}_2\text{PO}_4$ ,  $\text{KMnO}_4$ ,  $\text{K}$  and  $\text{Na}$ . Phenol sulphonates, picric acid, turpentine, and wood charcoal. Sodium silicate (Rabuteau & Papillon, *C. R.* 75, 755) prevents the alcoholic fermentation of grape-sugar, and the fluosilicates have also considerable antiseptic properties.

Salts of bismuth even in small quantities completely prevent secondary fermentations in worts (Gayon & Dupetit, *C. R.* 103, 883–885). The influence of calomel on fermentation and the life of micro-organisms has been carefully studied by Wassilieff (*H. B.* 112–134). The comparative antiseptic properties of  $\text{HgO}_2$ , mercuric oxyanide, and  $\text{HgCl}_2$ , have been determined by Chibret (*C. R.* 107, 119). Ratimoff (*J. Ph.* [5] 11, 83–90) has determined the limits between which lie the minimum quantities of various antiseptics required to kill and to prevent the development of microbes and bacteria in certain media.

The relation of antiseptic power to chemical constitution has been investigated by J. R. Dugan (*Am. J.* 62–64) by noting the amount of substance required to prevent fermentation by *Bacillus subtilis* in a solution of beef peptones. The following numbers show the relative antiseptic values of the materials used: Salicylic acid, 4; *m*-oxy-benzoic acid, 6; *p*-oxy-benzoic acid, 8; phenol, 20; pyro-catechol, 20; resorcin (25); hydroquinone, 30; pyrogallol, 15; methyl alcohol, 300; ethyl alcohol, 500; normal propyl alcohol, 200. Of the three phenol sulphonic acids the ortho-acid only has antiseptic and disinfecting properties in a marked degree (Vigier, *J. Ph.* [5] 11, 145–152, 214–217). Phloroglucin is possessed of no antiseptic properties, whereas pyrogallol is poisonous, and resorcin coagulates both vegetable and animal albumen (Andeer, *C. C.* 1894, 340–341). A paper by G. Marpmann (*Ar. Ph.* [3] 20, 905–924) deals with the methods for determining the vitality of those bacteria which cease to move when dead, and points out the difference between antiseptics and disinfection, and gives a list of the literature on the subject to 1881.

S. R.

**FERRATES.** Salts of the hypothetical ferri acid  $\text{H}_2\text{FeO}_4$ . Neither the acid nor its anhydrid ( $\text{FeO}_3$ ) has been isolated.

Stahl noticed in 1702 that a violet solution obtained by fusing iron with saltpetre and washing with water, or by adding a solution of iron in  $\text{HNO}_3$  to conc.  $\text{KOH}$ aq.

From measurements of the O evolved and the  $\text{Fe}_2\text{O}_3$  formed in the decomposition of K ferrate, Fremy gave the formula  $\text{FeO}_4$  to the hypothetical acidic radicle of the ferrates; this was confirmed by H. Rose, who determined the quantity of I set free from KI by reaction with Ba ferrate (A. 48, 230).

The ferrates have been examined by Fremy (C. R. 12, 23; 14, 442; 15, 1108; 16, 187); H. Rose (A. 48, 230; P. 59, 315); Denham Smith, (P. M. [3] 23, 217); Merz (J. pr. 101, 289); Poggendorff (P. 54, 373).

Barium ferrate,  $\text{BaFeO}_4 \cdot \text{H}_2\text{O}$ , has been obtained as a solid. The compositions of the soluble K and Na ferrates were deduced from estimations of the ratio of Fe ppd. as  $\text{Fe}_2\text{O}_3$  to O evolved by decomposing the solution by heat (Fremy, Denham Smith), and also by reducing by  $\text{SO}_2$ , and then estimating the ratio of  $\text{Fe}_2\text{O}_3$  ppd. to  $\text{SO}_2$  in solution (H. Rose).

Barium ferrate  $\text{BaFeO}_4 \cdot \text{H}_2\text{O}$ . Obtained as a purple-red powder by adding  $\text{BaCl}_2\text{Aq}$  or  $\text{Ba}(\text{NO}_3)_2\text{Aq}$  to  $\text{K}_2\text{FeO}_4\text{Aq}$ , washing, and drying (Denham Smith). It is more stable than  $\text{K}_2\text{FeO}_4$ ; decomposed by  $\text{HNO}_3\text{Aq}$ , slowly by  $\text{H}_2\text{SO}_4\text{Aq}$ ; sol. in acetic acid, forming a red liquid, which evolves O on heating; scarcely decomposed by organic salts.

Potassium ferrate,  $\text{K}_2\text{FeO}_4$ . Prepared by heating 2 pts.  $\text{KNO}_3$  in a large Hessian crucible, arranged so that only the bottom is heated to dull redness, and throwing in 1 pt. iron filings; the fused mass is extracted with cold water in a closed vessel (Fremy). More conveniently prepared by passing a rapid stream of Cl into conc.  $\text{KOH Aq}$  warmed to about  $40^\circ$ , holding  $\text{FeO}_3\text{H}_2$  in suspension; Merz (Lc.) recommends to dissolve 5 pts.  $\text{KOH}$  in 8 pts.  $\text{H}_2\text{O}$ , and to add 8 pts.  $\text{FeCl}_3\text{Aq}$  of S.G. 1.109; excess of Cl must be avoided. According to Fremy, crystals of  $\text{K}_2\text{FeO}_4$  may be obtained by making the  $\text{KOH Aq}$  very conc., and adding  $\text{KOH}$  from time to time as the Cl is passed in; the crystals may be freed from  $\text{KCl}$  by solution in water and ppn. by potash, they may then be dried on a porous tile and kept in sealed tubes. Poggendorff (Lc.) says that crystals of potassium ferrate may be obtained by an electrolytic method; a cylindrical vessel of porous porcelain is placed in a beaker cooled by ice; potash solution is poured into both vessels, a Pt plate, which serves as negative electrode, is immersed in the porous cylinder, and the positive electrode is a plate of wrought iron (not steel) which is placed in the beaker; when a strong current is passed, the liquid round the positive pole becomes dark red, and crystals of K ferrate form on the iron plate. Bloxam (C. N. 54, 43) says that a solution of  $\text{K}_2\text{FeO}_4$  may be obtained by adding a fragment of  $\text{KOH}$  to a little  $\text{FeCl}_3$ , and then a few drops of  $\text{Br}_2$ , heating gently and dissolving in water.

A conc. solution of  $\text{K}_2\text{FeO}_4$  is deep red; it is stable especially if a little  $\text{KOH}$  be present; on dilution and warming,  $\text{FeO}_3\text{H}_2$  is ppd., and O is evolved; the solution is decomposed by acids; it reacts towards  $\text{SO}_2\text{Aq}$ , &c., as an oxidiser; the solution is decolourised by metals and many salts of earth-metals, e.g.  $\text{Alum}$ ; it is also decolourised by  $\text{NH}_4\text{Aq}$  with evolution of N; the solution acts as an oxidiser towards most organic compounds which are oxidised by

$\text{KMnO}_4\text{Aq}$ , e.g. alcohol, sugar, albumen, potassium tartrate and oxalate.

Sodium ferrate  $\text{Na}_2\text{FeO}_4$ . Solution obtained similarly to  $\text{K}_2\text{FeO}_4\text{Aq}$ .

M. M. P. M.

#### FERRIC COMPOUNDS v. Iron.

##### FERRICYANIDES and FERROCYANIDES.

Salts of ferriocyanhydric acid  $\text{H}_3\text{FeCy}_6$ , and ferrocyanhydric acid  $\text{H}_4\text{FeCy}_6$ , v. pp. 333, 337.

FERRITES. Ferric oxide  $\text{Fe}_2\text{O}_3$  forms compounds with several metallic oxides more basic than itself; these compounds belong to the form  $\text{Fe}_2\text{O}_3 \cdot \text{M}_2\text{O}$  and  $\text{Fe}_2\text{O}_3 \cdot \text{MO}$ , where  $\text{M}_2 = \text{K}_2$  and  $\text{Na}_2$ , and  $\text{M} = \text{Ba}$ ,  $\text{Ca}$ ,  $\text{Cu}$ ,  $\text{Mg}$ , or  $\text{Zn}$ ; they are analogous in composition to the aluminates (q. v. vol. i. p. 141), and may be regarded as metallic derivatives of the hydroxide  $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O} (= \text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O})$ .

Barium ferrite  $\text{BaO} \cdot \text{Fe}_2\text{O}_3 = \text{BaFe}_2\text{O}_5$ . Obtained by List (B. 11, 1512), by pp.  $\text{FeCl}_3\text{Aq}$  by  $\text{BaO Aq}$ , as a brown, magnetic solid.

Calcium ferrite  $\text{CaO} \cdot \text{Fe}_2\text{O}_3 = \text{CaFe}_2\text{O}_5$ . Percy (P. M. [4] 45, 455) obtained this salt in metallic lustrous crystals, S.G. 4.693, by heating equal parts of  $\text{CaCO}_3$  and  $\text{Fe}_2\text{O}_3$  to white heat for several hours. List (B. 11, 1512) obtained the compound as a brown solid by adding  $\text{CaO Aq}$  to  $\text{FeCl}_3\text{Aq}$ , washing with  $\text{CaO Aq}$ , and heating (v. also Pelouze, A. Ch. [3] 33, 5; also Rousseau a. Bernheim, C. R. 106, 1726).

Copper ferrite  $\text{CuO} \cdot \text{Fe}_2\text{O}_3 = \text{CuFe}_2\text{O}_5$ . A brownish-black, magnetic solid; by adding  $\text{KOH Aq}$  to a mixture of  $\text{CuSO}_4$  and  $\text{FeCl}_3$  in quantity sufficient to ppt. all Cu, drying over  $\text{H}_2\text{SO}_4$ , in *vacuo*, and heating (List, Lc.).

Magnesium ferrite  $\text{MgO} \cdot \text{Fe}_2\text{O}_3 = \text{MgFe}_2\text{O}_5$ . Occurs native as *Magnetoferrite*. Obtained by mixing equivalent quantities of  $\text{MgSO}_4$  and  $\text{NaOH}$  and adding  $\text{FeCl}_3\text{Aq}$  until the liquid is still slightly alkaline, and heating the pp. strongly (List, Lc.). Krant (C. C. 1864. 1088) obtained  $\text{Fe}_2\text{O}_3 \cdot 6\text{MgO} \cdot 9\text{H}_2\text{O}$  by adding 6 equivs.  $\text{MgSO}_4$  and 1 equiv. of a ferrous salt to excess of  $\text{KOH Aq}$ , S.G. 1.1, boiling for some hours until the pp. was white, and drying at  $120^\circ$ .

##### Potassium and Sodium ferrites

$\text{K}_2\text{O}(\text{Na}_2\text{O}) \cdot \text{Fe}_2\text{O}_3 = \text{K}_2(\text{Na})_2\text{Fe}_2\text{O}_5$ . Formed by adding  $\text{Fe}_2\text{O}_3$  to molten  $\text{K}_2\text{CO}_3$  or  $\text{Na}_2\text{CO}_3$  (v. v. Schaffgotsch, A. Ch. 43, 17; Schneider, J. pr. 108, 19; List, B. 11, 1512). Rousseau a. Bernheim (C. R. 107, 240) describe  $\text{K}_2\text{O} \cdot \text{Fe}_2\text{O}_3$  as transparent, red-brown crystals; obtained by mixing crude K ferrite (best that made by fusing  $\text{FeO}_3\text{H}_2$  with 4 parts  $\text{K}_2\text{CO}_3$ ) with twice its weight of  $\text{KCl}$ , and heating strongly until most of the  $\text{KCl}$  is volatilised. Other crystalline compounds of  $\text{Fe}_2\text{O}_3$  with  $\text{K}_2\text{O}$  and  $\text{Na}_2\text{O}$  were obtained by heating  $\text{FeSO}_4$  with an equal weight of  $\text{KCl}$ .

Zinc ferrite  $\text{ZnO} \cdot \text{Fe}_2\text{O}_3 = \text{ZnFe}_2\text{O}_5$ . Occurs native as *Franklinite*. Obtained as minute, black, octahedral crystals, which are slightly magnetic, by heating to whiteness for 4 days a mixture of 1 pt.  $\text{Fe}_2\text{O}_3$ , 2 pts.  $\text{ZnO}$ , and 3 pts. fused  $\text{H}_2\text{BO}_3$ , and heating with dilute  $\text{HCl Aq}$ . S.G. 5.152 (Ebelmen, A. Ch. [8] 83, 47; v. also Daubrée, C. R. 89, 153; Reich, J. pr. 88, 266; and List, B. 11, 1512).

Ferrites of lead, manganese, and silver seem also to exist (v. List, Lc.; H. Rose, P. 101, 333; Fischer, S. 56, 361).

M. M. F. M.

xx 2

**FERULIC ACID**  $C_{10}H_8O_4$ , i.e.  $[C_6H_4(OMe)(OH).CH:CH.CO_2H]$ . Mol. w. 192. Occurs in *assafoetida*, from which it is freed by ppg. the alcoholic tincture with lead and decomposing the resulting lead salt (SO, (Hlasiwetz, A. Barth, A. 188, 64). Obs. also by boiling its acetyl derivative with conc. KOH. Long trimetric four-sided needles in boiling water). V. sl. sol. cold water, v. cold alcohol, m. sol. ether. Its aqueous solution is pptd. by  $Pb(OAc)_2$  and by  $Fe_2Cl_6$ ; noniacid  $AgNO_3$  gives an egg-yellow ppt.; action takes place on boiling. Potash-fusion is protocatechuic and acetic acids. It reduces boiling Fehling's solution. Sodium-alginate reduces it to hydroferulic acid  $I_2(OMe)(OH).CH_2CH_2.CO_2H$  [90]. Salts.— $NH_4^+Ag^+$ : laminae.— $KA^+$  (at 110°); aw-yellow deliquescent crystals.— $AgA^+$ .

**Acetyl derivative**  $H_4(OMe)(OAc).CH:CH.CO_2H$  [197°]. Prepared by boiling a mixture of acetyl-vanillin (pts.),  $NaOAc$  (5 pts.) and  $Ac_2O$  (15 pts.) for hours (Tiemann, A. Nagai, B. 11, 650). Vanillin may be used instead of its acetyl derivative. Tender needles, v. sol. alcohol and ether, sl. sol. ether.

**iso-ferulic acid**  $C_{10}H_8O_4$ , i.e.  $[3:1] C_6H_4(OMe)(OH).CH:CH.CO_2H$ . *Hesperic acid*. [228°].

**Formation**.—1. By the action of  $MeI$  and  $OH$  on caffeic acid (Tiemann, A. Nagai, B. 1, 654).—2. Together with phloroglucin by boiling hesperetin with dilute  $NaOH$ .

**Properties**.—White needles or plates. Sol. alcohol, ether, and hot water, sl. sol. cold water, benzene, and chloroform, insol. ligroin.

**Reactions**.—1. Fused with  $KOH$  it gives protocatechuic acid.—2. By reduction it gives hydro-isoferulic acid [146°]. On heating it gives  $CO_2$  and hesperetin  $[C_6H_4(OMe)(OH).CH:CH.]$ .

**Salts**.— $A^+Ca^{2+}$ : sparingly soluble needles. — $A^+Ag^+$ : slightly sol. pp. The salts of barium, zinc, copper, and lead are also sparingly soluble pps.

**Methyl ether**  $A^+Me$ . [79°]. Colourless needles. Soluble in alcohol.

**Acetyl derivative**  $C_6H_4(OMe)(OAc).CH:CH.CO_2H$  [199°]. Colourless plates. Soluble in alcohol and ether, insoluble in water. On oxidation with  $KMnO_4$  it gives isovanillic acid.

**Methyl-isoferulic acid**  $C_6H_4(OMe).CH:CH.CO_2H$ . V. Vol. i. p. 659 (Tiemann & Will, B. 14, 955).

**FERULIC ALDEHYDE**  $C_{10}H_8O_3$ , i.e.  $[3:1] C_6H_4(OMe)(OH).CH:CH.CHO$  [84°]. From its glucoside by treatment with emulsin at 35° (Tiemann, B. 18, 3484). Yellow needles. Sl. sol. cold water, v. sol. alcohol, ether, and benzene; insol. ligroin. Combines with  $NaHSO_3$ . Its aqueous solution is coloured green by  $FeCl_3$ , and on boiling with  $FeCl_3$  gives off an odour of vanilla.

**Glucoside**  $C_{16}H_{22}O_{10}$ , i.e.  $C_6H_4(OMe)(O.C_6H_4O_2).CH:CH.CHO$ . [202°]. From the glucoside of vanillin by treatment with aqueous  $NaOH$  and aldehyde (T.). Yellow needles (containing 2aq) (from water). Sl. sol. cold water, v. sol. alcohol, insol. ether, chloroform, and benzene. Laboratory.

**Oxim of the glucoside**  $C_6H_4(OMe)(OC_6H_4O_2).CH:CH.CH:NOH$ . [163°]. Needles, sl. sol. cold water, m. sol. alcohol, insol. ether.

**Phenyl hydrazide of the glucoside**  $C_6H_4(OMe)(OC_6H_4O_2).CH:CH.CH:N.NHPh$ . [213°]. Amorphous, v. sol. alcohol, v. sl. sol. water and ether.

**FIBRIN v. PROTEIDS AND BLOOD.**

**FIBRINOGEN v. PROTEIDS.**

**FIBRINOPLASTIN v. PROTEIDS.**

**FIBROIN v. PROTEIDS, Appendix C.**

**FICHELITE**  $C_{13}H_{10}$  or  $C_{11}H_{12}$ . [46°]. (above 320°). A fossil resin found in the Fichtelgebirge. It is a hydro-carbon containing from 87 to 88 p.c. carbon (Trommsdorff, A. 21, 126; Bromeis, A. 37, 304; Clark, A. 103, 236; 119, 226; Schrötter, P. 59, 37; Hell, B. 22, 498). Monoclinic prisms. Insoluble in, and lighter than, water; v. sl. sol. alcohol, v. s. sol. ether. With halogens it gives products by substitution.

**FILICIC ACID**  $C_{15}H_{12}O_4$ . *Isobutyryl-oxynaphtho-quinone?* [180° uncor.]; [185°] (L.). Occurs in the root of the common male fern (*Aspidium Filix-mas*) from which it may be extracted by dry ether. After a few days the ether deposits the acid as a greenish-yellow powder, which may be purified by washing with alcohol-ether and recrystallising from ether (Luck, A. 54, 119; B. 21, 3465; Grabowski, A. 143, 279; Dacomo, C. C. 1887, 1357; B. 21, 2962; Paternò, B. 22, 463). Minute laminae, insol. water, v. sl. sol. alcohol, sl. sol. ether, v. e. sol.  $CS_2$ , ligroin, and terpenes. After fusion it melts at 150° to 160°. Its solution reddens litmus. Potash-fusion gives butyric acid and phloroglucin. Water at 180° gives isobutyric acid and a body  $C_{15}H_{12}O_4$ .  $KMnO_4$  and  $HNO_3$  (S.G. 1.4) give isobutyric and oxalic acids. Zinc dust gives a body  $C_{15}H_{12}O_4$ — $PbA^+$ : curdy pp.

**Benzoyl derivative**  $C_{20}H_{16}O_5$ . [123°].

**Ethyl ether** [142°]. Brick-red crystals.

**Ethylene ether**. [165°].

**Propyl ether**. [158°].

**Phenyl-hydrazide**  $C_{15}H_{10}(N_2HPh)_2$ . [198°]. Red needles (from ether).

**Anilide**  $C_{15}H_{10}.NHPh$ . [140°].

**Bromo-filicic acid**  $C_{15}H_{10}BrO_4$ . [122°].

**Chlorofilicic acid**  $C_{15}H_{10}ClO_4$ . From chlorine gas and solid filicic acid. Amorphous. Its alcoholic solution gives with lead acetate a pp of  $PbA^+$ .

**Tri-chloro-filicic acid**  $C_{15}H_7Cl_3O_4$ . Formed by the action of chlorine on filicic acid suspended in water. Amorphous.— $PbA^+$ .

**FILTRATION**. The separation of a solid from a liquid by means of a membrane impervious to the solid.

**FISCIC ACID**. C. 67-33 to 67-66; H. 4-7 to 5-08. [204°]. A substance extracted from the *Fiscia parietina*, a lichen growing abundantly in Sicily on the branches of shrubs. Prepared by heating the lichen in a reflux apparatus with boiling alcohol; the black residue on treatment with ether leaves a black crystalline residue, which is frequently recrystallised free benzene in presence of animal charcoal. Yields small. Forms red-brown crystals, soluble in potash forming a rose-red salt. It exhibits considerable resemblance to chrysophanic acid.

differs from it in composition and higher melting-point (Paterno, *G.* 1882, 254).

**FISETIN**  $C_{15}H_{10}O_5$  (J. Schmid, *B.* 19, 1784; cf. Koch, *B.* 5, 285; Bolley, *Bl.* [2] 2, 479). This name was given by Chevreul to 'young fustic,' the yellow colouring matter of Fiset wood (the heart-wood of *Rhus Cotinus*, a species of sumach). It occurs as a glucoside combined with a tannin. Alkalis or acids split this compound up into the tannin and the glucoside ('fustin'). The glucoside is split up by dilute  $H_2SO_4$  into fisetin and a sugar. Fisetin crystallises from alcohol in small lemon-yellow prisms; and from HOAc in yellow prisms (containing 6aq). Sl. sol. ether, benzene, ligroin, chloroform, and boiling water, v. sol. alcohol. It begins to blacken at  $270^\circ$  but does not melt below  $360^\circ$ . It may be sublimed in small needles. Nitric acid oxidises it to oxalic and picric acids.  $H_2SO_4$  forms a sulphonic acid. It reduces Fehling's solution. Alkalis turn its alcoholic solution brownish-red. Potash-fusion gives protocatechuic acid and phloroglucin.

**Salt.**— $C_{15}H_7Na_3O_8$ : yellow needles.

**Acetyl derivative**  $C_{15}H_8Ac_3O_8$ . [ $201^\circ$ ]. Needles, sl. sol. boiling alcohol, v. sol. chloroform.

**Benzoyl derivative**  $C_{15}H_8Bz_3O_8$ . [ $185^\circ$ ]. Needles. With excess of  $BzCl$  it gives a compound [ $195^\circ$ ].

**Glucoside**  $\{C_{15}H_{11}O_5\} \cdot C_{12}H_{22}O_{11} \cdot O$ . **Fustin**. [ $219^\circ$ ]. Obtained as above. Needles; v. sol. boiling water, alcohol, and alkalis, sl. sol. ether. Lead acetate gives a yellow pp. Cupric acetate gives a brown pp.  $FeCl_3$  produces a green colour which, on addition of dilute soda, changes through violet-blue to red.

**Ethyl derivative**  $C_{15}H_{14}Et_3O_8$ . [ $107^\circ$ ]. Long pale-yellow needles.

**Methyl derivative**  $C_{15}H_{16}Me_3O_8$ . [ $153^\circ$ ].

**FIXED AIR.** The name given by Black to carbonic anhydride  $CO_2$  (v. vol. i. p. 691).

**FLAME** is gas or vapour raised to a temperature at which it becomes self-luminous. The luminosity depends essentially on the specific emissive power for light of the incandescent gas, and according to the law of exchanges is proportioned to the power of the gas to absorb the same kind of light at the same temperature. In nearly all cases, the high temperature, and hence the flame, is the result of chemical energy, displayed (in the great majority of instances) in the combination of two or more gaseous substances; hence the production of flame is in general essentially a synthetical process. There are, however, cases in which flame is produced by the breaking up of a complex molecule either into simpler forms of combination, or into its elements, as, for example, in the flame which accompanies the destruction of nitrogen trichloride where no combination or rearrangement of the constituent elements other than into molecules takes place. Flames of this character are invariably 'solid,' i.e. they are wholly composed of glowing particles, and are wanting in the internal structure which is characteristic of all ordinary flames. Flames of the synthetical class may, however, be 'solid'—such, for example, are the flames of intimate mixtures of oxygen and hydrogen, of chlorine and hydrogen, or of vapour of carbon disulphide and nitric oxide. In these cases

the chemical combination is exceedingly rapid; the heat developed is great, and the consequent molecular vibration is so intense that it becomes explosive in character.

According to Bunsen (*P. A.* 181, 161) in a mixture of carbon monoxide, or hydrogen, with oxygen in the exact quantity needed for complete combination, only one-third of the carbon monoxide or hydrogen is burnt at the maximum temperature, the remaining two-thirds at the high temperature ( $2558^\circ$ – $3033^\circ$ ) having lost the power of combination. If an indifferent gas is present the temperature of the flame is reduced, and larger quantities of the gases combine together, as much as half the amount of carbon monoxide or hydrogen combining within a range of temperature between  $2471^\circ$  and  $1146^\circ$ .

It would appear, therefore, that gases in combining together with the production of such an amount of heat as to produce flame unite *per saltum*, and that the combustion is not a continuous uninterrupted process. Thus in the case of carbon monoxide, when two vols. of this gas are mixed with one vol. of oxygen, both gases at  $0^\circ$ , and the mixture is ignited, the temperature is raised to  $3033^\circ$ , and two-thirds of the carbon monoxide is left unburnt; by radiation and conduction the temperature is lowered to  $2558^\circ$  without any combustion of the carbonic oxide; at a little below this point combustion recommences, and the temperature is again raised to  $2558^\circ$ , but not above this point. This temperature continues until half the carbon monoxide is burnt, when the combustion ceases, until by cooling and radiation the gaseous mixture has cooled to  $1146^\circ$ , and these alternate phases of constant temperature and of decreasing temperature are repeated until the whole of the combustible gas is burnt.

Bunsen has also determined the rate of propagation of the combustion of a mixture of oxygen and hydrogen, and of carbon monoxide and oxygen, mixed in the exact quantities for complete combustion. In the oxyhydrogen mixture the velocity of inflammation was 34 metres per second; in that of carbon monoxide and oxygen it was less than 1 metre per second. By adding to the mixture increasing amounts of an indifferent gas the rate is rapidly diminished until the progress of the flame throughout the mass may be followed with the eye.

The flames with which we are ordinarily familiar, as that of a candle or of coal-gas, are, however, of a very different character from the so-called 'solid' flames. In ordinary flames a stream of combustible gas comes in contact with atmospheric air at a temperature sufficiently high to effect the chemical union of the constituents of the gas with the oxygen of the air with the consequent production of heat and light. It is obvious that this union can only take place at the points of contact between the air and the gas; hence such a flame is necessarily hollow, its internal space consisting of 'combustible' gas which has not yet come into contact with oxygen in quantity sufficient to burn it. The form of the flame for any particular gas will therefore be dependent upon the mode in which the gas is caused to issue into the air, and this, in its turn, is controlled by the character of the

jet or burner, and by the pressure under which the gas is delivered.

It is obviously immaterial so far as the production of a flame is concerned whether the gas issues into the oxygen, or the oxygen into the 'combustible' gas. In either case we shall have chemical combination occurring at the point of contact of the two gaseous substances, provided the temperature be raised to that of ignition, and a flame will result from the heat of combination. In this way chlorine may be caused to burn in hydrogen, and air may seem to burn in coal-gas. Hence the terms 'combustible' and 'supporter of combustion' as applied to gases which may be made to burn in each other have no real significance; the same gas may appear to be 'combustible,' or 'to support combustion,' in accordance with the manner in which it is presented to the gas with which it combines with the production of sufficient heat to give flame.

The two main factors which determine the interaction of two gases, which are susceptible of chemical change when mixed, are temperature and degree of condensation. A stream of hydrogen issuing into the air under ordinary circumstances does not ignite. If, however, the air or the hydrogen, or both, be raised to a sufficiently high temperature just prior to admixture, chemical union will be initiated and flame will result. Hence a red-hot wire, or the flame of a taper, or electric sparks, cause the hydrogen to burn; these means have sufficed to raise the temperature of the gases to the point at which chemical combination can occur. The union of oxygen and hydrogen may, however, be effected at a low temperature under certain conditions, as, for example, by the 'catalytic' action of platinum or palladium. If a perfectly clean piece of palladium or platinum foil be suspended in a mixture of oxygen and hydrogen at the ordinary temperature, water will be seen to form on the surface of the metal in rapidly increasing quantity, the metal will become hot and will eventually raise the temperature of the gases to the point at which an almost instantaneous combination will occur, and flame and explosion will result. This power to effect union is dependent on the capacity of the metal to 'occlude' gas, and, as Berliner (*W.* 35, 791) has shown, it is more efficacious in the case of palladium than in that of platinum, in conformity with Graham's observations of the relative 'occlusive' capacities of the two metals for hydrogen. The 'catalytic' action is greatly augmented by increase of temperature, which explains the rapidly increasing rate of formation of water and the eventual explosion. The occluded hydrogen at the ordinary temperature combines with oxygen, heat is developed, and this accelerates the union of fresh quantities of the gases, the metal is thereby rapidly raised in temperature, and eventually brings the mixture to the point of inflammation. Precisely the same principle is seen at work in the well-known Döbereiner lamp, in which a current of hydrogen is caused to impinge upon a small quantity of platinum-black which has been exposed to the air. Under the influence of the finely divided metal the gases combine with the generation of sufficient heat to effect the ignition of the hydrogen as it issues into the air. Dulong and

Thenard, and Turner and Henry, have shown that copper and iron turnings, zinc foil, and even charcoal, will bring about the same result, although much less actively, at varying temperatures up to the boiling-point of mercury.

Certain gases and vapours spontaneously inflame as they issue into the air, such, for example, are boron and silicon hydrides, the dihydride of phosphorus, thio-phosphoryl fluoride, cacodyl, zinc-ethyl, &c. Thus too acetylene spontaneously inflames in chlorine, and sulphuretted hydrogen in chloric oxide. The spontaneous inflammation may in some cases be due to the fact that the ignition-temperature of the mixture is as low as that of the ordinary temperature of the air, or that the temperature has been raised to the ignition-point by a preliminary reaction between the substances. The spontaneous inflammation of 'engine-waste,' or wool saturated with oil, is due, in the first instance, to the development of heat attending the absorption of oxygen from the air by the oil. Oxygen so absorbed by oil will indeed act as energetically as if occluded by platinum. A woollen rag or a bit of blanket sprinkled with oil and suspended in a mixture of sulphur dioxide and air will rapidly 'tinder' from the formation of oil of vitriol.

We have as yet no very exact information concerning the ignition-temperatures of gases. The experimental difficulties in the way of carrying out such determinations are very considerable. A. Mitscherlich has described a method (*Fr.* 16, 67) of ascertaining the ignition-point, but no determinations by means of it have yet been published. It is, however, certain that the ignition-temperatures of gaseous mixtures are as a rule by no means so high as is commonly supposed, and they lie within extremes of temperature admitting of comparatively easy determination. When once initiated, the continuance of the combination of unlimited amounts of the constituents of a combustible mixture, or in other words the continued existence of a flame, depend primarily upon the condition that the combining gases are maintained at the temperature required to bring about their union. Any agency or condition which lowers the temperature below this point will extinguish the flame. A coal-gas flame is extinguished by a cold mass of copper, and a candle flame by a helix of cold copper wire. The metal abstracts sufficient heat from the gases to lower their temperature below the point of combination. If the metal is heated prior to its introduction into the flames they are not extinguished.

The cooling action of metal is made use of in the Hemming safety-jet used for burning mixtures of oxygen and hydrogen, but a far more important application of it is seen in the Davy safety-lamp. This is simply a small oil lamp surrounded by a cylinder of wire gauze. If the lamp is introduced into an explosive mixture of fire-damp and air, combination occurs within the cylinder, but the flame is prevented from traversing the gauze by the cooling action of the metal. Any circumstance which causes the gauze to become hot, or which prevents it from exerting its specific cooling action, renders the lamp unsafe. Thus if the flame impinge on the wire gauze so as to heat it to redness, &

If the burning lamp be held in a current of air and fire-damp exceeding in velocity six feet per second, or if it be struck by a sound wave of sufficient intensity, the flame will pass through the meshes, and may ignite an explosive mixture on the outside of the cylinder.

A flame may be extinguished, however, in other ways than by the cooling action of metals, as, for example, by mixing the combustible gases with a sufficiently large quantity of an indifferent gas which will act by absorption of heat, in the same way as metal. The effect even of small quantities of indifferent or chemically inactive gases in lowering the temperature of a flame is very marked, and is well illustrated in the different characters of the flame of hydrogen burning in air and in oxygen. In extinguishing a flame, say of a candle or coal-gas, by 'blowing it out,' the puff of air acts partly by suddenly scattering the glowing gases from the area of supply and partly by its cooling action. Although oxygen is essential to the existence of the oxyhydrogen flame, it is readily possible to extinguish the flame by an excessive supply of that gas within the jet. The power which an indifferent gas possesses in destroying flame has received important practical applications in several fire-extinguishing apparatuses.

If the flame of a candle or of coal-gas be closely examined it will be seen that the one does not touch the rim of the burner nor the other the wick (Blochmann, A. 168, 345). The intermediate space in the case of coal-gas may be increased by mixing it with an indifferent gas, as nitrogen or carbon dioxide. These phenomena are due to the cooling effect of the wick or the burner. Whenever a cold object touches a flame, a dividing space, similar to that noticed between flame and burner, is observed, the size of which is dependent on the coldness of the object or its specific heat, and the dilution of the burning gas. A thick metallic wire, brought into a flame diluted with carbon dioxide, causes a clear space around itself, which increases with the proportion of the indifferent gas. The diluting gas lowers the temperature of the flame, by diffusing the heat needed to maintain a given quantity of the coal-gas in a state of combustion throughout a greatly increased volume of gas. If the temperature of the flame is already low, the further decrease resulting from the introduction of the cold object suffices to cool a comparatively large extent of gas below the ignition-point, and hence to extinguish the flame in the cooled space.

Rarefaction of the gases prevents the continuance of combustion by retarding combination, whereby the temperature of the gases sinks below that necessary to effect union. A jet of hydrogen issuing into rarefied air gives at first an increased size of flame, but it ceases to burn when the air is rarefied to  $\frac{1}{10}$ th its ordinary pressure, and a mixture of 2 vols. of hydrogen and 1 vol. of oxygen is not explosive when rarefied to  $\frac{1}{10}$ th its ordinary density. By mixing oxygen with an indifferent gas many phenomena of combustion are immediately arrested, unless some extrinsic agency is at work to maintain or even raise the temperature. The combustion of iron wire in oxygen stops almost immediately when the glowing metal is withdrawn into the air.

On the other hand, instances are known in which sudden rarefaction will produce spontaneous ignition even at the ordinary temperature. Thus pure phosphine mixed with oxygen is not spontaneously inflammable at ordinary temperatures and pressures, but on suddenly expanding the mixture it inflames with explosive violence. In the same way thiophosphoryl fluoride, if mixed with an indifferent gas and thereafter with oxygen, will detonate on a sudden diminution of the pressure. These phenomena are in all probability connected with the extreme instability of these gases, and are akin to the cases of decomposition by shock which have been studied by Berthelot and others (v. Explosions).

It has already been stated that the form of a steady continuous flame depends upon the mode in which the combustible gas issues into the air, and this is dependent upon the form and size of the jet, or, in the case of a candle, of the wick. The size of the flame from gas issuing at a constant rate is dependent on the temperature, pressure, and relative diffusibilities, of the combining substances. By increasing the amount of oxygen in the air the size of a flame may be considerably diminished. This fact is well illustrated by plunging a jet of hydrogen burning under constant pressure in air into oxygen gas. The increased size of the flame under ordinary conditions is due to the fact that the air contains only one-fifth of its volume of oxygen; the 'combustible' gas has to seek, therefore, over a larger area for the oxygen required for combination. The size of a flame is also necessarily determined by the volume of oxygen needed for the complete combustion of the inflammable gas. Thus equal volumes of hydrogen and of ethylene passing through the same jet and at the same rate into oxygen will give flames of very different size: the hydrogen, which needs only half its volume of oxygen to burn it, forms a much smaller flame than the ethylene, which requires three times its volume. On the other hand, oxygen burning in hydrogen gives a larger flame than when burning in marsh gas; in the former case the oxygen needs 2 vols. of hydrogen for its combustion; in the latter only half a volume of marsh gas.

The temperature of flames is extremely variable. Some, like that of sulphur burning in air, are comparatively low; others furnish us with some of the highest temperatures of which we have any practical knowledge. The temperature of a flame depends mainly upon the heats of combination of the constituents and the specific heats of the products of combustion. Flames which depend upon the presence of oxygen are much hotter when the combustion takes place in an atmosphere of the pure gas than in air. In the latter case the oxygen is mixed with four times its volume of nitrogen, which plays no part in the chemical reaction, and therefore contributes nothing to the heating effect, but on the contrary abstracts a considerable amount of heat from the products of combustion, and thereby lowers the temperature of the glowing mass of gas. Hence sulphur burning in oxygen gives a much hotter flame than when burning in air, and the oxyhydrogen flame is much hotter

Flame of hydrogen burning in air . 2,024°  
 " " " oxygen 2,814°  
 " carbonic oxide burning in air 1,997°  
 " " " oxygen 3,003°.

The conditions under which a flame is produced not only modify its temperature, but also, as an effect of temperature, its colour. Thus the prevailing tint of sulphur burning in air is blue, and the mantle is comparatively small and of a violet colour. In oxygen the flame becomes hotter, and the violet colour is more pronounced. Precisely the same change is produced by heating the air or by burning a jet of heated sulphur vapour. Cold carbonic oxide gives a blue flame in air, but it becomes yellowish-red if the gas be previously heated.

The flame of a candle, whether of wax, tallow, or paraffin, is seen to consist of four distinct cones, which are comparatively sharply defined, and which are rendered evident by their different appearances. Immediately surrounding the wick is a dark inner cone consisting of unburnt gases or vapours distilled from the fatty matter raised by the capillary action of the wick from the reservoir of melted material at its base. Below the inner cone is a light-blue zone of small area consisting of combustible matter from the wick, which has become mixed with an amount of oxygen sufficient to burn it completely to non-luminiferous gases. Surrounding the inner cone is a bright luminous area, from which the greater part of the light emitted by the flame is derived. This area constitutes the main meeting-place of the combustible gases with the oxygen, and hence chemical combination is here most vigorous. Surrounding the luminous area, which seems to constitute the greater portion of the visible flame, is an envelope or mantle of a faint yellowish colour and of feeble luminosity; this consists of the final products of combustion of the constituents of the luminous cone mixed with atmospheric air heated to incandescence. Owing to the intense glare of the luminous cone the feebly luminous mantle is not readily perceived, but it may be rendered evident by holding a piece of card of the shape of the flame in such a manner as to hide the luminous cone, when the mantle is seen lining the outer edge of the cone. The fact that the candle flame is hollow, and that the internal cone immediately surrounding the wick consists of comparatively cold unignited gas free from oxygen, may be demonstrated by thrusting a fragment of burning phosphorus into the cone, when its combustion ceases. A piece of stiff thick paper thrust down on the flame to the level of the dark internal area is seen to be charred on the upper surface in the form of a ring; if the paper be placed simply across the luminous area and above the dark cone the charring is simply a circular patch.

In other steady, continuous flames these areas or zones are very different in character and in number. In some the luminous cone is absent, and others have no mantle; all have, of course, the dark internal cone, and the majority have an area corresponding to the blue zone in

the candle flame. In an alcohol flame the internal cone is large, owing probably to the ready volatilisation of the combustible vapour; the luminous cone is small, and the mantle seems to be largely developed. The flame of carbon monoxide consists of a dark internal cone of unburnt gas surrounded by a yellowish-red mantle somewhat ill-defined at its external edge, and at the base is a comparatively large blue zone.

Attempts have been made by Hilgard (*A. 92, 129*), Lafodt (*P. A. 99, 389*), Blochmann (*A. 158, 295*), and others, to study the nature of the chemical process in flames of candles and of coal-gas, by aspirating the gases from different parts of the flame and analysing them. Such investigations can only give a very partial conception of the changes which occur or have occurred in the different areas of the flame owing to the intense molecular movements, due to the high temperature and specific differences of diffusive power, of the gaseous constituents. Nevertheless it is possible to obtain some idea of the manner in which the several combustible gases in such a complex mixture as that of coal-gas, or of the gas obtained by the distillation of wax or tallow, behave towards oxygen, and to trace the rates at which they are severally burnt. Thus, broadly speaking, it is found that of these gases, the hydrogen up to a certain point is most rapidly consumed, then the carbonic oxide, next the marsh gas, while the heavy hydrocarbons burn comparatively slowly. The amounts of these gases burnt, and especially of the hydrogen and carbonic oxide, are, however, modified by processes of dissociation, and by the mutual action of the products of combustion at high temperatures; at very high temperatures water vapour and carbon dioxide are dissociated, while carbon monoxide is formed by the action of separated carbon upon carbon dioxide. The process of breaking up the hydrocarbons is one of gradual degradation, the higher members of the paraffin series being probably resolved into olefines and paraffins of lower molecular weight:

as in the case of butane, which is known to be resolved into ethane and ethylene,  $C_4H_{10} = C_2H_6 + C_2H_4$ . At a sufficiently high temperature ethylene is further broken up as follows:

On the other hand, at high temperatures marsh gas is known to form naphthalene  $C_{10}H_8$  and acetylene; while at still higher temperatures it is resolved into carbon and hydrogen.

The main cause of the luminosity of a candle-flame, and indeed of all our ordinary illuminating flames, was first traced by Davy as the outcome of the experiments which led him to the invention of the safety lamp. It is, to use his own words, 'owing to the *decomposition* of a part of the gas towards the interior of the flame, where the air was in smallest quantity, and the deposition of solid charcoal, which first by its ignition, and afterwards by its combustion, increases in a high degree the intensity of the light' (7r. 1817, 45, 77). The proofs that solid carbon is present in luminous hydrocarbon flame

are the following (v. especially Heumann, P. M. 1877).

1. Chlorine causes an increase in the luminosity of feebly-luminous or non-luminous hydrocarbon flames. Since chlorine decomposes hydrocarbons at a red heat with separation of carbon, it follows that the increase in luminosity is due to the production of solid carbon particles.

2. A rod held in the luminous flame soon becomes covered on its lower surface, i.e. the surface opposed to the issuing gas, with a deposit of soot. The solid soot is driven against the rod. If the soot existed as vapour within the luminous flame, its deposition would be due to a diminution of the temperature of the flame, and would, therefore, occur on all sides of the rod.

3. A strongly heated surface also becomes covered with a deposit of soot. This result could not occur if the deposit were due to the cooling action of the surface.

4. The carbon particles in the luminous flame are rendered visible when the flame comes in contact with another flame, or with a heated surface. The separated particles are agglomerated into larger masses, and the luminous mantle becomes filled with a number of glowing points, giving a very coarse-grained soot.

5. The transparency of a luminous flame is no greater than that of the approximately equally thick stratum of soot which rises from the flame of burning turpentine, and which is generally allowed to contain solid particles. A flame of hydrogen made luminous with solid chromic oxide, which is non-volatile, is as transparent as the hydrocarbon flame.

6. Flames which undoubtedly owe their luminosity to finely divided solid matter produce shadows in sunlight. The only luminous flames incapable of producing shadows are those consisting of glowing gases and vapours.

7. Luminous hydrocarbon flames produce strongly marked shadows in sunlight; these flames, therefore, contain finely divided solid matter. This solid matter must be carbon, since no other substance capable of remaining solid at the temperature of these flames is present (Heumann). Moreover, if the soot in luminous flames is present as vapour, a high temperature after condensation should again cause it to assume the gaseous condition, but soot is absolutely non-volatile even at the highest temperatures.

The presence of solid matter is, however, not the sole cause of the luminosity of a candle or hydrocarbon flame, since a small portion of the light is derived from the incandescence of the gaseous matters. Methane, which when burning under ordinary conditions gives no deposit of soot, still affords a flame of considerable illuminating power (equal to 5.2 candles according to Lewis T. Wright, O. J. 47, 200). Bright flames may indeed be produced without the intervention of solid matter. Arsenic burns in oxygen with a bright flame, although the product of the combustion (arsenious oxide) is volatile at the temperature of its formation. A mixture of nitric oxide and carbon disulphide burns with a brilliant light although no separation of solid matter occurs. It has already been pointed out that substances burning in oxygen give much hotter flames than when burning in air, and it is also found that the flames in oxygen are much

more luminous than those in air. Hence the temperature of a flame very considerably affects its light-giving power. E. Frankland has pointed out the connexion between the luminiferous character of flames and the density of their constituents, as is exemplified by the greater illuminating power of a hydrogen flame in chlorine than in oxygen. The luminosity of a flame is increased by condensing the surrounding atmosphere and diminished by rarefying it. Boyle, in 1658, minutely described the appearance of a candle-flame as seen under diminished pressure in the receiver of his 'new pneumatical engine.' E. Frankland found that candles give much less light when burning at the top of Mont Blanc than in the valley below, although the rate of combustion is not much affected by the difference in the density of the air. The flame of arsenic burning in oxygen is greatly diminished in brightness by rarefying the oxygen, and the flame of an alcohol lamp increases greatly in luminosity when burning in condensed air. Under a pressure of 10 atmospheres the flames of hydrogen and of carbon monoxide become very bright and give continuous spectra, and an electric spark increases in luminosity with the density of the gaseous medium through which it passes (Frankland, Pr. 16, 419).

Similar observations have been made by L. Cailletet (A. Ch. [5] 6, 429), who found that the flames of candles, sulphur, potassium, and carbon disulphide, but not of phosphorus, burned in gradually compressed air with continually increasing intensity of illumination up to pressures of 35 atmos. On the other hand, Wartha (J. pr. [2] 14, 84) found that the flame of a stearin candle burning in air under a pressure of 1.95 at. is from 13 to 17.4 p.c. less luminous than when burning in air of ordinary density. At the higher pressure candles burn with a dull yellowish-red smoky flame fully twice as long as that of the same candles burning in the open air. Candles burning at a constant pressure of 90 mm. give a large, clear, non-luminous flame, consisting of an inner bluish-green cone, surrounded by a violet zone, and inclosed by a very faint violet mantle. The non-luminosity of flame under low pressures was supposed by E. Frankland to be due to the increased mobility of the oxygen molecules in the rarefied air in consequence of which they were able to penetrate more freely into the interior of the flame. According to Wartha, the difference is to be attributed to the effect of the pressure on the dissociation-point of the burning substance. When candles are burned in air, under very high pressure, the dissociation of the hydrocarbons takes place more rapidly than the products can be burned, and the flame becomes smoky; under reduced pressure the reverse is the case.

A comparatively small admixture of air greatly impairs the illuminating power of coal-gas. Stillmann & H. Wurtz (Am. S. [2] 48, 40) found that on adding varying quantities of air to a coal-gas having an illuminating value of 14.8 candles the loss of light was as follows:

Added air	Percentage loss of light
3.00 p.c.	15.69
4.98 "	23.68
11.71 "	41.46
16.18 "	57.63

in adding about 25 p.c. of air the illuminating power diminished 84 p.c. With such an admixture coal-gas burns with a smokeless and practically non-luminous flame.

It has been shown that a coal-gas flame burning in air becomes non-luminous by previous admixture with nitrogen, hydrochloric acid, carbon dioxide (Knapp), carbon monoxide, hydrogen (Blochmann), or even steam (Sandow). P. F. Frankland found that while the illuminating power of ethylene was diminished after a certain point by admixture with ordinarily non-luminous combustible gases, the loss of light depended on the nature of the diluent, and was greatest with carbonic oxide and least with marsh gas. An admixture of the combustible gas up to 40 p.c. hardly affects the illuminating power of the ethylene (*C. J.* 45, 39). Mixtures of oxygen with ethylene in quantity insufficient to form an explosive mixture possess a greater illuminating power than pure ethylene. By the addition of carbon dioxide, nitrogen, or aqueous vapour, the illuminating power of ethylene is diminished. These gases act partly by dilution, and partly by cooling; the cooling action is proportional to the specific heats of the gases, but in the case of carbon dioxide and aqueous vapour it is augmented by the absorption of heat which takes place in the dissociation of the aqueous vapour, and in the reduction of the carbon dioxide to carbon monoxide (P. F. Frankland, *C. J.* 45, 236).

Wibel has shown that a mixture of coal-gas and air, which when burnt under ordinary conditions is non-luminous, may be made to give a luminous flame if it is heated previous to inflammation (*B.* 8, 226); and Heumann (*A.* 181, 129; 182, 1; 183, 102; 184, 206) has proved that the luminosity is actually due to the added heat, and not to any alteration in the composition of the gaseous mixture in consequence of the heating.

These observations have an important bearing on the theory of the flame of the Bunsen lamp. The nature of the chemical changes in this flame has been studied by Blochmann (*A.* 168, 295). The feebly luminosity of the Bunsen flame is due (1) to a rapid oxidation of luminiferous material to gases of feebly illuminating power by the oxygen in the admixed air; (2) to the presence of diluting gases which of themselves reduce the illuminating power; and (3) to the heat withdrawn by the indifferent gases, as nitrogen, and the products of combustion, carbon dioxide and water. The loss of luminosity is not due to any one of these causes acting singly. A flame of mixed coal-gas and air has a higher temperature than that of the undiluted coal-gas, but it requires a still higher temperature in order that a separation of carbon shall occur.

When the flame of a Bunsen lamp retreats down the tube and burns at the jet at the bottom a much smaller quantity of air passes into the tube. Under normal conditions 1 vol. of the gas becomes mixed with about 2½ vols. of air; when burning at the bottom the gas becomes mixed with only about 1½ vols. of air. The effect of this diminished amount of air is a large increase in the amount of carbon monoxide, together with the production of notable quantities of acetylene, to which substances the extremely disagreeable nature of the gases evolved from

the burner under these circumstances is due. (Compare Thorpe 'On the Theory of the Bunsen Lamp,' *C. J.* 1877, 1, 627.) T. E. T.

#### FLAVANILINE $C_{17}H_{11}N_3$ , i.e.

**Formation.**—1. By heating equal mols. of ortho- and para-amidoacetophenone with an equal weight of zinc-dust at 50°–100°; the yield is 50 p.c.—2. By nitration and reduction of flavoline. 3. By heating o-amido-acetophenone to 230° with  $ZnCl_2$ .—4. By the action of acetyl chloride on aniline sulphate.

**Preparation.**—By heating acetanilide with  $ZnCl_2$  for several hours at 250°–270°, the melt is dissolved in boiling dilute HCl, sodium acetate added, and the product salted out (O. Fischer a. Rudolph, *B.* 15, 1500).

**Theory of formation from acetanilide.** At the temperature employed the acetanilide undergoes isomeric change, being converted into a mixture of o- and p-amido-acetophenone, and the latter (as shown in formation 1) gives the dyestuff by the elimination of  $2H_2O$  from two mols. by means of the  $ZnCl_2$ :

**Constitution.**—Contrary to the earlier supposition, flavaniline has the  $NH_2$  group in the para-position not in the ortho-. The fact that a small quantity of the dyestuff is formed by heating ortho-amido-acetophenone with  $ZnCl_2$  at 250° must be due to an isomeric change of a portion of the o-amido-acetophenone into p-amido-acetophenone.

**Properties.**—Long colourless needles. Distils undecomposed at a high temperature. Sol. alcohol, insol. water. Strong di-acid base. The salts form a splendid yellow dyestuff of green fluorescence. By the action of nitrous acid it yields flavenol.

**Salts.**— $B^+H_2Cl_2$ : colourless soluble needles. — $B^+HCl$ : yellowish-red soluble prisms. — $B^+H_2Cl_2PtCl_6$ : sparingly soluble crystalline pp.

**Reactions.**—It cannot be reduced to a hydride by tin and HCl; but on treatment with alcohol and sodium it yields a fluid base, the salts of which are colourless, and forms a crystalline nitrosamine. Heated with glycerin, nitrobenzene and  $H_2SO_4$  it yields a methyl-diquinoline [138°] (O. Fischer, *B.* 19, 1036).

**Reference.**—Ethyl-flavaniline.

Pseudo-flavanilin  $C_{17}H_{11}N_3$ , i.e.

**Preparation.**—By leading oxygen over a mixture of quinoline and o-toluidine hydrochloride heated to 180° on platinized asbestos (Weidel a. Bamberger, *M.* 9, 99).

**Properties.**—Flexible, hair-like needles (from water). Converted by  $HNO_3$  into pseudo-flavenol  $C_{17}H_{11}NOH$ , which on further oxidation gives quinaldinic acid  $C_{17}H_{11}NO_3$ .

**Salts.**— $B'HCl$ : long needles.— $B'HCl$ : small yellow monoclinic needles.— $B'H.PtCl_4$ .

**Acetyl derivative**  $C_{16}H_{11}AcON$ . [177°].

**FLAVANTHRACENE-DI-SULPHONIC ACID** v. ANTHRACENE-DI-SULPHONIC ACID (*flav*).

**FLAVENOL**  $C_{16}H_{11}NO$  *i.e.*

$C_6H_5 \begin{matrix} \diagup OMe:OH \\ \diagdown N = C_6H_5.OH [1:4]. [238^\circ]. \end{matrix}$  Formed by the action of nitrous acid on flavaniline. Sublimable. Colourless iridescent plates. Sol. alcohol and aqueous NaOH. Has both phenolic and basic properties.

**Reactions.**—On distillation with zinc-dust it gives flavoline. With acetic anhydride it forms a substance crystallising in needles [128°], which distils undecomposed (O. Fischer a. Rudolph, *B.* 15, 1502). On oxidation with alkaline  $KMnO_4$  it is converted successively into lepidine-carboxylic acid, picoline-tri-carboxylic acid, and finally pyridine-tetra-carboxylic acid (O. Fischer a. Täuber, *B.* 17, 2925).

**Salts.**— $B'HCl^+$ : long colourless soluble needles.— $B'H_2SO_4^+$ : colourless needles.— $B'H_2Cl.PtCl_4^+$ : yellow sparingly soluble needles.

**Acetyl derivative**  $C_{16}H_{11}N(OAc)$ : long needles or small plates [128°] (Besthorn a. O. Fischer, *B.* 16, 89).

**Pseudo-flavenol**  $C_{16}H_{11}NO$  *i.e.*

$C_6H_5 \begin{matrix} \diagup CH:CH \\ \diagdown N = C_6H_5.Me.OH [196^\circ]. \end{matrix}$

**Preparation.**—From pseudo-flavaniline by the action of nitrous acid; crystalline pseudo-flavenol [89°] and nitro-pseudo-flavenol are also formed. It is separated from these by shaking with ether, which extracts the oxy-compound, and then ppg. the impure pseudo-flavenol by  $CO_2$ . Crystallised from absolute alcohol.

**Properties.**—Plates. Sol. hot alcohol, ether, benzene, and chloroform. Oxidised by  $CrO_3$  to quinoline (*Py.* 3)-carboxylic acid [157°]. It is reduced by zinc-dust to the base pseudo-flavoline  $C_{16}H_{11}N$ , ortho-cresol, and quinoline. Tin and HCl convert it into a tetrahydro-compound, which, when fused with potash, is oxidised to  $\alpha$ -oxy-iso-phthalic,  $p$ -oxy-benzoic, and salicylic acids (Weidel a. Bamberger, *M.* 9, 99).

**Salts.**— $B'HCl2aq$ : pale yellow needles.— $(BHCl)_2PtCl_4$ : yellow crystalline powder.

**Acetyl derivative**  $C_{16}H_{11}NOAc$ : [106°]; plates.

**Nitro-pseudo-flavenol**  $C_{16}H_{11}(NO_2)NO$ . [160°].

**FLAVINE** v. DI-AMIDO-BENZOPHENONE.

**FLAVOLDINE**. A name proposed by Meldiss (*C. N.* 50, 267) to denote azo-bases of the form  $NH_2R''N_2R'NH_2$ , isomeric with the chryso-idines.

**FLAVOL** v. DI-OXY-ANTHRACENE.

**FLAVOLINE** v. (*Py.* 3:1)-PHENYL-METHYL-QUINOLINE.

**FLAVOPURPURIN** v. TRI-OXY-ANTHRACENE-QUINONE.

**FLAVOQUINOLINE** v. (*Py.* 1)-METHYL-(*Py.* 3:5:8)-QUINOLINE.

**FLAVAL** v. GUTTA PERCHA.

**FLUO.** Use of this prefix applied to inorganic compounds: for fluo-salts v. the salts to the name of which fluo- is prefixed. Thus, fluo-nitobates, fluo-silicates, and fluo-stannates will be described under NITOBATES, SILICATES,

and STANNATES, and these salts will be found under the general headings NITRUM, SILICUM, and TIN. M. M. P. M.

**FLUO-BENZENE** v. FLUORO-BENZENE.

**FLUOBENZOIC ACID** v. FLUOROBENZOIC ACID.

**FLUOBORIC ACID** and **FLUOBORATES**  $H_2B_3O_6.6HF$  and  $M.B_3O_6.6HF$  (v. vol. i. p. 530).

**FLUORANILINE** v. FLUORO-ANILINE.

**FLUORANTHENE**  $C_{16}H_{10}$  *i.e.*

(Fittig a. Liepmann, *B.* 12, 164). *Idryl*. [110°]. (251° at 60 mm.). V.D. 6.64 (calc. 6.57).

**Occurrence.**—In coal-tar (Fittig a. Gebhard, *A.* 193, 142). Found also to the extent of 3 p.c. amongst the solid hydrocarbons obtained in Idria in distilling mercury from its ore (Goldschmidt a. Schmidt, *M.* 2, 1), and in American petroleum (Prunier, *Bl.* [2] 31, 293).

**Preparation.**—Crude pyrene from coal-tar is converted into the picric acid compound by treatment with an alcoholic solution of picric acid. The picric acid compound of fluoranthene is more soluble in alcohol than that of pyrene. The hydrocarbon is liberated from this compound by  $NH_3$ , and is recrystallised from alcohol. Fluoranthene may also be separated from pyrene by fractional distillation under 60 mm. pressure when pyrene boils 10° higher (Fittig a. Liepmann, *A.* 200, 1).

**Properties.**—Large colourless monoclinic plates (from dilute alcohol)  $a:b:c = 1.495:1.1:0.25$ ;  $\beta = 82^\circ 50'$ ; or thin needles (from alcohol). Sl. sol. cold, v. sol. hot, alcohol; v. sol. ether,  $CS_2$ , and HOAc. Warm conc.  $H_2SO_4$  dissolves it, forming a blue solution. Its picric acid compound  $C_{16}H_9O_6H_3(NO_3)_3$  [183°] forms long reddish-yellow needles, which may be recrystallised from alcohol without decomposition.

Tri-chloro-fluoranthene  $C_{16}H_7Cl_3$ . [above 300°]. Needles (Goldschmidt, *M.* 1, 222).

Di-bromo-fluoranthene  $C_{16}H_8Br_2$ . [205°]. From fluoranthene in  $CS_2$  and Br (F. a. G.). Light-yellow needles (from  $CS_2$ ).

Tri-bromo-fluoranthene  $C_{16}H_5Br_3$ . From fluoranthene in HOAc and Br. Needles. Does not melt below 345° (G.).

Tri-nitro-fluoranthene  $C_{16}H_5(NO_3)_3$ . [above 300°]. From fluoranthene and fuming  $HNO_3$ . Minute yellow needles. Insol. ordinary solvents, sol. hot  $HNO_3$ .

Fluoranthene dihydride  $C_{16}H_{12}$ . [76°]. From fluoranthene by treatment of its alcoholic solution with sodium amalgam, or by heating with  $HIAg$  and red phosphorus at 180° (Goldschmidt). Needles (from alcohol). Its picric acid compound  $C_{16}H_9O_6H_3(NO_3)_3$  [185°] crystallises from alcohol in red needles.

**Fluoranthene osethydride**  $C_{14}H_{12}$ . (311°). From fluoranthene,  $HIAq$ , and red phosphorus at 250° (G.).

**Fluoranthene disulphonic acid**  $C_{14}H_8(SO_3H)_2$ . From fluoranthene (1 pt.) and  $H_2SO_4$  (2 pts.) at 100° (G.). Unstable syrup. Potash-fusion gives crystalline  $C_{14}H_6O_8S_2[246^\circ]$ .— $K_2A''aq$ .— $CaA''4aq$ .— $BaA''2\frac{1}{2}aq$ ; m. sol. water.— $CdA''2\frac{1}{2}aq$ . On distilling the K salt with  $KCy$  and fusing the product with  $KOH$  there is formed the carboxylic acid  $C_{14}H_6CO_2H[165^\circ]$ .

**Fluoranthene-quinone**  $C_{14}H_6O_2$ . [189°]. Formed, together with a large proportion of di-

by oxidising fluoranthene with chromic acid mixture (F. a. L.). After removing the acid by aqueous  $Na_2CO_3$ , alcohol extracts the crystalline compound  $C_{14}H_4O_2(C_6H_5)_2[102^\circ]$  whence aqueous  $NaHSO_3$  extracts the quinone. On addition of  $HCl$  to the solution in  $NaHSO_3$ , there are ppt. nearly colourless needles, apparently consisting of the hydroquinone; these are converted in great part into the quinone during recrystallisation from alcohol, or more quickly by oxidation with  $FeCl_3$ . Small red needles (from alcohol); m. sol. alcohol and  $HOAc$ .

**phenylene-methane**. Mol. w. 166. [113°]. (c. 302°) (A.); (295° i. V.) (F. a. S.). V.D. 5.77 (calc. 5.78).

**Occurrence**.—In the portion of coal-tar boiling between 300° and 400° (Berthelot, *A. Ch.* [4] 12, 222; Barbier, *A. Ch.* [5] 7, 472).

**Formation**.—1. From diphenylene ketone by distilling with zinc-dust (Fittig, *B. 6*, 187; Fittig a. Schmitz, *A.* 193, 134) or by heating with  $HIAq$  and amorphous phosphorus at 160° (Graebe, *B.* 7, 1625).—2. By passing diphenyl-methane through red-hot tubes (Graebe, *A.* 174, 194).—3. From diphenyl and  $CH_2Cl_2$  under the influence of  $AlCl_3$  (Adam, *Bl.* [2] 47, 686).—4. By distilling the di-carboxylic acid with lime (Bamberger a. Hooker, *B.* 18, 1036).—5. By distilling pheanthraquinone with lime (Anschütz a. Schultz, *A.* 196, 44).—6. By heating ellagic acid with zinc-dust in a current of hydrogen (Barth a. Goldschmidt, *B.* 11, 846).

**Preparation**.—By fractionally distilling the hydrocarbons contained in coal-tar about 20 litres of a portion boiling from 300° to 320° is collected; this is solidified by cold, pressed, and redistilled; a fraction 290° to 310° (10 litres) is then obtained by distillation. After one more distillation the fraction 295° to 305° is recrystallised successively from alcohol-benzene, alcohol, and  $HOAc$  (Barbier). Still further purification may be effected by means of the picric acid compound.

**Properties**.—Very small white plates (by sublimation) exhibiting, when not perfectly pure, violet fluorescence. If recrystallised several times from alcohol and then from glacial acetic acid it is no longer fluorescent (Hodgkinson a. Matthews, *C. J.* 43, 168). V. sol. ether, benzene,  $CS_2$ , and hot alcohol, sl. sol. cold alcohol.

**Reactions**.—1. Boiling with  $CrO_3$  in  $HOAc$

forms diphenylene ketone, but no quinone.—2. *Potash-fusion* gives di-oxy-diphenyl [98°] and other products.—3. When its vapour is passed over heated *lead oxide* there are formed two hydrocarbons,  $C_{14}H_{12}$  and  $C_{14}H_{10}$ . The latter forms red trimetric crystals (from  $HOAc$ ) [188°] (above 360°); gives an unstable picric acid compound [178°]; and is reduced in alcoholic solution by sodium-amalgam to colourless  $C_{14}H_{12}$  [242°] (De la Harpe a. Van Dorp, *B.* 8, 1049). The hydrocarbon  $C_{14}H_{10}$  forms long yellow needles (from benzene-alcohol) [270°].—4. When fluorene is passed over red-hot  $MnO_2$ , a red mass is obtained, and if this be freed from fluorene by heating somewhat above 300° and from the red body by washing with ether, there is left the hydrocarbon  $C_{14}H_{10}$  [246°] termed 'para-difluoryl.' It forms long thin prisms, v. sl. sol. cold ether, m. sol. hot  $HOAc$ . It decomposes above 250°. It forms a tetra-bromo-derivative [302°], and is oxidised by  $CrO_3$  in  $HOAc$  to  $C_{14}H_8O_2$  [255°]. Two other hydrocarbons,  $C_{14}H_{12}$ , appear to accompany the one described [246°] in the red mass (Hodgkinson, *C. J. Proc.* 1, 36).—5. Conc.  $HIAq$  (40 pts.) at 275° forms  $C_{14}H_{12}$  (240°), hexane and heptane being also formed according to Berthelot (*A. Ch.* [5] 7, 510).—6. On adding the calculated quantity of bromine dissolved in  $CS_2$  to a solution of fluorene in  $CS_2$ , dibromo-fluorene  $C_{14}H_8Br_2$  [167°] is formed. It crystallises from  $CS_2$  in monoclinic forms. By treatment with more  $Br$  in the cold there is produced the tri-bromo-fluorene  $C_{14}H_5Br_3$  [162°] (v. Di-bromo-fluorene). Bromine vapour passed into a cold solution of fluorene in  $CS_2$ , forms light-yellow needles of  $C_{14}H_5Br_3$ , which is quickly converted by alcoholic  $KOH$  into di-bromo-fluorene. By the simultaneous action of bromine and  $KOH$  on fluorene there is formed a bromo-fluorene [104°] (Hodgkinson, *C. J. Proc.* 1, 36).—7. Chlorine passed into a solution of fluorene in  $CS_2$ , forms  $C_{14}H_7Cl_2$  [118°] and  $C_{14}H_7Cl_3$  [147°] (v. Di-chloro-fluorene).—8. A mixture of fuming nitric acid and  $HOAc$  forms nitro-fluorene  $C_{14}H_9(NO_2)$  [154°] and di-nitro-fluorene  $C_{14}H_7(NO_2)_2$  [201°] (v. Nitro-fluorene). The former may be reduced by tin and  $HCl$  to p-amido-fluorene [125°], which crystallises in needles and forms an acetyl derivative [188°] (Strasburger, *B.* 17, 108). Di-amido-fluorene  $C_{14}H_7(NH_2)_2$  [157°] is obtained by distilling di-amido-diphenic acid with lime; its acetyl derivative [250°] crystallises in leaflets (Schultz, *A.* 203, 99).—9. Treated with phenyl-acetic chloride and  $AlCl_3$ , it gives the ketone  $C_{14}H_8 \cdot CO \cdot CH_2 \cdot C_6H_5$  [196°] which crystallises in small tables, sl. sol. cold alcohol and ether (Päpcke, *B.* 21, 1341). This ketone is converted by benzyl chloride and  $NaOEt$  into  $C_{14}H_8 \cdot CO \cdot CHPh \cdot CH_2 \cdot C_6H_5$  [160°] which crystallises from alcohol in slender needles.

**Picric acid compound**  $C_{14}H_9O_6H_2(NC_3)_2 \cdot OH$ . [82°]. Obtained by adding picric acid to an ethereal solution of the hydrocarbon. Reddish-brown prisms. Decomposed by boiling with water or alcohol.

**Picryl chloride compound**  $C_{14}H_9 \cdot C_6H_4(NO_2)_3 \cdot Cl$ . [70°]. Orange needles (Liebermann a. Palm, *B.* 8, 877).

**Fluorene sulphonic acid**  $\cdot C_{14}H_8SO_3H$ . From fluorene in  $CHCl_3$  and  $ClSO_3H$  (Hodgkinson a. Matthews, *C. J.* 43, 166). Gummy. V. sol.

water. Fused with KOH at a little above 400° it forms two tri-oxy-diphenyls (q. v.), for not only is SO<sub>3</sub>H displaced by OH but CH<sub>3</sub> is displaced by 2(OH).

Salts.—KA': minute cubes.—BaA', 2aq. —CdA', 6aq.

Isomeride of fluorene. — DI-PHENYLENE-METHANE.

• FLUORENE ALCOHOL v. DI-PHENYLENE CARBINOL.

FLUORENE CARBOXYLIC ACID

[246°]. Formed by reducing diphenylene ketone carboxylic acid with sodium-amalgam (Fittig a. Liepmann, A. 200, 13). Small crystals (from alcohol). May be sublimed. Sl. sol. boiling water, v. sol. hot alcohol. Gives fluorene when distilled with lime. Alkaline permanganate oxidises it to diphenylene ketone carboxylic acid.

Salts.—BaA', 3aq: glittering scales, sl. sol. water.—CaA', 2½aq: hard white needles.

Ethyl ether EtA'. [54°]. Colourless prisms, v. sol. hot alcohol.

Fluorene carboxylic acid

Methyl ether MeA'. [64°].

Fluorene-di-carboxylic acid C<sub>16</sub>H<sub>8</sub>(CO<sub>2</sub>H)<sub>2</sub>. Formed by reduction of diphenylene-ketone-di-carboxylic acid with sodium-amalgam in the cold, sl. sol. alcohol, ether, and HOAc. On distillation with lime it gives fluorene (Bamberger a. Hooker, B. 18, 1036; A. 229, 161).—Δ<sub>g</sub>2A".

FLUORESCÉIC ACID C<sub>20</sub>H<sub>12</sub>O<sub>4</sub> i.e.

CO<sub>2</sub>H.C<sub>6</sub>H<sub>4</sub>.C(OH) < C<sub>6</sub>H<sub>4</sub>(OH) > O. Fluorescein may be looked upon as the anhydride of this acid; but the acid itself is not known in the free state. Its tetra-bromo-derivative C<sub>20</sub>H<sub>4</sub>Br<sub>4</sub>O<sub>4</sub> is a reddish-yellow pp., obtained by acidifying the product of the action of conc. aqueous KOH upon eosin. Its di-nitro-derivative is obtained in like manner from di-nitro-fluorescein, and forms red crystals (from alcohol).

FLUORESCÉIN C<sub>20</sub>H<sub>12</sub>O<sub>4</sub> i.e.

CO < C<sub>6</sub>H<sub>4</sub>(OH) > O < C<sub>6</sub>H<sub>4</sub>(OH) > O [1:4:6]. Anhydride of tetra-oxy-di-phenyl-phthalide. Anhydride of tetra-oxy-tri-phenyl-carbinol carboxylic acid. Mol. w. 332. Formed by heating phthalic anhydride (5 pts.) with resorcin (7 pts.) at 200°, until the mass gets viscid; the product is boiled with water, washed with alcohol, dissolved in aqueous alkali, and ppd. as a yellow powder by an acid (Baeyer, B. 4, 658; A. 183, 1). According to Mulhäuser (D. P. J. 263, 49) phthalic anhydride (1½ kilos.) is added with stirring to melted resorcin (25 kilos.), and after heating for 1½ hours at 180° the reaction begins, and lasts for 40 minutes. Resorcin and di-oxy-toluene C<sub>6</sub>H<sub>4</sub>(OH).Me[1:3:4] give with phthalic anhydride fluorescent derivatives, while orcin, C<sub>6</sub>H<sub>4</sub>(OH).Me[1:3:5] does not. Hence, to form a

fluorescent body the phthalic acid residue must probably go into the position 5.

Properties.—Dark-red prisms (from alcohol). Sl. sol. hot water, more sol. dilute acids. When freshly ppd. it is v. sol. alcohol and ether, but in the crystallised state it dissolves only on boiling. V. sol. hot HOAc, nearly insol. benzene and chloroform. The ethereal solution is pale-yellow, and not fluorescent; the alcoholic solution exhibits green fluorescence. Fluorescein dissolves readily in aqueous alkalis, the solution exhibiting when dilute a splendid yellowish-green fluorescence. It also dissolves in alkaline carbonates, baryta, and lime-water. Fluorescein begins to decompose at 290°. It dyes silk and wool yellow; but it has little tinctorial value, although it is the starting-point for the eosin colouring matters, which are derived from it by displacement of hydrogen by Br, I, NO<sub>2</sub>, &c. On adding alcoholic NH<sub>3</sub> to an ethereal solution of fluorescein a reddish-yellow pp. is formed, which, however, loses NH<sub>3</sub> on drying.

Reactions.—1. Boiling with aqueous NaOH and zinc-dust decolourises it. On adding an acid and shaking with ether fluorescein C<sub>20</sub>H<sub>12</sub>O<sub>4</sub>, or CO<sub>2</sub>H.C<sub>6</sub>H<sub>4</sub>.CH < C<sub>6</sub>H<sub>4</sub>(OH) > O, is dissolved; on evaporation it is left as a varnish. Its alkaline solution is readily reoxidised to fluorescein.—2. Fusion with caustic NaOH forms resorcin and the acid C<sub>16</sub>H<sub>8</sub>O<sub>4</sub> or CO<sub>2</sub>H.C<sub>6</sub>H<sub>4</sub>.CO.C<sub>6</sub>H<sub>4</sub>(OH), [200°], which on further fusion splits up into CO<sub>2</sub>, resorcin, and benzoic acid.—3. Conc. H<sub>2</sub>SO<sub>4</sub> forms a compound C<sub>20</sub>H<sub>12</sub>O<sub>4</sub>SO<sub>4</sub> [140°–150°], which is resolved by warm water into its components.—4. Boiling with H<sub>2</sub>SO<sub>4</sub> for some time forms resorcin-corulin, which is ppd. by water in dark-red flakes, and dissolves in alkalis, forming a greenish-blue solution.—5. Bromine, in HOAc, forms di-bromo-fluorescein C<sub>20</sub>H<sub>8</sub>Br<sub>2</sub>O<sub>4</sub> [260°–270°] and eosin C<sub>20</sub>H<sub>6</sub>Br<sub>2</sub>O<sub>4</sub>.—6. Aqueous NH<sub>3</sub> when heated with it for 8 hours forms thick orange monoclinic prisms and tables of C<sub>20</sub>H<sub>13</sub>N<sub>2</sub>O<sub>4</sub>, which is a direct yellow dye for wool.

It is probably C(NH) < C<sub>6</sub>H<sub>4</sub> > C < C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>) > O

(R. Meyer a. Oppelt, B. 21, 3376).

Metallic derivatives CaC<sub>20</sub>H<sub>10</sub>O<sub>4</sub>4aq. Obtained by boiling fluorescein with water and CaCO<sub>3</sub> (Schreder, B. 11, 1342). Slender reddish-brown needles with green lustre.—BaC<sub>20</sub>H<sub>10</sub>O<sub>4</sub> 9aq: crimson plates.

Acetyl derivative C<sub>20</sub>H<sub>10</sub>Ac<sub>2</sub>O<sub>4</sub>. [300°]. Needles (from alcohol-acetic acid). Sl. sol. alcohol, v. sol. HOAc, insol. ether, benzene, and chloroform.

Benzoyl derivative C<sub>20</sub>H<sub>10</sub>Bz<sub>2</sub>O<sub>4</sub>. [215°]. Crystals (from acetone); sl. sol. alcohol and ether.

Ethyl derivative C<sub>20</sub>H<sub>14</sub>EtO<sub>4</sub>. [156°]. From fluorescein, KOH, and alcoholic EtBr at 120°. Pale-yellow needles (from ether); v. sol. alcohol, chloroform, and benzene; insol. dilute alkalis.

Di-ethyl derivative C<sub>20</sub>H<sub>16</sub>Et<sub>2</sub>O<sub>4</sub>. Not formed by the action of EtBr on potassium fluorescein, but sparingly formed by the action of EtI on the silver derivative. Pale-yellow plates (from alcohol); sl. sol. ether and alcohol; the alcoholic solution shows a vivid yellow fluorescence. Not dissolved by dilute alkalis, but splits

up into alcohol and fluorescein by conc. KOH aq. or  $H_2SO_4$ .

*Chloride*  $C_{20}H_{11}O_4Cl_2$  [252°]. From fluorescein (1 mol.) and  $PCl_5$  (2 mols.) at 100°. Prisms (from toluene-alcohol). V. sol. hot benzene and toluene, sl. sol. alcohol and ether. Not affected by aqueous or alcoholic KOH, but destroyed by potash-fusion. Water and slaked lime at 280° reconvert it into fluorescein. Reduced in alcoholic solution by NaOH and zinc-dust to  $C_{20}H_{13}Cl_2O_4$  [226°]. Sol. alcohol, benzene, ether, and acetone (Drewsen, A. 212, 351). Fuming HIAq at 150° gives  $C_{20}H_{11}O_4I_2$ , which crystallises from alcohol in plates [230°]. Sol. dilute, but insol. conc., KOH aq.

*References*.—DI-BROMO-, DI-BROMO-DI-NITRO-, CHLORO-, DI-CHLORO-TETRA-IODO-, and NITRO-FLUORESCIN.

*Homofluorescein* (so-called)  $C_{20}H_{11}O_4$ . Prepared by the action of chloroform and NaOH on orcin (Schwarz, B. 13, 543). Red, metallic-green needles or plates. Sl. sol. water, alcohol, and cold acetic acid, insol. ether, benzene, and ligroin. Its dilute alkaline solutions have a strong green fluorescence. It is a weak dibasic acid. The sodium salt forms fine yellowish-red needles, sol. water; the barium salt red needles or scales, and the silver salt a dark-red powder. Its substitution-products dye wool and silk various shades of yellow and red.

*Tetra-acetyl derivative*  $C_{24}H_{17}O_8$  (OAc)<sub>4</sub> + 2H<sub>2</sub>O? Amorphous powder or brownish-yellow plates. Insol. water, sol. alcohol.

*Tetra-bromo-homo-fluorescein*  $C_{20}H_5Br_4O_4$ . Brown leaflets. Sol. alcohol.— $NaC_{20}H_5Br_4O_4$  4aq; microscopic red needles, sol. NaOH aq.

*Tri-iodo-homofluorescein*  $C_{20}H_5I_3O_4$ . Microscopic red crystals.— $NaC_{20}H_5I_3O_4$ . Red microscopic needles, sol. hot water and dilute alcohol, insol. NaOH aq.

*Hexa-nitro-oxy-homofluorescein*  $C_{20}H_5(NO_2)_6O_4$  aq. Reddish-yellow leaflets. Formed by nitration of homofluorescein. By boiling with aqueous  $NH_3$  it forms the acid  $C_{20}H_5N_6O_{10}$ , and by the action of KCN the acid  $C_{20}H_5N_6O_{11}$ . The nitrate is a yellowish-red crystalline powder, explodes at 180°, sol. alcohol.— $A^+Na$  and  $A^+Ag$ . Small red leaflets.

*Hexa-amido-oxy-homofluorescein*  $C_{20}H_5(NH_2)_6O_4$ . Colourless microscopic crystals. Produced by reduction of the hexa-nitro-compound.

*Hexa-nitro-homofluorescein-cyamido acid*  $C_{20}H_5N_6O_{11}$  aq. Crystalline powder. Sparingly sol. water and alcohol. Formed by the action of KCN on the hexa-nitro-compound.— $A^+K$ . Fine yellow soluble needles.

Compound  $C_{20}H_5N_6O_{10}$ . Reddish-yellow powder. Formed by boiling the nitrate of the hexa-nitro-compound with aqueous  $NH_3$ .— $A^+(NH_4)$ . Reddish-yellow scales or small yellow needles (Schwarz, B. 13, 543).

FLUORESCIN CARBOXYLIC ACID

Prepared by heating resorcin with trimellitic anhydride (Schredax, B. 11, 1340). Yellow amorphous powder; v. sl. sol. water and HOAc, v. sol. alcohol, ether, and benzene. The metal-

lic derivatives  $Ba_2A'''$ , and  $Ca_2A'''$ , are red amorphous powders.

*Acetyl derivative*  $C_{22}H_{13}Ac_2O_4$ ; yellow flocculi.

*Di-bromo-derivative*  $C_{20}H_5Br_2O_4$ ; red needles.

*Tetra-bromo-derivative*  $C_{20}H_5Br_4O_4$ , red amorphous powder.— $K_2C_{20}H_5Br_4O_4$ .

**FLUORESCIN-SULPHONIC ACID**  $C_{20}H_7O_5(SO_3H)$ . Reddish-yellow needles or prisms. Easily soluble in alcohol and hot water less readily in cold water, insoluble in ether. Its aqueous solution is yellow, with a slight fluorescence; the alkaline solution possesses a powerful green fluorescence. Obtained by heating (8)-sulphophthalic acid with resorcin.— $A'''Ca$ . Res. solid, very soluble in alcohol (Graebe, B. 18 1129).

**FLUORHYDRIC ACID**. HF. (*Hydrofluoric acid. Hydrogen fluoride*). Mol. w. 20. [−92.3° (Olszewski, M. 7, 371). (19.44°) (Gore, Pr. 17 256). S.G.  $\frac{1.177}{1.175}$  9879 (Gore, Lc.). V.D. c. 10 a 100° (Gore, Fr. 1869. 173); 19.6 at 30.5° (Mallet Am. 3, 189); 25.6 at 26.4°; 10.3 at 88.8° (Thorpe a. Hambly, C. J. Trans. 1888. 765; 1889. 163) Vapour pressure at 15° = 394 mm. (Gore).

Schwankhardt observed in 1670 that glass could be etched by fluorspar and sulphuric acid. Scheele, in 1771, recognised that this etching was due to the formation of an acid from the fluorspar; Wenzel prepared the acid fairly pure. Gay-Lussac and Thénard, in 1810, examined its properties; and Ampère suggested that the acid was not an oxygen compound. Gore, in 1868 obtained the pure acid.

*Formation*.—1. By decomposing calcium fluoride (*fluorspar*) by sulphuric acid.—2. By heating acid potassium fluoride,  $KHF_2$ .—3. By the reaction of dry  $H_2S$  with  $PbF_2$ .—4. By heating AgF in a stream of H.

*Preparation*.—1. 200 grams dry KHF<sub>2</sub> are heated in a Pt retort so long as moisture comes off; the neck of the retort is then connected with a small condenser made of Pt, the joint being made tight by molten sulphur; this condenser is filled with a freezing mixture, more of which can be supplied by a specially arranged charging apparatus; the condenser ends in a small Pt flask, from the neck of which a long Pt tube passes upwards. On continued heating the KHF<sub>2</sub> is decomposed to KF + HF; the HF is condensed and received in the Pt flask; the air in the apparatus escapes through the Pt tube, the length of which prevents the entrance of moisture. The figure shows the arrangement.—2. Approximately

pure liquid HF may be prepared by gently heating a mixture of pure conc.  $H_2SO_4$  with so much powdered CaF<sub>2</sub> (free from silica) that the whole

remains quite liquid, in a Pt retort connected with a small Pt flask or U tube surrounded by a freezing mixture.—8. An aqueous solution of HF is prepared by heating together powdered  $\text{CaF}_2$  and conc.  $\text{H}_2\text{SO}_4$  in a leaden retort, and leading the gas into water in a vessel of Pt or Pb kept cold by ice (for description of the apparatus *v. Briegleb, A. 111, 880*). Commercial HFAq may be purified by passing  $\text{H}_2\text{S}$  into it, adding enough  $\text{K}_2\text{CO}_3$  to saturate the  $\text{H}_2\text{SO}_4$  and  $\text{H}_2\text{SiF}_6$  present, decanting from the pp., removing  $\text{H}_2\text{S}$  by  $\text{AgCO}_3$ , filtering and distilling from a retort of Pb or Pt (*Gore, Lc.*). The aqueous acid is kept in bottles made of gutta percha.

**Properties.**—A colourless, very mobile liquid, which fumes in the air and absorbs water very rapidly. Burns and inflames if let fall on the skin. The vapour is very irritating and very poisonous. The anhydrous acid should be kept in Pt flasks with tight-fitting Pt caps covered with paraffin. Solidifies at  $-102.5^\circ$  and liquefies again at  $-92.3^\circ$  (*Olszewski, M. 7, 371*). A conc. aqueous solution of HF is a colourless, strongly acid liquid, which fumes in the air; when distilled at 760 mm. HF is evolved and a liquid remains, containing 36.38 p.c. HF; when this acid is kept in contact with chalk for a little the liquid then contains 32.5–32.7 p.c. HF; when dilute HFAq is distilled at 760 mm. water is evolved until the liquid contains 32.2–32.4 p.c. HF, when the composition remains constant (*Roscoe, C. J. 13, 162*). S.G. of HFAq 85° p.c. HF = 1.15; S.G. of most conc. HFAq = 1.06. Bineau regarded the acid of 85.9 p.c. as a hydrate  $\text{HF} \cdot 2\text{H}_2\text{O}$ , but *Roscoe's* observations, which show that composition varies with pressure, render the existence of a definite hydrate improbable. When HFAq is neutralised by soda much heat is produced; [ $\text{HFAq} \cdot \text{NaOH} \cdot \text{aq} = 16,272$  (*Th. 1, 167*). Addition of HFAq to the NaF thus formed causes disappearance of heat ( $\text{NaFAq} \cdot \text{HFAq} = -288$  (*Thomsen*). The heat of neutralisation of HFAq is 18 to 19 p.c. greater than that of the analogous haloid acids; HF is the only haloid acid the reaction of which with its own alkali salts is attended by the disappearance of a considerable quantity of heat. The relative affinity of HFAq is extremely small, being less than 1 if that of  $\text{HCl} \cdot \text{aq}$  is taken as 100 (*cf. AFFINITY, vol. i. p. 75*).

**Molecular weight.**—If HF is the molecular formula of fluorhydric acid the vapour density of the compound must be 10 ( $\text{H} = 1$ ); *Gore* determined the V.D. indirectly by heating a known volume of H with a slight excess of  $\text{AgF}$  and measuring the HF produced; at  $100^\circ$  the volume of HF was approximately double that of the H, but at lower temperatures it was considerably less (*Tr. 1869, 173*). *Mallet* weighed the HF gas in a flask coated internally with paraffin; at  $80.5^\circ$  the V.D. was found to be 19.6, which corresponds fairly well with the formula  $\text{H}_2\text{F}_2$  (*Am. 8, 189*). *Thorpe* and *Hamblly* (*C. J. Trans. 1888, 765; 1889, 163*) have determined the V.D. of HF in a specially constructed apparatus of Pt; they made 14 experiments at temperatures between  $26.4^\circ$  and  $88.8^\circ$ ; the V.D. varied from 26.6 at  $26.4^\circ$  to 10.8 at  $88.8^\circ$ ; these results rather point to the gradual breaking down of a complex molecular group as temperature rises, with final production of molecules of HF, than to the exist-

ence of definite molecules of  $\text{H}_2\text{F}_2$  at one temperature and HF at another. They have also examined the effect of altering pressure, at constant temperature, on the V.D. of HF. The temperature chosen was  $32^\circ$ , because the V.D. at this temperature and 760 mm. pressure corresponds with the formula  $\text{H}_2\text{F}_2$ . A small lowering of pressure was accompanied by considerable decrease of V.D.; hence there is no evidence of the existence of a stable gaseous molecule  $\text{H}_2\text{F}_2$ . Nevertheless the results do not negative the view that the composition of the chemically-reacting unit of fluorhydric acid is represented by the formula  $\text{H}_2\text{F}_2$ . This view is in keeping with the readiness with which fluorides such as  $\text{KFHF}$  (=  $\text{KHF}_2$ ) are produced (*v. FLUORIDES*). But it might be argued that the existence of the salts  $\text{KF} \cdot 2\text{HF}$  and  $\text{KF} \cdot 3\text{HF}$  (*Moissan, C. R. 106, 647*) points to the existence of the acids  $\text{H}_2\text{F}_2$  and  $\text{H}_3\text{F}_4$ .

**Reactions.**—1. When dilute HFAq is electrolysed in a Pt vessel, H and O (with ozone) only are evolved; if the solution contains 80 p.c. HF the acid is decomposed, H is evolved at the kathode, and the anode is attacked by the F there produced (*Gore, Pr. 17, 266*). Electrolysis of liquid HF kept at  $-23^\circ$  results in production of fluorine at the anode (*Moissan, C. R. 103, 202, 256*); for details of apparatus, &c. *v. FLUORINE, p. 461*.—2. Liquid hydrofluoric acid at  $-29^\circ$  to  $-18^\circ$  does not react with non-metals, nor with metals except the alkali metals; it reacts violently with many anhydrides, *e.g.*  $\text{P}_2\text{O}_5$ ,  $\text{SO}_3$ ; chlorides of alkali and alkaline earth metals are decomposed, also chlorides of phosphorus, antimony, and titanium; many organic bodies are rapidly charred; paraffin is unchanged; glass is unattacked by perfectly dry liquid HF, but if a trace of moisture is present  $\text{SiF}_4$  is formed (for other similar observations *v. Gore, Pr. 17, 266; Tr. 1869, 173*).—3. An aqueous solution of hydrofluoric acid reacts with metals and metallic oxides very similarly to  $\text{HCl} \cdot \text{aq}$ , forming fluorides, and evolving H with metals, and forming water with metallic oxides; silicon, boron, tantalum, and zirconium, are dissolved by HFAq.—4. Silica and silicates are rapidly decomposed by HFAq with evolution of gaseous  $\text{SiF}_4$ ; if water is present in considerable quantity the  $\text{SiF}_4$  reacts with it to produce silicofluorhydric acid  $\text{H}_2\text{SiF}_6$  (*v. SILICO-FLUORIDES* under *SILICON*). This reaction is made use of in etching glass.—5. Titanic, tin, tantalic, molybdic, and tungstic oxides, which are insoluble in most acids, are dissolved by HFAq forming fluorides, which then combine with HF (*v. TITANO-FLUORIDES, STANNO-FLUORIDES, &c., under TITANIUM, TIN, &c.*).—6. With metallic oxides HFAq reacts to form fluorides, and in many cases these combine with  $\text{zHF}$  (*v. FLUORIDES*).

**Combinations.**—With many fluorides to form salts, of which  $\text{KF} \cdot \text{HF}$ ,  $\text{NH}_4\text{F} \cdot \text{HF}$ ,  $\text{BiF}_3 \cdot 3\text{HF}$ , and  $\text{SiF}_4 \cdot 2\text{HF}$ , are typical. Certain of these compounds of HF with fluorides are best regarded as distinct acids, *e.g.*  $\text{SiF}_4 \cdot 2\text{HF}$  reacts as an acid forming salts,  $\text{M}^+\text{SiF}_6^-$ , known as silico-fluorides; stannofluorides, tantanofluorides, &c., are also known; these salts are described under their respective headings as sections of the articles *SILICON, TIN, TANTALUM, &c. (v. also FLUORIDES)*.

M. M. P. M.

**FLUORIDES.** *Binary compounds of F with other elements.* Fluorides of all the metals with the exception of 10 or 12 (and these mostly rare metals which have not been at all thoroughly examined) have been prepared. Fluorides of the following non-metals are also known, viz. B, H, I, P, Se, S, and Te; no fluoride of Br, C, Cl, N, or O has yet been isolated. Fluorides are prepared (1) by the reaction between HFAg and metals or metallic oxides; (2) by heating fluorspar and H<sub>2</sub>SO<sub>4</sub> with metallic oxides, this method is applicable to volatile metallic fluorides; (3) by ppn., applicable to insoluble metallic fluorides; (4) by heating non-metals with HgF<sub>2</sub> or PbF<sub>2</sub>. Metallic fluorides are generally easily fusible solids, similar to, and, as a rule, isomorphous with, the chlorides. Some non-metallic fluorides are gaseous at ordinary temperatures, e.g. SiF<sub>4</sub> and PF<sub>5</sub>; others are liquids, e.g. IF<sub>5</sub>; and a few are solids, e.g. SbF<sub>5</sub>. Metallic fluorides are generally insoluble in water; AgF and SnF<sub>2</sub> are soluble, and FeF<sub>2</sub>, NaF, and KF, are sparingly soluble. The fluorides of Bi and Sb are not decomposed by water, whereas the chlorides of these metals are at once decomposed. Most metallic fluorides are very stable, not being decomposed either by heat, or by heating with carbon or in oxygen; solutions of these fluorides generally react slowly with alkaline silicates forming Hf and basic fluorides. Non-metallic fluorides are generally more stable than the corresponding bromides, chlorides, or iodides; thus PCl<sub>5</sub> is dissociated by heat, but PF<sub>5</sub> is an extremely stable gas. Fluorides are decomposed by heating with Cl or with conc. H<sub>2</sub>SO<sub>4</sub>. Almost all metallic fluorides readily combine with HF forming acid salts, aqueous solutions of which turn blue litmus red and etch glass; these acid salts are decomposed by heat with evolution of HF. Some of these acid salts are better regarded as distinct acids, the negative radicle of which is formed of metal and fluorine; the following probably belong to this class: SnF<sub>2</sub>·2HF, TiF<sub>2</sub>·2HF, ZnF<sub>2</sub>·2HF; (=H<sub>2</sub>MF<sub>2</sub>). Fluorides, as a class, combine together to form double fluorides; the fluorides of the alkali metals show a remarkable readiness to combine with other metallic fluorides; in many cases, but not in all, as many molecules of alkali fluoride combine, as there are atoms of fluorine in the other fluoride, e.g. BeF<sub>2</sub>·2NaF, BiF<sub>3</sub>·3KF. These double fluorides are generally more stable compounds than corresponding double chlorides, bromides, or iodides. The readiness with which acid fluorides and double fluorides are produced has suggested that the formula expressing the composition of what may be called the *chemical molecule* of fluorhydric acid should be written H<sub>2</sub>F<sub>2</sub>. This is perhaps confirmed by the especial ease with which alkali fluorides form acid fluorides MHF<sub>2</sub>; thus KF and NaF react with an acid so weak as acetic to form KHF<sub>2</sub> and NaHF<sub>2</sub>, respectively (2KFAg + C<sub>2</sub>H<sub>3</sub>O<sub>2</sub>Ag = KF.HFAg + C<sub>2</sub>H<sub>3</sub>KO<sub>2</sub>Ag). The fact that the quantity of heat which disappears when HFAg reacts with NaF amounts to about 2 p.c. of the heat of neutralisation of HF by NaOH, whereas when the other haloid acids react with their alkali salts hardly any heat disappears, tends to confirm the view that the reacting unit of fluorhydric acid is H<sub>2</sub>F<sub>2</sub>, rather than HF. The very small affinity of HFAg (less than 1 when

that of HClAg = 200), especially when in conjunction with the marked stability of the fluorides, also marks off this acid from the other haloid acids.

*Fluorides are detected* by gently heating with conc. H<sub>2</sub>SO<sub>4</sub> in a leaden or platinum vessel which is covered with a piece of glass coat with wax, through which lines are traced with needle; after a little the glass is removed as the wax wiped off when warm; the glass appears etched where it was exposed to the vapour HF coming from the fluoride. Fluorides may also be detected by mixing with microcosm salt and heating strongly by a small blowpipe flame in a glass tube open at both ends; HF evolved and partially condenses with water in the upper parts of the tube; on evaporating the water a dull spot is seen on the glass.

*Fluorides are estimated* by evaporation with conc. H<sub>2</sub>SO<sub>4</sub>, the residual metallic sulphate weighed, and the fluorine is determined by difference. Or the issuing vapour is led into water a weighed quantity of PbO is added, the whole is evaporated to dryness and heated, and the residue is weighed; in this process F is substituted for O; if  $d =$  increase in the weight of the oxide of lead used, then

$$\text{amount of F in residue} = \frac{19}{19-8}d.$$

For details, and also for other methods of estimating F and HF in presence of fluorides, a for separation of F from other elements, a manual of analysis must be consulted. M. M. P. M.

**FLUORINE.** F. At. w. 19. Mol. w. (Moissan, C. R. 109, 861). For chief lines emission-spectrum, v. Salet (A. Ch. [4] 28, 8 and Moissan (C. R. 109, 937).

*History.*—Schwankhardt, in Nürnberg, observed in 1670 that glass is etched by contact with sulphuric acid and fluorspar. About 1 year after this, Scheele showed that the etching observed by Schwankhardt was due to a distinctive acid produced by the reaction between fluorspar and sulphuric acid. Gay-Lussac and Thénard obtained this acid in 1808 (A. Ch. [2] 204), and endeavoured, unsuccessfully, to demonstrate the presence of oxygen in it. In 1816 Ampère declared the acid to be analogous to hydrochloric acid, and to be a compound of H with an element resembling chlorine. To this element he gave the name of *Phlor* (φθλός = destroying), but the name *fluorine* was generally employed inasmuch as it suggested that the etching compound of the element was obtained from fluorspar (*Spatum fluoricum*). The investigations of Fremy (A. Ch. [3] 47, 6) and Gore (Pr. 17, 25 Tr. 1869, 173) rendered certain the composition of the acid first obtained by Gay-Lussac and Thénard. Davy, in 1809 and 1813 (Tr. 1809; 1826) endeavoured to isolate fluorine by leading Cl over heated AgF; as he obtained a gas which seemed to be O he concluded that F had probably been liberated, but had reacted with the glass. He then used Pt vessels, but obtained fluorine of Pt; a trial with vessels of fluorspar was successful. Baudrimont (J. pr. 7, 447) has a mixture of fluorspar, MnO<sub>2</sub>, and H<sub>2</sub>SO<sub>4</sub> in a glass vessel, and obtained what he declared to be a mixture of HF, SiF<sub>4</sub>, and F; he described F as a yellowish gas which bleached, did not

on glass, and combined with gold; the gas was probably Cl derived from chlorides in the fluorspar used. Knox attempted to decompose HgF by Cl in a vessel of fluorspar (*J. pr.* 9, 118); he obtained HgCl and a yellowish gas which rapidly acted on glass. S. J. Knox electrolyzed HF and  $\text{PbF}_2$ , and obtained a colourless gas, which did not act on Au or Pt (*J. pr.* 20, 172). Louyet (*Ph. C.* 1847, 321) again attempted to decompose HgF by Cl, using a vessel of fluorspar. He obtained a colourless gas which did not attack glass, decomposed water at the ordinary temperature, and combined directly with all metals except Au and Pt. Kämmerer (*J. pr.* 85, 457) allowed I to react with AgF in a vacuum glass tube at  $70^\circ\text{--}80^\circ$ ; he obtained a colourless gas, which was wholly absorbed by KOH, but did not combine with Hg. Phipson (*J. pr.* 88, 63) thought he had isolated F by the reaction between  $\text{CaF}_2$ ,  $\text{KMnO}_4$ , and  $\text{H}_2\text{SO}_4$ ; he described it as a colourless gas, which bleached, decomposed water rapidly, and was without action on glass. Prat (*C. R.* 64, 845, 511) decomposed KF by heating with  $\text{MnO}_2$  and  $\text{KNO}_3$ ; he treated the gas obtained with baryta, and described the residual gas as F; it was colourless, combined with most metals, also with B and Si, but not with  $\text{SiO}_2$ . Gillis repeated Prat's experiments, but obtained only O (*Z.* [2] 4, 660). Renisch (*N. J. P.* 12, 1) obtained what he regarded as a mixture of O and F by heating cryolite with  $\text{PbO}_2$  and  $\text{K}_2\text{S}_2\text{O}_8$ . Gore attempted to prepare F by decomposing AgF by Cl (*C. J.* [2] 7, 368). Varenne noticed the production of a gas which attacked Pt by heating  $(\text{NH}_4)_2\text{Cr}_2\text{O}_7$  with HF (*C. R.* 91, 989). O. Löw (*B.* 14, 1144, 2440) thought that the greenish gas obtained by breaking up fluorspar from Wösendorf was F; he traced the F to the presence of a fluoride of Ca, which was decomposed with evolution of F. Brauner in 1881 (*B.* 14, 1944) obtained a gas more or less resembling Cl by heating  $\text{CeF}_3$ , and also by heating  $\text{PbF}_2$ . In 1886 Moissan electrolysed dry liquid HF in a Pt tube by means of a powerful battery (*C. R.* 102, 1543); H was obtained at the negative pole, and at the positive pole a gas was formed which decomposed water with production of ozone, and was wholly absorbed by Hg with formation of  $\text{HgF}_2$ ; the gas combined energetically with P and Si. A little later (*C. R.* 103, 202, 256) Moissan repeated the electrolysis of HF and obtained F.

**Preparation.**—The apparatus used by Moissan consists of a U-tube of Pt, with stopper of fluorspar and Pt delivery tubes; the positive electrode is formed of an alloy of Pt with 10 p.c. of Ir;  $\text{KHF}_4$  is dried at  $100^\circ$ , and then *in vacuo* over  $\text{H}_2\text{SO}_4$  and KOH; the salt is then heated in a Pt retort, and the HF is condensed in a Pt receiver surrounded by a freezing mixture. The HF is placed in the U-tube which is surrounded by  $\text{CH}_2\text{Cl}_2$  boiling at  $-23^\circ$ ; the current from 20 Bunsen cells, coupled in series, is passed through the liquid; any traces of water in the HF are decomposed with formation of gases at the positive pole; when the HF is perfectly dry electrolysis stops, a little perfectly dry  $\text{KHF}_4$  is dissolved in the HF, and the conductivity is thus increased. H is now evolved at the negative pole, while at the positive pole there is produced a colourless gas in which Si, B, As, Sb, S, and I Vol. II.

take fire, and which decomposes  $\text{H}_2\text{O}$ , forming HF and ozone, and possesses other distinctive properties quite different from those belonging to a mixture of HF and ozone (*v. Properties and Reactions*).

To determine whether this gas was really F or a perfluoride of H, Moissan connected the electrolytic apparatus with a Pt tube containing KF, to remove traces of HF, and then connected this tube with another made of Pt containing a weighed quantity of iron wire, and attached to an apparatus for collecting any gas which might come from the tube. The whole apparatus was filled with dry  $\text{CO}_2$ , and an arrangement was adopted for collecting and measuring the H evolved at the negative pole. The tube containing the iron wire was heated to dull redness, the U-tube was cooled to  $-50^\circ$ , and electrolysis was begun. The weight of iron fluoride formed was exactly equivalent to that of H evolved; no gas, except a trace of air, was obtained from the tube in which the iron wire was heated. Hence the gas evolved at the positive pole was fluorine. Moissan says that as much as 1.5–2 litres F can be obtained in an hour by this method. He also states that the gas is formed by electrolysis of fused  $\text{KHF}_4$ .

**Properties and Reactions.**—Fluorine is a pale yellow-green gas. It decomposes water, forming ozone and HF. Crystallised silicon, boron, arsenic, antimony, sulphur, and iodine, take fire at once in the gas. It attacks metals less readily, probably because a film of fluoride is soon formed on the surface. Powdered iron and manganese burn brilliantly in F, when gently heated. Organic compounds are rapidly decomposed, alcohol, ether, benzene, &c., take fire at once in the gas. F combines violently with hydrogen even in the dark.

Fluorine is allied to Cl, Br, and I; the analogy is shown in the composition and properties of its compounds, but there are points of difference (*v. FLUORHYDRIC ACID and FLUORIDES*).

The atomic weight of fluorine has been determined (1) from determination of V.D., and analyses, of HF (Gore, *Pr.* 17, 256; *Tr.* 1869, 173; Mallet, *Am.* 3, 189; Thorpe & Hambly, *C. J. Trans.* 1888, 765; 1889, 163); (2) by converting  $\text{CaF}_2$  into  $\text{CaSO}_4$  (Louyet, *A. Ch.* [3] 26, 295; Dumas, *A. Ch.* [3] 55, 170; De Luca, *C. R.* 51, 299); (3) by converting NaF to  $\text{Na}_2\text{SO}_4$ , KF to  $\text{K}_2\text{SO}_4$ , and  $\text{PbF}_2$  to  $\text{PbSO}_4$  (Louyet, *l.c.*; Dumas, *l.c.*); (4) by treating  $\text{Mn.F.4NH.F}$  with HCl and KI, and estimating the I set free by titration with  $\text{Na}_2\text{S}_2\text{O}_8$  (Christensen, *J. pr.* [2] 84, 41). M. M. P. M.

*m*-FLUORO-ANILINE  $\text{C}_6\text{H}_4\text{F.NH}_2$  (1.3). From  $\text{C}_6\text{H}_5(\text{NHAc}).\text{N}_3\text{NC}_6\text{H}_5$ , and conc. HF (Wallach, 4, 235, 266). Oil. — ( $\text{B'HCl}$ ),  $\text{PtCl}_2$ .

*p*-Fluoro-aniline  $\text{C}_6\text{H}_4\text{F.NH}_2$  (1.4). (*p.* 189°). S.G.  $\frac{25}{4}$  1.153. From *p*-fluoro-nitro-benzene,  $\text{SnCl}_2$ , and HCl (Wallach, 4, 336, 367). Liquid which solidifies in a bath of ether solid and 40°.

**Salts.**— $\text{B'HCl}$ . — ( $\text{B'HCl}$ ),  $\text{PtCl}_2$ .

*Acetyl derivative*  $\text{C}_6\text{H}_4\text{F.NHAc}$ . [151°].

Sl. sol. water (Wallach & Heuser, 4, 243, 223).

FLUORO-BENZENE  $\text{C}_6\text{H}_5\text{F}$ . Mol. w. 96. (85°). S.G.  $\frac{25}{4}$  1.0236.  $\mu_2$  1.48773 (Wallach & Heuser, 4, 243, 219). V.D. 3.15 (calc. 3.06).

**Formation.**—1. By heating potassium

Q Q

fluoro-benzene sulphamate with conc.  $\text{HClAq}$  (Paternò a. Oliveri, G. 13, 538).—2. By decomposing diazobenzene piperidine with conc. aqueous hydrofluoric acid, the escaping gases being very well cooled (Wallach, A. 235, 255).

**Properties.**—Liquid which solidifies in ether and solid carbonic acid. The so-called fluoro-benzene described by Schmitt a. Gehren (*J. pr.* [2] 1, 394) was phenol.

*p*-Di-fluoro-benzene  $\text{C}_6\text{H}_4\text{F}_2$  [1.4]. (88°). S.G. 1.11. Formed by decomposing *p*-fluoro-benzene diazo-piperidine with hydrofluoric acid (Wallach a. Heusler, A. 243, 224). Liquid solidifies at a very low temperature.

***p*-FLUORO-BENZENE SULPHONIC ACID**  $\text{C}_6\text{H}_4\text{F.SO}_3\text{H}$  [1.4]. From *p*-amido-benzene sulphonic acid by displacing  $\text{NH}_2$  by F (Lenz, B. 10, 1187; 12, 580). The salts are v. e. sol. water and alcohol.

**Chloride**  $\text{C}_6\text{H}_4\text{F.SO}_2\text{Cl}$  [36°]. Trimetric tables or long needles; v. sol. benzene, chloroform, and ether.

**Amide**  $\text{C}_6\text{H}_4\text{F.SO}_2\text{NH}_2$  [123°]. Trimetric plates or long needles. Sl. sol. water and benzene, v. sol. acetone and alcohol.

***o*-FLUORO-BENZOIC ACID**  $\text{C}_6\text{H}_3\text{F.CO}_2\text{H}$  [1.2]. Mol. w. 140. [118°]. Prepared by treating *o*-diazido-amido-benzoic acid with conc.  $\text{HFAq}$   $\text{NH}_2\text{C}_6\text{H}_3(\text{CO}_2\text{H})\text{N}_2\text{C}_6\text{H}_3\text{CO}_2\text{H} + 2\text{HF} = \text{C}_6\text{H}_3(\text{NH}_2\text{F})\text{CO}_2\text{H} + \text{C}_6\text{H}_3\text{F.CO}_2\text{H}$

(Paternò a. Oliveri, G. 12, 85). Colourless silky needles (from hot water). V. sol. alcohol and ether. More soluble in water than its isomerides.  $\text{BaA'}$ , 2aq: laminae, v. e. sol. water.— $\text{CaA'}$ : laminae, v. e. sol. water.

***m*-Fluoro-benzoic acid**  $\text{C}_6\text{H}_4\text{F.CO}_2\text{H}$  [1.3]. [124°]. From *m*-diazido-amido-benzoic acid and conc. aqueous HF (P. a. O.). Laminae, resembling benzoic acid.— $\text{NaA'}$  aq: opaque scales.— $\text{AgA'}$ : colourless needles (from hot water); quickly altered by exposure.— $\text{BaA'}$ , 8aq: v. sol. hot water.— $\text{CaA'}$ , 8aq: pearly plates.

**Methyl ether**  $\text{MeA'}$ . (194°). Aromatic oil.

***p*-Fluoro-benzoic acid**  $\text{C}_6\text{H}_3\text{F.CO}_2\text{H}$  [1.4]. [183°]. Prepared by heating *p*-diazido-amido-benzoic acid with concentrated aqueous hydrofluoric acid; on cooling, the greater part of the fluoro-benzoic acid separates out, while the hydrofluoride of *p*-amido-benzoic acid [211°] remains in solution (Schmitt a. Gehren, *J. pr.* [2] 1, 394; Paternò, G. 11, 90; 12, 85). Obtained also by oxidation of *p*-fluoro-toluene (Wallach, A. 235, 263). Laminae or needles, smelling like benzoic acid, sl. sol. cold, v. sol. hot, water; v. sol. alcohol, ether, and benzene. Volatile with steam. Does not etch glass. Conc.  $\text{HNO}_3$  gives a fluoro-nitro-benzoic acid. Conc.  $\text{H}_2\text{SO}_4$  dissolves it without alteration.

**Salts.**— $\text{BaA'}$ , 4aq: colourless ill-defined laminae, m. sol. hot water.— $\text{CaA'}$ , 8aq: large prisms.— $\text{AgA'}$ : yellow plates (from water).

**Ethyl ether**  $\text{EtA'}$ : crystalline; may be distilled.

**Di-fluoro-benzoic acid**  $\text{C}_6\text{H}_2\text{F}_2\text{CO}_2\text{H}$  [232°]. Formed by the action of chromium perfluoride (from  $\text{CaF}_2$ ,  $\text{K}_2\text{Cr}_2\text{O}_7$ , and  $\text{H}_2\text{SO}_4$ ) upon benzoic acid (Jackson a. Hartshorn, B. 18, 1993; *Am.* 7, 848). Flat white needles, sl. hot benzene, sl. sol. hot water, nearly insol. cold water.

**Salts.**— $\text{A'}$ , Ca 8aq: long silky needles. S. 5 at 15°.— $\text{A'}$ , Ba: scales. S. 1.2 at 15°.— $\text{KA'}$ .

***p*-FLUORO-BROMO-BENZENE**  $\text{C}_6\text{H}_3\text{BrF}$  [1.4]. [−15° to −20°]. (153°). S.G. 1.593. From *p*-fluoro-aniline by diazotisation and treatment with cuprous bromide (Wallach a. Heusler, A. 243, 226). Oil.

***p*-FLUORO-CHLORO-BENZENE**  $\text{C}_6\text{H}_3\text{ClF}$  (131°). S.G. 1.226. From *p*-fluoro-aniline by diazotisation and treatment with cuprous chloride (Wallach a. Heusler, A. 243, 226). Oil; volatile with steam. Solidifies at a very low temperature.

***o*-FLUORO-CINNAMIC ACID**  $\text{C}_9\text{H}_7\text{FO}_2$ , i.e.  $\text{C}_6\text{H}_3\text{F.CH:CH.CO}_2\text{H}$ . From the sulphate of *o*-diazido-cinnamic acid and HF (Griess, B. 18, 961). Long needles. V. sl. sol. boiling water, v. sol. alcohol.

**FLUORO- $\psi$ -CUMENE**  $\text{C}_9\text{H}_8\text{Me}_2\text{F}$  [1.3:4.6]. [27°]. (175°). From diazo- $\psi$ -cumene piperidine and conc.  $\text{HFAq}$  (Wallach a. Heusler, A. 243, 231). Volatile with steam.

**FLUORO-HIPPURIC ACIDS**  $\text{C}_9\text{H}_7\text{F.CO.NH.CH}_2\text{CO}_2\text{H}$ . The fluoro-benzoic acids are transformed by the animal organisms into the corresponding fluoro-hippuric acids, and may be extracted from the urine by evaporating it to a syrup, treating with alcohol and filtering. The residue, on distillation of the alcohol, is decomposed with hydrochloric acid and taken up with ether, which on distillation leaves an oily mass from which the pure acid is obtained by conversion into the calcium salt and decomposing this salt with hydrochloric acid (Coppola, G. 13, 522).

***o*-Fluoro-hippuric acid** [121°]. Crystallises in prismatic, iridescent needles, v. sol. ether and alcohol, sl. sol. chloroform, insol. carbon disulphide and benzene. It is decomposed by fuming hydrochloric acid into glycocholic and *o*-fluoro-benzoic acid.

***m*-Fluoro-hippuric acid** [153°]. Prismatic needles, v. sol. hot water, alcohol and ether, insol. carbon disulphide and chloroform.— $\text{CaA'}$ , 2aq: rectangular laminae.— $\text{PbA'}$ , 5aq: small laminae.— $\text{AgA'}$ : flocculent pp.

***p*-Fluoro-hippuric acid** [161°]. Pearly needles (from ether). Insol. benzene,  $\text{CS}_2$ , and chloroform, sol. alcohol, ether, and boiling water.— $\text{CaA'}$ , 2aq: four-sided tables, v. e. sol. water and alcohol.

***p*-FLUORO-iodo-BENZENE**  $\text{C}_6\text{H}_3\text{IF}$  [1.4]. (183°). Formed by decomposing *p*-fluoro-diazobenzene piperidine with conc. hydriodic acid (Wallach a. Heusler, A. 243, 227). Oil, volatile with steam, solidifies at low temperatures. Conc.  $\text{HNO}_3$  liberates iodine with the formation of fluoro-nitro-benzene.

***p*-FLUORO-NITRO-BENZENE**  $\text{C}_6\text{H}_3\text{F(NO}_2\text{)}$ . [24°]. (205°). S.G. 1.326. Formed from  $\text{C}_6\text{H}_3(\text{NO}_2)\text{N}_2\text{NC}_6\text{H}_3$  and conc. HF (Wallach, A. 235, 264). Formed also by nitration of fluorobenzene. Oil, heavier than water; smells like almonds.

**FLUORO-*p*-OXY-BENZOIC ACID.** **Methyl derivative**  $\text{C}_6\text{H}_3\text{F(OMe).CO}_2\text{H}$ . **Fluoro-anisic acid.** [204°]. From amido-anisic acid [181°] by the diazo-reaction (Paternò a. Oliveri, G. 12, 82). Colourless needles, sol. water and alcohol.

***p*-FLUORO-PHENOL**  $\text{C}_6\text{H}_3\text{F.OH}$  [1.4]. (187°). Formed by diazotising *p*-fluoro-aniline and boiling with water (Wallach a. Heusler, A. 243, 228). Solid at ordinary temperatures.

**DI-FLUORO-DIPHENYL**  $C_6H_4F_2$ , i.e.  $F_2C_6H_4C_6H_4F_2$ . [89°]. (255°). Formed by decomposing bi-diazo-diphenyldipiperide with conc.  $HFAq$  (Wallach a. Heussler, A. 243, 234). Crystalline, v. sol. alcohol, ether.

**p-FLUORO-TOLUENE**  $CH_3C_6H_4F$ . (117° i. v.). S.G. 1.992. Prepared by heating its sulphonic acid (obtained from (1, 4, 2) amido-toluene sulphonic acid) with conc.  $HClAq$  in sealed tubes (Paternò a. Oliveri, G. 13, 535). Obtained also from p-diazo-toluene piperide and conc.  $HF$  (Wallach, A. 235, 261). Smells like benzonitrile.  $CrO_3$  and aqueous  $H_2SO_4$  at 160° give p-fluoro-benzoic acid [182°].

**FLUORO-TOLUIC ACID**  $C_6H_4MeF.CO_2H$  [4:3:1]. [161°]. From amido-toluic acid [165°] by the diazo-reaction (Paternò a. Oliveri, G. 12, 88). Needles, sol. water and alcohol.

**FLUORSPAR. Calcium fluoride** (v. vol. I. p. 665).

**FOOT-MUCIN** v. PROTEIDS, Appendix C.

**FORMAMIDINE**  $CH_3N_2$ , i.e.  $NH_2CH:NH$ . *Amido-imido-methane. Formimidamide. Methenylamidine*. Formed from the compound  $(HON)_3HCl$  by decomposing it with alcohol at 100°: the products being formic ether and formamide (Gautier, A. 145, 113; Claisen a. Matthews, C. J. 41, 266). Formed also by the action of alcoholic ammonia on formimido-ether  $NH_2CH:OEt$  (Pinner, B. 16, 357). Hydrochloride  $B'HCl$ . [81°]. Crystallises from alcohol in warty masses or in flat transparent plates. Very hygroscopic. Split up at 100° into  $HCN$  and  $NH_3$ . Potash gives formic acid and  $NH_3$ . Heated with acetic anhydride and sodium acetate it yields di-acetyl-formimidamide and tri-acetyl-formamidil  $C_6H_5Ac_3N_3$  [224°] (Pinner, B. 17, 171).

*Platinochloride*  $B'_2H_2PtCl_4$ : orange octahedra, v. sol. water.

*Di-acetyl-derivative*  $NHAc.CH:NAC$ . Formed as above and together with a dibasic isomeride by heating orthoformic ether with acetamide at 180° (Wichelhaus, B. 3, 2). Short thick prisms, sublimes without melting (Pinner, B. 16, 1660). Sl. sol. cold water, v. al. sol. alcohol.

**FORMAMIDOXIM**  $CH_3N_2O$ , i.e.  $NH_2CH:NOH$ . *Isouretine. Methenyl-amidoxim*. [105°]. Mol. w. 60. Formed by the action of an alcoholic solution of hydroxylamine on a concentrated aqueous solution of  $HCN$  in the cold; the product is evaporated at 40° (Lossen a. Schifferdecker, A. 166, 295). Trimetric prisms (from alcohol). V. sol. water, al. sol. cold alcohol. Its aqueous solution is alkaline in reaction and ppts. salts of Cu, Pb, and Hg. At 140° it splits up into  $CO_2$ ,  $NH_3$ , and ammeline. Boiling water resolves it into formic acid, nitrogen, and  $NH_3$ ; a small quantity (1 pt.) of water when heated with it (1 pt.) gives biuret, urea, guanidine,  $CO_2$ , nitrogen, and  $NH_3$ . Dilute acids split it up into formic acid,  $NH_3$ , and hydroxylamine.

**Salts.**— $B'HCl$ . [60°]. Very deliquescent trimetric tables, al. sol. alcohol.— $B'_2H_2SO_4$ : needles, v. e. sol. water.— $B'_2H_2CO_3$ : flat prisms, m. sol. water.— $B'_2C_2H_5(NO_3)_2OH$ : yellow prisms; m. sol. water and alcohol.— $CH_3N_2OH.HgCl_2$ : yellow flocculent pp. got by adding  $HgCl_2$  to a

solution of formamidoxim. Explodes when heated. V. sol.  $HClAq$ .

**FORM-ANHYDRO. COMPOUNDS** v. METHENYL-COMPOUNDS.

**FORMIC ACID**  $H.COOH$ . *Hydrogen carboxylic acid*. Mol. w. 46. [2°] (Bannoco); [8-6°] (Berthelot, Pettersson, Ekstrand). (100°) (Schiff, Landolt, Person); (100-8°) (Zander); (101°) (Roscoe). S.G.  $\frac{4}{4}$  1.2415;  $\frac{2}{4}$  1.245;  $\frac{11}{4}$  1.231;  $\frac{12}{4}$  1.225;  $\frac{12.5}{4}$  1.22;  $\frac{27}{4}$  1.209;  $\frac{27.5}{4}$  1.2029 (Pettersson, J. pr. [2] 24, 297);  $\frac{28}{4}$  1.219 (Brühl);  $\frac{4}{4}$  1.1829;  $\frac{28}{4}$  1.1649 (Perkin);  $\frac{100.5}{4}$  1.117 (Zander). S.V. 41.08 (Schiff); 41.1 (Zander). V.D. (at 111.5°) 2.88 corresponding to molecular formula  $2H_2CO_3$ ; (at 160°) 1.81; (at 214°) 1.62 (Pettersson and Ekstrand, B. 13, 1194). S.H. (0°-100°) .519 (Pettersson). C.E. (0°-10°) .0697; (0°-20°) .0196; (0°-50°) .0509; (0°-100°) .11 (Zander, A. 224, 56). H.C. (at 100°) 70.750. H.F.p. 95.980. H.F.v. 95.350 (Thomson). M.M. 1.671 (Perkin). R<sub>2</sub> 13.61. A<sup>3</sup> (Constant of capillarity) 5.284 (H. Schiff). Heat of solution in water 2.85 (sol.), .08 (liq.) (Berthelot). Latent heat of fusion 57.88 (Pettersson).

**Occurrence.**—1. In the red ant (*Formica rufa*), from whence the acid derives its name (Marrgat, Diss. Upsala, 1777).—2. In caterpillars, especially *Bombyx processionea* (Will, J. 1847-8, 546), and *Cerura dicranura*, the secretion of which contains 87.5 p.c. of the acid (Poulton, B. A. 1887, 766).—3. In various secretions of the human body, viz. the blood, spleen (Scheerer, A. 69, 199) and sweat (Schottin, J. 1852, 704).—4. In plants, viz. stinging nettles (Gorup Besanetz, A. 72, 267), the fruit of the soap tree, *Sapindus saponaria* (ibid. A. 69, 869), in tamarinds, and in the needles of *Pinus abies* (Redtenbacher, A. 47, 148). It is also found as one of the products of oxidation of crude turpentine oil (Weppen, A. 34, 235; 41, 204; Laurent, J. pr. 27, 316).—5. In the mineral waters of Prins Løten (Pettenkofer, Kastn. Archiv, 7, 104), of Brückenau (Scheerer, A. 99, 257), and in the deposit from the waters of Marienbad.

**Synthesis.**—1. By passing carbonic oxide into damp alkali heated to 100°:  $CO + KHO = KCOOK$  (Berthelot, C. R. 41, 956); the reaction takes place best with soda-lime heated to 190°-200°; above this temperature the formate is decomposed with production of carbonate. If the materials are dry no combination occurs (Merr and Tibirica, B. 13, 23). The addition of alcohol promotes the absorption (Pirritinga, Inaug. Diss., Zurich, 1879).—2. By the action of the silent electric discharge on a mixture of carbonic acid and hydrogen  $CO_2 + H_2 = H_2CO$  (Brodie, Pr. 21, 245).—3. By passing a current of damp carbonic acid over metallic potassium  $2CO_2 + K_2 + OH_2 = HCOOK + KHCO_3$  (Kolbe and Schmitt, A. 119, 251).

**Formation.**—1. By the oxidation of wood spirit (Dumas a. Peligot, A. 15, 7; Dumas a. Stas, ibid. 35, 187).—2. By heating wood spirit with a mixture of lime and potash (Dumas a. Stas).—3. By heating hydrocyanic acid with concentrated alkalis or mineral acids (Pelouze, A. Ch. [2] 43, 395; Geiger, A. 1, 44).—4. By the decomposition of oxalic acid by heat (Gay-Lussac, A. Ch. [2] 46, 218). The yield is much increased by addition of glycerin or mannite

(Berthelot, *v. infra*). An aqueous solution of oxalic acid in presence of uranic oxide is decomposed by sunlight into  $\text{CO}_2$  and formic acid (Seekamp, *A.* 123, 113).—6. By decomposition of chloral and trihalogen derivatives of methane (Liebig, *A.* 1, 198; Dumas, *B.* 7, 15, 371), or, by heating chloroform with aqueous  $\text{NH}_3$  in sealed tubes at  $200^\circ\text{--}225^\circ$ ,  $2\text{CHCl}_3 + 7\text{NH}_3 + 8\text{H}_2\text{O} = \text{CO} + 6\text{NH}_4\text{Cl} + \text{HCOONH}_4$  (André, *C. R.* 102, 558).—6. By adding sodium amalgam to a strong aqueous solution of ammonium carbonate ( $\text{NH}_4)_2\text{CO}_3 + \text{Na}_2 = \text{HCO}_2\text{Na} + 2\text{NH}_3 + \text{NaOH}$  (Maly, *A.* 135, 119).—7. By distilling starch, sugar, and various albuminous substances with manganese peroxide and sulphuric acid (Döbereiner, *A.* 3, 144; Gmelin, *P.* 16, 55). Other organic substances, such as tartaric acid, gum, linsed oil, woody fibre, and cereal grains, yield formic acid when distilled with concentrated sulphuric acid with or without manganese peroxide. 8. By the electrolysis of water through which a current of  $\text{CO}_2$  is passed (Royer, *Z.* 1870, 318). 9. By the oxidation of coal-gas by ozone (Maquenne, *Bl.* [2] 87, 298).—10. By heating alcohol with nitric acid (Gaultier de Claubry, *J. Ph.* 25, 764).—11. By oxidation of tri-methylamine with alkaline permanganate (Wallach a. Claisen, *B.* 8, 1288).—12. By the oxidation of carbon (from carbon disulphide) with potassium permanganate (Chapman, *C. J.* 5, 183).—13. As an iron-salt by heating carbon disulphide with water and iron filings (Loew, *B.* 13, 324).—14. By heating lactic acid with sulphuric acid (Erlenmeyer).

**Additional references.**—Hulse and Fisher, *T.* 1670, vol. v. 2063; Wöhler, *P.* 15, 307; Hünefeld, *J. pr.* 7, 44; Guckelberger, *A.* 64, 39; Stenhouse, *P. M.* [3] 18, 122; Sacc, *A.* 51, 214; Hlasiwetz, *J. pr.* 51, 355; Liebig, *A.* 17, 69; Gehlen, *A. Ch.* [1] 83, 208; Limpricht, *A.* 97, 361; Hurst, *C. J.* 15, 278.

**Preparation.**—1. By heating to  $60^\circ$  in a capacious retort a solution of sugar (1 pt.) in water (2 pts.) with manganese peroxide (2.5–3 pts.) and 1:1 sulphuric acid (3 pts.). One-third of the acid is added at first; when the violence of the reaction has abated the remainder of the acid is added. The acid formed is condensed in a receiver, and at the end of the action the distillate is neutralised with chalk, and the filtrate evaporated to the point of crystallisation. The calcium salt is converted into the lead salt by addition of lead carbonate, and the lead salt decomposed by the requisite quantity of sulphuric acid.—2. By heating equal parts of anhydrous glycerin (or mannite) and crystallised oxalic acid in a retort to  $75^\circ\text{--}90^\circ$ , until carbonic acid is no longer evolved. A fresh portion of oxalic acid is then added, and the distillation continued. This process may be repeated several times. The distillate finally contains 55 p.c. of the acid, and is redistilled over anhydrous oxalic acid when a 75 p.c. acid is obtained. This is neutralised with sodium carbonate, the dry sodium salt distilled with anhydrous oxalic acid, when a 99 p.c. acid is obtained (Lorin). The last trace of water is removed by distillation over boric anhydride, or the acid is subjected several times to a freezing mixture, the crystals separated from the liquor, and then allowed to melt, or the dry lead (or copper) salt is heated at  $180^\circ$  in a current of dry hydrogen sulphide; in the latter

case the product is apt to be contaminated with sulphur products (Liebig; Wöhler).

In the above process the crystallised oxalic acid decomposes into water, carbonic acid and formic acid, the last of which combines with the glycerin to produce monoformin, which is subsequently decomposed by water into glycerin and formic acid, the equation being  $\text{C}_3\text{H}_7(\text{OH})_2 + \text{H}_2\text{C}_2\text{O}_4 = \text{C}_3\text{H}_7(\text{OH})(\text{OCHO}) + \text{H}_2\text{O} + \text{CO}_2 = \text{C}_3\text{H}_7(\text{OH})_2 + \text{H}_2\text{CO}_3 + \text{CO}_2$ . The details of the process have been worked out by Lorin, *Bl.* [2] 5, 7, 12; 20, 241; 24, 22, 436; 25, 517; 87, 104.

**Properties.**—The acid solidifies below  $0^\circ$  and exhibits the phenomenon of superfusion. The liquid acid is colourless, transparent, and mobile. It has a pungent sour taste and odour, and when concentrated blisters the skin (Liebig).

The vapour pressure of the acid at various temperatures has been determined by Landolt (*A. Suppl.* 6, 164) and Richardson (*C. J.* 49, 765), some of whose results are given below:—

Temperature.	Pressure in mm.	Temperature.	Pressure in mm.
5.7	13.46 R.	45	102.7 L.
10	18.4 L.	60	191.2 L.
10.2	17.44 R.	70	280 L.
20	31.4 L.	80	399.8 L.
29.7	48.33 R.	82.7	391.2 R.
30	51.6 L.	90	558 L.
40	82.3 L.	91.2	529.3 R.
44.5	82.97 R.		

**Aqueous acid.**—Formic acid mixes in all proportions with water. By distillation of aqueous formic acid at standard pressure a 77 p.c. acid ( $107^\circ$ ) is finally obtained, whatever the original strength: this corresponds to an acid of molecular composition  $\text{HCOOH} + \text{H}_2\text{O}$ , and has been termed orthoformic acid  $\text{CH}(\text{OH})_2$ , the ethereal salts of which are described below. But on alteration of pressure the composition as well as the boiling-point alter; thus at 1350 mm. an 80 p.c. acid ( $124.1^\circ$ ), and at 1830 mm. an 83 p.c. acid ( $134.6^\circ$ ) finally distil (Roscoe, *C. J.* 15, 270). Perkin (*C. J.* 49, 778) also concludes that the so-called hydrate S.G.  $\frac{1}{4}$  1.1829 is only a mixture of the acid and water.

A 30 p.c. aqueous acid has the maximum electric conductivity (Hartwig, *W.* 35, 58).

**Reactions.**—1. The acid is completely resolved by strong sulphuric acid into carbonic oxide and water (Döbereiner); this reaction at a temperature of  $60^\circ\text{--}80^\circ$  starts at first slowly, reaches a maximum and then decreases at a rate proportional to the mass of acid undergoing decomposition (Veley, *T.* 1888, 274, 286–297).—2. The vapour of the concentrated acid burns with a dull blue flame (Liebig).—3. It is slowly burnt when dropped on platinum black (Döbereiner).—4. Gradually oxidised by chlorine (Clow), more rapidly by aqueous iodic or periodic acid (Benckieser, *A.* 17, 258; Millon, *C. R.* 19, 271).—5. Decomposed by nitric acid (Arvidson).—6. Heated with zinc dust it is decomposed into carbonic oxide and hydrogen (Jahn, *M.* 1, 679).—7. Forms with bromine in presence of carbon disulphide an unstable addition product, which decomposes into  $\text{HBr}$  and  $\text{CO}_2$  (Hell a. Mühlhauser *B.* 11, 245).—8. On electrolysis it yields  $\text{O}_2$ ,  $\text{H}_2$  and as a secondary product acetic acid (Boussin

**A. Ch.** [4] 14, 185).—9. Decomposed by silent electric discharge into  $\text{CO}$ ,  $\text{CO}_2$ , and  $\text{H}_2$ , the proportion of the two former depending on the pressure (Maquenne, *C. R.* 98, 68).—10. The acid acts as a strong reducing agent, precipitating in alkaline solution the heavy metals, gold, platinum, and palladium from their solutions. With silver nitrate it precipitates silver formate, which is subsequently reduced to the metal; it converts mercuric into mercurous chloride, and only on protracted heating to metallic mercury. In acid solution it reduces potassium permanganate in the cold, and chromic acid when heated, and is thus distinguished and separated from acetic acid. It also reduces Fehling's solution. These reducing properties are attributed to the presence of the aldehydic group  $\text{CHO}$  in the acid.—11. The acid and its salts act as powerful antiseptics and anti-fermentatives (Jodin, *C. R.* 61, 1179; Hoffmann, *Inaug. Diss.*, Greisswald, 1884). Injected into the system they lower the temperature and blood pressure, and retard the heart's action (*Jahresber. Fort. Pharm.* 1879, 127).

**Detection.**—1. The solution supposed to contain the acid or its salts is heated with concentrated sulphuric acid, when carbonic oxide only is evolved.—2. With silver nitrate they give a white pp. turning brownish-black on boiling (*v. supra*).—3. With mercurous nitrate they give a white pp. turning grey from separation of the metal.

**Estimation.**—1. The acid or salt is heated for 1½ hours with sodium acetate and a normal solution of mercuric chloride, the excess of which is titrated with potassium iodide. Results 5 p.c. too low (Portes a. Ruysen, *C. R.* 82, 1504).—2. By a standard solution of potassium permanganate acidified with dilute sulphuric acid.—3. By measurement of the volume of carbonic oxide given off by concentrated sulphuric acid.

**Formates.**—Formic acid is monobasic, the general formula of its normal salts being  $\text{R}(\text{HCOO}) = \text{R}_2\text{A}$ ; double salts are also known of formula  $\text{R}_2\text{A} \cdot \text{R}'_2\text{A}$ .

**METALLIC FORMATES.**—The salts are all soluble in water. Those of the fixed alkalis when heated are converted into the oxalates with evolution of hydrogen; those of the heavy metals yield the metal. The barium and calcium salts heated with the barium or calcium salts of the carboxylic acids yield the aldehydes, vol. i. p. 107. The salts when heated with water in sealed tubes at  $175^\circ$  are more or less completely decomposed, those of  $\text{Ca}$ ,  $\text{Mg}$ ,  $\text{Mn}$ ,  $\text{Fe}$ ,  $\text{Co}$ ,  $\text{Ni}$ ,  $\text{Zn}$ ,  $\text{Sn}$ ,  $\text{Pb}$ ,  $\text{Cu}$ ,  $\text{Hg}$ ,  $\text{Ag}$ , yielding an oxide or carbonate with evolution of  $\text{H}_2$ ,  $\text{CO}_2$ , and  $\text{CO}$ . In the case of the  $\text{Co}$  and  $\text{Ni}$  salts some of the metal separates, possessing highly magnetic properties; from the  $\text{Cu}$  salt  $\text{Cu}_2\text{O}$  separates in violet crystals mixed with the metal also in crystals (Riban, *C. R.* 93, 1023, 1032; cf. Berthelot, *ibid.* 1051).

The formates have been examined by Göbel, Schweig, Döbereiner and Liebig; Crystallographic measurements by Heusser (*P.* 83, 87); Handl, *Sitzb. W.* 42, 747; Zepharovich, *ibid.* 43, ii. 545; v. Hauer, *ibid.* 548; cf. *J.* 1861, 430; Rammelsberg, *Hand. Krypt. Chem.* 274; Voss, *Inaug. Diss.*, Königsberg, 1887; Specific Gravities, by Clarke, *B.* 12, 1399; Schröder, *B.* 14, 31; Heats of Solution and Formation, Berthelot,

*C. R.* 77, 24; Refraction Equivalent, Gladstone, *Pr.* 16, 441; Kanonnikow, *J. R.* 16, 124; Dispersion (crystals), v. Lang, *Sitzb. W.* 31, 105; Descloizeaux, *Ann. M.* 11, 261.

Aluminium formate, obtained by ppg. barium formate with equivalent proportion of aluminium sulphate; crystallises with difficulty, decomposed by hot water with ppn. of aluminium hydrate (Liebig).

Ammonium formate  $\text{NH}_4\text{A}$ : monoclinic crystals,  $a:b:c = 884:1:1269$ ;  $\beta = 1269$ , S.G. 1.266 (Schröder). Heat of solution  $-2.94$ . Decomposes when quickly heated to  $180^\circ$  into formamide and water but no hydrocyanic acid (Andreasch), while at a higher temperature hydrocyanic acid only is produced (Döbereiner).

Barium formate  $\text{BaA}$ : monoclinic crystals,  $a:b:c = 765:1:864$  (Heusser). S.G. 3.212 (Schröder), 3.471 (Clarke). Heat of solution  $-2.44$ . S. 20 to 25 in the cold; insol. alcohol and ether.— $\text{BaA}$ , 2aq (Krasnicki, *M.* 8, 599).

Formonitrate  $\text{BaNO}_3\text{A}$ , 2aq (Ingenhous, *B.* 12, 1680).

Double salts. Barium-zinc  $\text{BaA} \cdot \text{ZnA}$ , 2aq: triclinic crystals,  $a:b:c = 579:1:452$ ;  $\beta = 108^\circ 49'$  (Heusser; Voss).—Barium-manganese salt  $\text{BaA} \cdot \text{MnA}$ , 2aq: monoclinic crystals,  $a:b:c = 1:759:917$  (Heusser).—Barium-cobalt salt  $\text{BaA} \cdot \text{CoA}$ , 2aq: triclinic, isomorphous with the barium-zinc salt, as also Barium-nickel salt  $\text{BaA} \cdot \text{NiA}$ , 2aq, and Barium-copper salt  $\text{BaA} \cdot \text{CuA}$ , 2aq (Heusser; Voss).—Barium-copper 2BaA, CuA, 2aq: triclinic crystals, S.G. 3.2747. Barium-cadmium  $\text{BaA} \cdot \text{CdA}$ , 2aq: monoclinic crystals,  $a:b:c = 898:1:54$ . S.G. 3.2724.

Bismuth formate. White crystals, readily sol. water.

Cadmium formate  $\text{CdA}$ , aq: monoclinic prisms,  $a:b:c = 1325:1:1224$ ;  $\beta = 97^\circ 5'$  (Kopp). S.G. 2.429 (Clarke), 2.477 (Schröder), readily sol. water, dehydrated with difficulty.

Calcium formate  $\text{CaA}$ : rhombic crystals,  $a:b:c = 759:1:467$ . S.G. 2.021 (Schröder). Heat of solution  $-66$ . S. 10 to 12.5 in the cold, insol. alcohol. Forms methyl alcohol on dry distillation.

Cerium formate  $\text{CeA}$ , aq, prepared by ppg. a solution of cerous chloride with sodium formate, rose-coloured, crystalline powder, converted into ceroso-ceric oxide, when heated.

Cobalt formate  $\text{CoA}$ , 2aq: rose-red crystals. S.G. 2.2866. S. 20 at  $20^\circ$  Voss.

Copper formate  $\text{CuA}$ : blue transparent monoclinic crystals,  $a:b:c = 1:996:771$ . S.G. 1.831 (Schröder). Heat of solution  $-7.84$  (hydrated),  $.52$  (anhydrous). Prepared by neutralising formic acid with copper carbonate or freshly ppd. oxide, and spontaneously evaporating. If the solution is heated the basic salt separates out. S. 12.5 to 25 in the cold. S. (80 p.c. alcohol)  $-25$ .

Basic salt  $\text{CuA} \cdot 2\text{Cu}(\text{OH})_2$ : pale-green powder, insoluble; prepared by boiling an aqueous solution of the normal salt.

Double salts. Copper hydrogen

$\text{CuA} \cdot \text{HA}$ , 1½aq: blue, rhombic, six-sided tables,  $a:b:c = 1324:1:1765$ , separated, together with the  $\text{CuSr}$  salt, from a strongly acid solution of 2 mols.  $\text{SrA}$ , and 1 mol.  $\text{CuA}$ , (Zepharovich). Copper strontium  $2\text{SrA} \cdot \text{CuA}$ , 3aq: triclinic crystals,  $a:b:c = 744:1:10103$  (Zepharovich), and

# FORMIO ACID.

**ErA',Ond',4aq.** S.G. 2 138 (hydr.), 2-612 (anhyd.), Schröder.

**Didymium formate DiA',** S.G. 3-43. S.V.S. 80-8. Violet powder, v. al. sol. water (Clève, Bl. [9] 43, 865).

**Erbium formate ErA',4aq:** red crystals (Clève, C. R. 91, 882).

**Iron formates. Ferrous formate** FeA',2aq, v. al. sol. water (Scheurer-Kestner, A. Ch. [3] 68, 480).

**Ferric formate** FeA',aq: yellow glistening crystals, obtained by dissolving recently precipitated ferric hydrate in formic acid; from its solution ferric hydrate gradually separates, while a basic salt remains in solution (Scheurer-Kestner; cf. Ludwig, J. 1861, 438). **Formo-nitrate** FeA',(NO<sub>3</sub>)(OH),8aq: yellow crystals, readily decomposed. **Formo-chloride** FeA',Cl,3aq: reddish-yellow salt, v. al. sol. water (Scheurer-Kestner).

**Lead formate** PbA': rhombic prisms or needles, isomorphous with barium salt (Heusser). S.G. 4-571 (Bödeker, J. 1860, 17; Schröder). Heat of solution -3-45. S. 1-6 at 16°, 18 at 100° (Barfoed, Z. 1870, 272). Insol. alcohol, thus differing from lead acetate. The dry salt decomposes at 190°, thus Pb(OHO)<sub>2</sub> -2CO<sub>2</sub>+H<sub>2</sub>+Pb. **Basic salts.** By boiling aqueous solution with lead oxide the following basic salts separate out. PbA<sub>2</sub>PbO, prisms, sol. 58-5 pts. cold water, PbA<sub>2</sub>PbO. Sol. 25-5 pts. cold, 7-5 pts. water (100°), of strong alkaline reaction, PbA<sub>2</sub>3PbO crystalline pp. sol. 90 pts. cold water (Barfoed).

**Formonitrate** 8PbA'.Pb(NO<sub>3</sub>),2aq: rhombic tables, v. al. sol. (Lucius, A. 103, 115).

**Lithium formate** LiA',aq: rhombic crystals, a:b:c=1:651:484 (Handl). S.G. 1-435-1-479 (Schröder).

**Magnesium formate** MgA',2aq: rhombic prisms and octahedra. S. 7-7, insol. alcohol and ether (Souchay a. Groll, J. pr. 76, 470).

**Manganese formate** MnA',2aq: monoclinic crystals, a:b:c=1-317:1:1-213; β=97° 38' (Heusser; Voss). S.G. 1-953 (hydr.), 2-205 (anhyd.) (Schröder).

**Mercurous formate** Hg<sub>2</sub>A': glistening scales. S. 4 at 17°, decomposed when boiled with water, Hg<sub>2</sub>(OHO)<sub>2</sub>=Hg<sub>2</sub>+H<sub>2</sub>CO<sub>3</sub>+CO<sub>2</sub> (Göbel).

**Nickel formate** NiA',2aq: green crystals. S.G. 2-1547 (Clarke).

**Potassium formate** KA'. Deliquescent, rhombic cubes. S.G. 1-908. [150°]. Heat of solution -98.

**Samarium formate** SmA': white powder, v. al. sol.

**Silver formate** AgA': crystalline pp. formed by adding silver nitrate to an alkaline formate, completely decomposed on boiling with water, 2AgCHO=Ag<sub>2</sub>+CO<sub>2</sub>+H<sub>2</sub>CO<sub>3</sub>, thus differing from the acetate. e

**Sodium formate** NaA': rhombic prisms, a:b:c=919:1:97; β=58° 9' (Fock, Z. K. 7, 61). M.P. 200°. M. sol. (water), al. sol. (alcohol), insol. (ether). S.G. 1-919 (Schröder). Heat of solution -52. Decomposed when heated into hydrogen and the oxalate: 2NaCHO=H<sub>2</sub>+Na<sub>2</sub>C<sub>2</sub>O<sub>4</sub>. -NaA<sub>2</sub>aq, rhombic tables, sol. 2 pts. (water). The acid salts of sodium and potassium described by Bineau do not exist.

**Strontium formate** SrA',2aq: rhom-

bic crystals, a:b:c=608:1:595 (Heusser), exhibiting hemihedral forms (Pasteur, A. Ch. [7] 51, 98; Jacobsen, P. 118, 496). S.G. 2-25 (hydr.), 2-667 (anhyd.) (Schröder). Heat of solution 2-78 (hydr.), 81 (anhyd.), m. sol. (water).

**Terbium formate**, white powder. M. sol. water.

**Thallium formate** TlA': v. sol. water; melts below 100° without decomposition (Kuhlmann, C. R. 55, 607).

**Thorium formate** ThA',4aq: tables, deliquescent (Chydenius, P. 119, 54).

**Ytterbium formate** YbA',4aq: crystalline aggregates (Marignac, A. Ch. [5] 14, 247).

**Yttrium formate**, very soluble, deliquescent. The philippium formate described by De lafontaine, A. Ch. [5] 14, 238 is probably a mixture of terbium and yttrium formates, which separates in rhombic prisms, a:b:c=89:1:1-484 (Roscoe, C. J. 41, 281).

**Zinc formate** ZnA',2aq: monoclinic crystals, isomorphous with Mn salt. S.G. 2-151 (hydr.) (Schröder); 2-157 (Clarke), 2-306 (anhyd.). Heat of solution -1-2 (hydr.), 1-97 (anhyd.).

## ALKYL FORMATES. Formic ethers.

**Methyl ether** C<sub>2</sub>H<sub>5</sub>O<sub>2</sub> or MeA'. Mol. w. 60. S.G. 3-93-957 (S.); 2-978 (E.); 1-982, 2-969 (Perkin); 1-979 (Grodzki a. Krämer). V.D. 2-084 (for 2-08) (Dumas a. Peligot). C.E. (0°-10°) 0-0144 (E.). S.V. 62-57 (S.), 62-84 (E.), 63-2 (Ramsay). H.C.v. 241,620 (Thomson), 238,700 (Berthelot). H.F.p. 89,430. H.F.v. 88,270. M.M. 2-495 at 16° (P.). A<sup>2</sup> 4-944 (S.).

**Occurrence.**—In crude wood spirit (Mabery, A. C. J. 5, 259).

**Preparation.**—1. By adding calcium formate (100 pts.) gradually to wood spirit (180 pts.), saturated with hydrochloric acid. The distillate is poured back, redistilled, and finally rectified over sodium carbonate and calcium chloride (Volhard, A. 176, 133).—2. By distilling a mixture in equivalent proportions of sodium formate, hydrochloric acid, and wood spirit (Bardy a. Bordet, A. Ch. [5] 18, 561; cf. Dumas a. Peligot, A. Ch. [2] 58, 48).

**Properties.**—Colourless liquid of ethereal odour.

**Mono-chloro-methyl formate** C<sub>2</sub>H<sub>5</sub>CO<sub>2</sub>Cl. Prepared by passing chlorine in the dark at 100° into methyl formate.

**Perchloromethyl formate** CCl<sub>3</sub>CO<sub>2</sub>Cl (180°-185°). S.G. 1-724 (Oahours, A. 64, 815). When passed through a strongly heated tube it is converted into carbon oxy-chloride. With alcohol it forms ethyl chloro-formate, the equation being C<sub>2</sub>Cl<sub>3</sub>O<sub>2</sub>+2EtOH=2C<sub>2</sub>ClCO<sub>2</sub>Et+2HCl.

**Ethyl ether** C<sub>2</sub>H<sub>5</sub>O<sub>2</sub> or EtA'. Mol. w. 74. (53-5°) at 754-5 mm. (R. Schiff); (55°) (Gartenmeister); (54-4°) (Elsässer). S.G. 2-945 (G.); 2-937 (Elsässer); 2-9084 (Brühl); 1-9298, 2-9188 (Perkin); 2-978 (S.) (cf. Naccari a. Pagliani, W. Beibl. 687). V.D. 2-598 (for 2-565) (Liebig). C.E. (0°-10°) 0-01381 (E.). S.V. 84-57 (S.); 84-6 (G.); 85-14 (E.). H.F. 1-8642. R<sub>100</sub> 28-61 (B.). M.M. 8-664 at 18-8. H.F.p. 95,900. H.F.v. 94,160. A<sup>2</sup> 4-528. **Critical Temperature** 288-6° (Fawlewski).

**Preparation.**—1. By distilling a mixture of

# FORMIC ACID.

367

95 p.c. alcohol (6 pts.), sodium formate (7 pts.), and concentrated sulphuric acid (10 pts.) (Ldebig, A. 17, 72).—2. By heating a mixture of glycerin, oxalic acid, and alcohol in a reflux apparatus, and then distilling (Lorin, Bl. [2] 5, 12).—3. Staroh (9 pts.) mixed with manganese peroxide (29 pts.), is added to a mixture of sulphuric acid (20 pts.), water (5 pts.), and 85 p.c. alcohol (15 pts.), and the whole distilled (Stinde, D. P. J. 181, 402).—4. As a secondary product in the preparation of ethyl oxalate (*J. pr.* 83, 1), its formation being due to the decomposition of mono-ethyl oxalate (Anschütz, B. 16, 2412).

**Properties.**—Liquid, of odour resembling peach-kernels. S. 11 at 18°, sol. alcohol and ether. Vapour-tension at various temperatures (Nacolari a. Pagliani):—

Temp.	Pres.	Temp.	Pres.
20.2	193.7	50.3	656.9
31.2	311.2	55.1	782.2
40.87	459.9	60.5	941.9

**Reactions.**—Decomposed by sodium or sodium-ethylate into carbonic oxide and alcohol  $\text{HCO}_2\text{Et} = \text{CO} + \text{EtOH}$  (Gauthier, Z. 1868, 666). With chlorine it yields *di-chloro-ethyl formate*  $\text{HCO}_2\text{C}_2\text{H}_4\text{Cl}_2$ , S.G. 1.261, which is decomposed when boiled, and by alkalis into KCl, potassium formate, and acetate (Malaguti, A. 32, 89); and *per-chloro ethyl formate*  $\text{ClCO}_2\text{C}_2\text{H}_4\text{Cl}$  (*cf.* trichloroacetic acid) (Buchholz, *Crell. N. Entdeck.* 6, 55; Gehlen, S. 4, 18; Döbereiner, A. 3, 145; Kopp, A. 55, 180).

**Propyl ether** *Pr. A.* Mol. w. 88. (81°) at 760 mm. (Gartenmeister, Elsässer, Schumann); (82.5°–83°) at 769.4 mm. (Schiff). S.G. 0.925 (G.);  $\rho$  0.184 (E.);  $\rho$  0.188 (Pierre a. Puchot);  $\rho$  0.909,  $\rho$  0.902 (Perkin);  $\rho$  0.875 (S.). C.E. (0°–10°) 0.01212 (E.); (0°–20°) 0.0246 (Pierre a. Puchot). S.V. 108.7 (S.); 106.2 (G.); 106.8 (E.). H.F.p. 102.480. H.F.v. 100.160. M.M. 4.534.  $\Delta$  4.486. S. 2.2 at 22° (Traube, B. 17, 2304). **Critical temperature**, 267.4 (Pawlewski; Pierre a. Puchot, A. 153, 262; 163, 271).

**Isopropyl ether** *Pr. A.* (68°–71°). S.G. 0.8826 (Pribram a. Handl, M. 2, 686). Specific viscosity 31.5 at 10.4°.

**n-Butyl ether**  $\text{HCO}_2\text{C}_4\text{H}_9$ . (104°–105°) at 789.4 mm. S.G. 0.9058. Specific viscosity 52 at 19° (Pribram a. Handl, *ibid.* 692).

**Isobutyl ether**. (97.9°) at 760 mm. (Schumann, Elsässer); (98.5°) at 759.3 mm. (Schiff). S.G. 0.8854 (E.); 0.8845 (Pierre a. Puchot);  $\rho$  0.7784 (S.). S.V. 127.6 (G.); 130.7 (S.); 129.9 (E.). S. 1 at 22° (Traube, B. 17, 2304). C.E. (0°–10°) 0.0112 (E.; *cf.* Pierre a. Puchot, A. 163, 281). H.F.p. 106.700. H.F.v. 103.800.  $\Delta$  4.064 (S.) (Wurtz, A. 93, 121).

**iso-amyl ether**  $\text{HCO}_2\text{C}_5\text{H}_{11}$ . Mol. w. 116. (128.9°) at 760 mm. (Schumann, Schiff, Elsässer); (130.4°) (Gartenmeister). S.G. 0.9018 (G.); 0.8944 (E.); 0.8803 (Brühl);  $\rho$  0.7564 (S.). S.V. 158.2 (S.); 150.21 (E.); 150.5 (G.). C.E. (0°–10°) 0.0107 (G.).  $\mu$  1.4027.  $R_\infty$  51.06 (B.). **Critical temperature** 304.6.  $\Delta$  4.149 (S.). Prepared by distillation of glycerin, oxalic acid, and fusel oil.

**Hexyl ether**  $\text{HCO}_2\text{C}_6\text{H}_{13}$ . (153.6°) (Gartenmeister); (146°) (Frentzel). S.G. 0.8977 (G.); 0.8495 (E.). S.V. 173.3 (G.). C.E. (0°–10°) 0.0108 (G.).

**Heptyl ether**  $\text{HCO}_2\text{C}_7\text{H}_{15}$ . (176.7°) (Gartenmeister). S.G. 0.8937 (G.). S.V. 198.7 (G.). C.E. (0°–10°) 0.0097.

**Octyl ether**  $\text{HCO}_2\text{C}_8\text{H}_{17}$ . (198.1°) (G.). S.G. 0.8929 (G.). S.V. 220.3 (G.). C.E. (0°–10°) 0.0096.

**Allyl ether**  $\text{HCO}_2\text{C}_3\text{H}_5$ . Mol. w. 86. (82.83°). S.G. 0.8322 (Tollens, Z. 1866, 518; 1868, 441). H.F.p. 65.020. H.F.v. 63.280. Formed as a subsidiary product in the preparation of formic acid from glycerin and oxalic acid when the mixture is not too strongly heated.

**Phenyl ether**  $\text{HCO}_2\text{C}_6\text{H}_5$ . (180° with decomposition). Phenol and formic acid (equiv. pts.) are heated at 80° and  $\text{POCl}_3$  ( $\frac{1}{4}$  equiv.) slowly added (Seifert, *J. pr.* [2] 31, 467).

**Orthoformic acid**. As stated above, though orthoformic acid  $\text{HC(OH)}_3$ , has not been isolated as such, its ethereal salts are stable compounds, prepared by heating chloroform with the alcohol in presence of an alkali metal or hydrate  $\text{CHCl}_3 + 3\text{RONa} = 3\text{NaCl} + \text{CH(OR)}_3$  (Williamson a. Kay, *Pr.* 7, 135).

**Methyl ether**  $\text{HC(OMe)}_2$ . (101°–102°) (Deutsch, B. 12, 117); (102°) (Pinner, B. 16, 1644). S.G. 0.974 (D.). V.D. 52.59 (obs.). H.F.p. 130.460. H.F.v. 127.270. Prepared from methyl alcohol, chloroform, and sodium.

**Ethyl ether**  $\text{HC(OEt)}_2$ . (145°–146°) (Kay); (146°–148°) (Ladenburg a. Wichelhaus, A. 152, 164); (147°–149°) (Deutsch); (145°) (Pinner). S.G. 0.894.

**Formation**.—1. From chloroform and sodium ethylate (Williamson a. Kay).—2. By decomposing the hydrochloride of formimido-ether with alcohol (Pinner).

**Preparation**.—1. Sodium ethylate free from alcohol is mixed with a little ether and chloroform added slowly. The mixture is warmed on a water-bath, then distilled and rectified over  $\text{CaCl}_2$  (Stapff, Z. 1871, 186).—2. Sodium (7 pts.) is added gradually to a mixture of  $\text{CHCl}_3$  (12 pts.), absolute alcohol (14 pts.), and a little ether (Wichelhaus a. Ladenburg, A. 152, 164; Deutsch, B. 12, 116; *cf.* Bassett, C. J. 2, 198).

**Properties**.—Liquid of aromatic odour; liquid at  $-18^\circ$ ; v. sol. water.

**Reactions**.—1. Heated with acetic acid it is decomposed into formic acid and ethyl acetate (Sawitsch, J. 1860, 391).—2. By sodium ethylate it is converted into CO, alcohol, ether, and formic acid (Bassett).—3. With bromine it gives  $\text{EtBr}$ , alcohol, ethyl formate, and ethyl carbonate, according to the equation:  $2\text{HC(OEt)}_2 + \text{Br}_2 = 2\text{EtBr} + \text{HCO}_2\text{Et} + \text{CO(OEt)}_2 + \text{EtOH}$ .

**Dimethyl ethyl ether**  $\text{CH(OMe)}_2\text{OEt}$ . (115°–120°). Prepared by mixing the hydrochloride of formimido-ether with methyl alcohol (Pinner, B. 16, 356).

**Tripropyl ether**  $\text{CH(OPr)}_3$ . (196°–198°) (Deutsch); (194°) (Pinner). S.G. 0.879. V.D. 95.64 (D.).

**Dipropyl methyl ether**  $\text{HC(OPr)}_2\text{OMe}$ . (181°) (P.).

**Dipropyl ethyl ether**  $\text{HC(OPr)}_2\text{OEt}$ . (186°) (P.).

**Dimethyl propyl ether**  $\text{HC(OMe)}_2\text{OPr}$ . (152°) (P.).

**Diethyl propyl ether**  $\text{HC(OEt)}_2\text{OPr}$ . (167°) (P.).

**Dipropyl isoamyl ether**  $\text{HC}(\text{OPr})_2\text{OC}_4\text{H}_9$ . (226°) (P.).

**Propyl di-isobutyl ether**  $\text{HC}(\text{OPr})(\text{OC}_4\text{H}_9)_2$ . (208°) (P.).

**Tri-isobutyl ether**  $\text{HC}(\text{OC}_4\text{H}_9)_3$ . (220°-222°). S.G. 0.861. V.D. 114-86 (Deutsch).

**Diisobutyl isoamyl ether**  $\text{HC}(\text{OC}_4\text{H}_9)_2(\text{OC}_5\text{H}_{11})$ . (232°) (P.).

**Di-isoamyl ethyl ether**  $\text{HC}(\text{OC}_5\text{H}_{11})_2\text{OC}_2\text{H}_5$ . (254°) (P.).

**Triallyl ether**  $\text{CH}(\text{OC}_3\text{H}_5)_3$ . (196°-205°). Prepared from sodium (16 g.), allyl alcohol (85 g.), and chloroform (24 g.), diluted with double its volume of petroleum (Beilstein a. Wiegand).

**Phenyl ether**  $\text{CH}(\text{OPh})_2$ . (72°) (Tiemann, B. 15, 2686); (76°-77°) (Auwers, B. 18, 2657). (270° at 55 mm.) (T.). Long needles; insol. water, sol. ether, chloroform, and benzene. Formed by the action of chloroform on alkaline phenol solution. Readily decomposed by acids, not by alkalis.

**o-Nitro phenyl ether**  $\text{CH}(\text{OC}_6\text{H}_4\text{NO})_2$ . (182°). From chloroform (2 mols.) and potassium o-nitro phenol (3 mols.), heated to 150°. Yield small. Needles (Weddige, J. pr. [2] 26, 445).

**p-Nitro phenyl ether**. (232°). Needles. Prepared as above (Weddige).

**Formamide**  $\text{CH}_3\text{NO}$  i.e.  $\text{HCONH}_2$ . *Amide of formic acid*. Mol. w. 45. (192°-195°) with decomposition into carbonic oxide and ammonia; (140° in vacuo) (Hofmann, C. J. 16, 72); (208°) (Claisen a. Matthews, C. J. 41, 264); (150° in vacuo) (Schulze, J. pr. [2] 27, 516).

**Formation**.—1. By heating ethyl formate with ammonia (Hofmann).—2. By heating ammonium formate together with urea at 140° (Berend, A. 128, 335):  $2\text{HCO}_2\text{NH}_4 + \text{CO}(\text{NH}_2)_2 = 2\text{HCO}_2\text{NH}_2 + (\text{NH}_4)_2\text{CO}_3$ .—3. By the action of sodium-amalgam on a solution of potassium cyanate (Basarow, B. 4, 409).—4. By the action of strong fuming  $\text{HCl}$  on  $\text{HCN}$  (Claisen a. Matthews).

**Preparation**.—1. Ammonium formate is heated at 230° for five hours under pressure, yield 71 p.c. of theoretical (Hofmann, B. 15, 980).—2. By heating dry formic acid (55 g.) with ammonium sulphocyanide (31 g.) for two days, and then distilling in vacuo. Yield 74 p.c.

**Properties**.—Liquid, sol. water, alcohol and ether.

**Reactions**.—1. Decomposed by alkalis in the cold with evolution of  $\text{NH}_3$ .—2. Split up by  $\text{PCl}_5$  into  $\text{CO}$  and a little  $\text{HCN}$  (Wallach, B. 15, 210).—3. With  $\text{P}_2\text{O}_5$  it yields  $\text{HCON}$  (Hofmann).—4. It absorbs dry  $\text{HCl}$  in the cold with formation of a crystalline addition product, which at a higher temperature is completely resolved into  $\text{NH}_4\text{Cl}$  and  $\text{CO}$ .—5. With bromine in equimolecular proportions in presence of soda it forms a crystalline bromo-derivative  $\text{HCONHBr}$ , decomposed into  $\text{HBr}$  and  $\text{H}_2\text{C}_2\text{N}_2\text{O}_2$  (Hofmann, B. 15, 753).—6. With ethyl aceto-acetate in presence of zinc chloride it yields di-methyl, ethyl-pyridine carboxylic ether (Canzoneri a. Spica, G. 14, 443).

**Methyl-formamide**  $\text{HCONHMe}$ . (190°) S.G. 0.911. Formed by evaporating an aqueous solution of methylamine formate, and distilling the residue. Liquid, sol. water and alcohol, insol. ether. Decomposed by alkalis and acids

into formic acid and  $\text{NMe}_3$ ; by  $\text{P}_2\text{O}_5$  into  $\text{CO}$ ,  $\text{HCN}$ , and  $\text{NH}_4\text{Me}$ ; and by  $\text{ZnCl}_2$  into  $\text{NH}_3$ ,  $\text{CO}$  and hydrocarbons (Linnemann, Sitz. W. [2] 60, 46).

**Ethyl-formamide**  $\text{HCONHEt}$ . (196°-197°). S.G. 0.952. Formed in the same way as the above. Liquid, sol. water and alcohol, insol. ether. Resembles the above in its reactions (Linnemann, *ibid.* 43).

**Diethyl-formamide**  $\text{HCONEt}_2$ . (175°-178°) (Linnemann, Sitz. W. [2] 60, 51); (178°) (Wallach a. Kamensky, A. 214, 240). S.G. 0.908 (L.). Prepared by distilling diethyl-amine formate (L.) (W. a. K.), or diethyl-oxamic acid (W. a. K.). Liquid, sol. water, but separated by  $\text{KHO}$  and  $\text{K}_2\text{CO}_3$ .

**Salt**.—( $\text{B}^+\text{HCl}$ )  $\text{PCl}_4$ ; yellow pp.

**Reactions**.—1. With acids, alkalis and  $\text{ZnCl}_2$  it behaves like the above compounds (Linnemann).—2.  $\text{PCl}_5$  gives  $\text{HCCl}_2\text{NEt}$ , which splits up thus  $2\text{HCCl}_2\text{NEt} = 3\text{HCl} + \text{C}_2\text{H}_4\text{Cl}_2\text{N}$ . The product is a base forming a salt ( $\text{B}^+\text{HCl}$ )  $\text{PCl}_4$ , and decomposed when heated with formation of pyrrole (Wallach a. Kamensky).

**Isopropyl-formamide**  $\text{HCONHPr}$ . (220°). From isopropyl-carbamine and  $\text{HCl}$  in the cold (Gautier, A. 149, 158).

**Phenyl-formamide**  $\text{HCONHC}_6\text{H}_5$ . *Formanilide* [46°].

**Formation**.—By distillation of equimolecular proportions of aniline and oxalic acid (Gerhardt, A. 60, 310; Hofmann, A. 142, 121),  $\text{C}_6\text{H}_5\text{O}_4 + \text{NH}_4\text{Ph} = \text{HCONHPh} + \text{CO}_2 + \text{H}_2\text{O}$ .

**Preparation**.—By heating aniline and formic acid (equimols.). The product is heated on a water-bath under reduced pressure to remove the water, then distilled at ordinary pressure up to 250°. The contents of the retort are then poured out (Tobias, B. 15, 2443, 2446; Wallach a. Wüsten, B. 16, 145).

**Properties**.—Long needles or four-sided prisms, m. sol. water, sol. alcohol; exhibits phenomenon of superfusion.

**Reactions**.—1. Decomposed by dilute acids into aniline and formic acid.—2. Split up by concentrated  $\text{HCl}$  into benzonitrile  $\text{HCONHPh} = \text{PhCN} + \text{H}_2\text{O}$ .—3. If gaseous  $\text{HCl}$  is passed in at 100° the amide is decomposed into formic acid and diphenyl-formamidine  $\text{CHNPhNHPh}$ .—4. By conc.  $\text{H}_2\text{SO}_4$  it is decomposed into  $\text{CO}$  and amido-benzene p-sulphonic acid.—5. With zinc-dust it yields  $\text{CO}$ ,  $\text{CO}_2$ ,  $\text{H}_2$ , aniline and benzonitrile (Gasiorowski a. Merz, B. 18, 1002).—6. Heated with phenyl cyanate at 180° it yields phenyl-carbamine, di-phenyl-urea and  $\text{CO}$  (Kühn, B. 18, 1477).—7. Converted by alcoholic solutions of alkyl bromides (1 mol.) followed by alcoholic  $\text{KOH}$  (1 mol.) into alkyl-formanilides (Pictet a. Crépeux, B. 21, 1106).

**Sodium formanilide**  $\text{HCONNaPh}$  aq. Formed by adding conc. soda to formanilide (Hofmann). Glistening plates; v. sol. alcohol; decomposed by water (Tobias, B. 15, 2443).

**Nitroso-formanilide**  $\text{HCON(NO)Ph}$ . [39°]. Formed by passing nitrous acid into a cooled solution of formanilide in acetic acid. Yellowish-white needles, v. sol. water; readily decomposed.

**Methyl-formanilide**  $\text{HCONMePh}$  (P.); (258°) at 716 mm. (P. a. C.). S.G. 0.997. Formed from the hydrochloride of formido-ether and methyl aniline, the reaction being

as follows:  $\text{NH}_2\text{CHOEt} + \text{HCl} + \text{NHMePh} + \text{H}_2\text{O} = \text{HCONMePh} + \text{EtOH} + \text{NH}_4\text{Cl}$  (Pinner, B. 16, 1652; P. A. C.).

*Ethyl-formanilide*  $\text{H.CO.NPhEt}$ . (258° i.v.) at 728 mm. S.G.  $\frac{1}{4}$  1.088.

*Propyl-formanilide*  $\text{H.CO.NPhPr}$ . (267° i.v.) at 787 mm. S.G.  $\frac{1}{4}$  1.044.

*Isopropyl-formanilide*  $\text{H.CO.NPhPr}$ . (268° i.v.) at 720 mm.

*Isobutyl-formanilide*  $\text{H.CO.NPh.C}_4\text{H}_9$ . (274° i.v.) at 731 mm.

*Isoamyl-formanilide*  $\text{H.CO.NPh.C}_5\text{H}_{11}$ . (286° i.v.) at 728 mm. S.G.  $\frac{1}{4}$  1.004.

*Phenyl-formanilide*  $\text{HCONPh}$ . Di-phenyl-formamide. [78°-74°]. [210°-220° in vacuo]. Formed from diphenylamine and formic or oxalic acid. When heated with  $\text{ZnCl}_2$  yields acridine (Willm. a. Girard, B. 8, 1196).

*Formo-o-toluide*  $\text{HCONHC}_6\text{H}_4\text{Me}$ . [58°] (Tobias, B. 15, 2448); [50.5°-57.6°] (Ladenburg, B. 10, 1129). (288°) (L.). Formed from o-toluidine and formic acid. Glistening leaflets, v. sol. alcohol. Decomposed into its constituents by dilute sulphuric acid. Heated for some time at its boiling-point it yields o-toluidine, methyl-ditolylamine, CO, and  $\text{CO}_2$ . Sodium derivative  $\text{HCONaC}_6\text{H}_4\text{Me}$  aq.

*Formo-p-toluide*. [45°] (Hübner, A. 209, 372); [52°] (Tobias, B. 15, 2446). Formed (1) as the above (T.); (2) by heating p-toluidine oxalate (H.). Long needles, v. sol. water, and alcohol. Converted into the nitrile of p-toluidic acid when heated with zinc-dust (B. 18, 1002).

*Formo-m-xylide*. [113°-114°]. Glistening needles or leaflets, v. sol. alcohol and ether (Gasiorowski a. Merz, B. 18, 1011).

*Formδ-cumide*  $\text{HCONHC}_6\text{H}_4\text{Me}$ . [121°]. Needles v. sl. sol. water, sol. alcohol and ether (Senier, C. J. 47, 768).

*Formo-isobutyl-o-toluide*  $\text{HCONHC}_6\text{H}_4\text{MeCH}_2\text{Pr}$  [1:2:4]. [105°]. Colourless tables, v. sl. sol. water, sol. alcohol and ether (Efront, B. 17, 2347).

*Formonaphthalides* v. NAPHTHYLAMINES.

*Formopiperidide* v. PIPERIDINE.

V. H. V.

**FORMIC ALDEHYDE**  $\text{CH}_2\text{O}$ . *Oxymethylene*. Mol. w. 80 (observed by Raoult's method: 84, Tollens a. Mayer, B. 21, 1566).

**Formation**.—1. By passing a current of air, charged with vapour of methyl alcohol, over a glowing spiral of platinum wire or over platinised asbestos; if the escaping gases are passed through a Liebig's condenser a solution of formic aldehyde in methyl alcohol will collect in the receiver (Hofmann, Pr. 16, 156; cf. Volhard, A. 176, 126; Kablonkoff, Bl. [3] 38, 379). When platinum foil at 55° is used the yield is 12 p.c. (Tollens, L. V. 29, 355; C. J. 46, 293). Red-hot oxide of iron or copper may be used instead of platinum (Loew, J. pr. [2] 38, 322; Tollens, B. 19, 2138).—2. By decomposing chloro-methyl acetate (2 pts.) with water (1 pt.) by heating for 30 minutes to 100° (Michael, Am. 1, 418).—3. Formed in small quantities by the action of ozone on coal-gas (Macquenne, Bl. [2] 87, 298).—4. In small quantity, together with formic acid and  $\text{H}_2$ , by the action of the silent electric discharge on a mixture of hydrogen and  $\text{CO}_2$  (Brodie, Fr. 2, 172).—5. When a mixture of methylal

$\text{CH}_2(\text{OMe})_2$  and  $\text{H}_2\text{SO}_4$  is warmed, formic aldehyde is given off, but it quickly polymerises giving a sublimate of its solid modification.—6. By heating ethylene with oxygen at 400° (Schützenberger, Bl. [2] 31, 482).—7. In the incomplete combustion of nitric ether (Pratesi, G. 14, 221).

**Properties**.—Formic aldehyde is only known in solution; by freezing the solution and removing the ice an aqueous solution may be concentrated until it contains 10 p.c. of the aldehyde (Hofmann, B. 11, 1685; cf. Tollens, B. 15, 1629; 16, 917). The aqueous solution is pungent; it reduces ammoniacal  $\text{AgNO}_3$ , forming, when gently warmed, a silver mirror. When warmed with aqueous KOH it gives a brownish oil and an odour like that accompanying aldehyde-resin. Dilute aqueous NaOH gives formic acid and MeOH. After treating the solution with  $\text{H}_2\text{S}$  and heating the resulting liquid with conc.  $\text{HCl}$  aq. it solidifies on cooling to a dazzling white mass of felted needles consisting of  $(\text{CH}_2\text{S})_n$ . When evaporated with ammonia or ammonium carbonate it leaves a residue of hexamethylenamine, by weighing which the amount of formic aldehyde in the solution may be determined (Loew, J. pr. [2] 33, 322; cf. Legler, B. 16, 1333). A solution of formic aldehyde deposits after some time insoluble formic paraldehyde or tri-oxy-methylene.

**Reactions**.—1. Readily condensed by strong bases, to a less extent by salts with alkaline reaction. Calcined  $\text{MgO}$  has no action.  $\text{BaH}_2\text{O}_2\text{Aq}$  gives formic acid and methyl alcohol; the  $\text{BaH}_2\text{O}_2$  is, however, soon neutralised and ceases to act.  $\text{CaH}_2\text{O}_2\text{Aq}$ ,  $\text{MgH}_2\text{O}_2\text{Aq}$ , Fe, Pb, PbO, many Pb salts,  $\text{NEt}_3\text{OH}$ , and many organic bases give rise to formose or methylenitan  $\text{C}_6\text{H}_{10}\text{O}_4$ . By boiling a 7 p.c. solution with tin a body resembling formose, called (β)-formose, is formed.  $\text{MgH}_2\text{O}_2\text{Aq}$  at about 100° gives at least two sugars, one of which yields an osazone in yellow needles [152°]. None of these sugars ferment with yeast. NaCl has no action alone, but increases the activity of  $\text{CaH}_2\text{O}_2\text{Aq}$ , whilst NaAcO,  $\text{KNO}_3$ , and much Cu, Fe, or Sn diminish it (O. Loew, B. 21, 270; J. pr. [2] 33, 321; 34, 51; Wehmer a. Tollens, A. 243, 340).—2. Readily condenses with primary amines:  $\text{CH}_2\text{O} + \text{H}_2\text{NR} = \text{H}_2\text{O} + \text{CH}_2\text{NR}$ . Thus methylaniline, aniline, o-toluidine, and p-toluidine give methylene-methyl-amine (c. 207°), phenyl-methylene-amine  $\text{C}_6\text{H}_5\text{N:CH}_2$  [138°], o-tolyl-methylene-amine  $\text{C}_6\text{H}_4\text{MeN:CH}_2$ , and p-tolyl-methylene-amine [c. 122°] respectively (Kolottoff, Bl. [2] 45, 253; Tollens, B. 17, 657; Wellington a. Tollens, B. 18, 3309). These formulae ought, perhaps, to be doubled. Primary and secondary bases also give compounds of the form  $\text{CH}_2(\text{NHR})_2$  and  $\text{CH}_2(\text{NRR}')_2$ , thus: aniline and di-ethyl-amine give di-phenyl-methylene-diamine  $\text{CH}_2(\text{NHPH})_2$  [49°], and methylene-tetra-ethyl-diamine  $\text{CH}_2(\text{NEt})_4$  [167°] respectively (Pratesi, G. 14, 358; Kolottoff, Bl. [2] 43, 112; Ehrenberg, J. pr. [9] 36, 118). In these condensations with bases the paraldehyde may be used.—3. By boiling with a solution of ammonium chloride it is converted into NMe, and  $\text{CO}_2$  (Fiechl, B. 21, 3117). 4. By heating a 16 p.c. solution of formic aldehyde with ammonium sulphate on the water-bath  $\text{CO}_2$  is given off and the sulphates of mono-, di-, and tri-methylamine are formed. If methyl-

amine or dimethylamine hydrochloride be substituted for the ammonium sulphate trimethylamine is formed in both cases.—5. Trimethylamine hydrochloride does not act on formic aldehyde (Plochl, B. 21, 2117).

**Phenylhydrazide**  $\text{CH}_2\text{N}_2\text{H}_2\text{O}$  (?) [184°]. Colourless trimetric tables. Formed by adding phenyl-hydrazine to a solution of formic aldehyde (Wallington a. Tollens, B. 18, 8300).

**Formic paraldehyde**  $(\text{CH}_2\text{O})_3$ ? **Tri-oxy-methylene**. [152°].

**Formation**.—1. By spontaneous polymerisation of formic aldehyde in aqueous solution.—2. From methylene iodide by the action of  $\text{Ag}_2\text{O}$  or of silver oxalate. Also from methylene acetate by heating with water at 100° (Butlerow, A. 111, 242).—3. By heating calcium glycolate (1 pt.) with  $\text{H}_2\text{SO}_4$  (7 pts.) at 175° (Heintz, A. 138, 43); and in small quantity by heating glycolic acid at 220° (Heintz, J. 1861, 444).—4. By the action of water on chloro- or di-chloro-dimethyl oxide ( $\text{MeO.CH}_2\text{Cl}$  or  $\text{MeO.CHCl}_2$ ) (Friedel, C. R. 84, 247; Butlerow, Z. 1865, 619).—5. By electrolysis of a solution of glycol, glycerin, mannite, or glucose in dilute  $\text{H}_2\text{SO}_4$  (Renard, A. Ch. [5] 17, 303).

**Properties**.—Crystalline mass. Even below 100° it sublimates, but its melting-point is thereby raised from 152° to 172° (Tollens, B. 16, 919). Formic paraldehyde is converted on vaporisation into  $\text{CH}_2\text{O}$  (V.D. 1.06). It is insol. water, alcohol, and ether, but dissolves in cold aqueous  $\text{NaOH}$  or baryta. It is also dissolved by heating with water at 100°, being thereby converted into ordinary formic aldehyde (Tollens a. Mayer, B. 21, 1571). When hot it has a pungent odour. Heating with a trace of  $\text{H}_2\text{SO}_4$  in a sealed tube at 115° converts it into '(a)-tri-oxy-methylene'  $\text{C}_3\text{H}_4\text{O}_3$ , [61°], V.D. 44.9 ( $\text{H} = 1$ ); (a)-tri-oxy-methylene is sol. water, alcohol, and ether, and reduces ammoniacal  $\text{AgNO}_3$  in presence of  $\text{KOH}$  (Pratesi, G. 14, 140). When a solution of formic aldehyde is evaporated over  $\text{H}_2\text{SO}_4$ , there is formed a soft substance, v. sol. water, whose molecular weight, determined by Raoult's method, corresponds to the formula  $(\text{CH}_2\text{O})_3$  (Tollens a. Mayer, B. 21, 3503).

**Reactions**.—1.  $\text{PI}_3$  gives methylene iodide.—2. Boiling with alcohol and some  $\text{H}_2\text{SO}_4$  gives  $\text{CH}_3(\text{OEt})_2$ .—3. Boiling lime-water gives formose (methyleneitan) (Butlerow, A. 120, 295).—4. Heating with water and  $\text{MgO}$  at 180°, and afterwards at 220°, gives formic acid and  $\text{MeOH}$ .—5.  $\text{Ag}_2\text{O}$  gives a silver mirror and formic acid (Heintz, A. 138, 223).—6. Conc.  $\text{HClAq}$  at 100° gives  $\text{MeCl}$  and formic acid (Tischtschenko, J. R. 15, 321).—7. Dry  $\text{NH}_3$  forms hexamethylene-tetramine  $\text{C}_6\text{H}_{12}\text{N}_4$ , which crystallises from alcohol in rhombohedra; v. sol. water; al. sol. cold alcohol, almost insol. ether (Butlerow, A. 115, 322).—8. **Ethylamine** gives  $(\text{CH}_3)(\text{NEt}_2)$ ; di-ethylamine forms  $\text{CH}_3(\text{NEt}_2)_2$ ; tri-ethylamine has no action. Other bases act in like manner when heated with formic paraldehyde (Ehrenberg, J. pr. [2] 86, 117).—9. **Chlorine** in sunlight forms  $\text{COCl}_2$  and  $\text{HCl}$  (Tischtschenko, J. R. 1887, 479). **Bromine** gives  $(\text{CH}_2\text{Br})_3\text{O}$ , formic acid,  $\text{HBr}$ , methyl bromide,  $\text{CO}$ , and  $\text{CO}_2$ .—10.  $\text{ZnEt}_2$ , followed by water, gives propyl alcohol.  $\text{ZnPr}_2$  gives, in like manner, butyl alcohol (Tischtschenko, B. [2]

48, 112).—11. By heating with dilute  $\text{HCl}$  it is resolved into formic acid and  $\text{MeOH}$  or  $\text{MeCl}$  (T.). Dry  $\text{HCl}$  slowly forms  $(\text{CH}_2\text{Cl})_3\text{O}$  (102°–108°).—12. Dry  $\text{HI}$  is absorbed with formation of water and  $(\text{CH}_2\text{I})_3\text{O}$  (219°) (Tischtschenko, J. R. 1887, 464).—13. Dry  $\text{HBr}$  acts in like manner, forming  $(\text{CH}_2\text{Br})_3\text{O}$  (150°). This body is a pungent fuming oil, sol. ether, benzene, and acetone. Water decomposes it into  $\text{Me}_2\text{O}$  and  $\text{HBr}$ .—14. Aqueous  $\text{HBr}$  and formic paraldehyde at 140° give methyl bromide and formic acid.

**Formic orthaldehyde**  $\text{CH}_2(\text{OH})_2$ .

**Acetyl derivative**  $\text{CH}_3(\text{OAc})_2$ . **Methylene acetate**. (170°). Formed by the action of methylene iodide on silver acetate (Butlerow, A. 107, 111; 111, 242; Beyer, B. 5, 1094; 6, 220). Formed also by treating  $\text{CH}_3\text{OAc}$  with  $\text{KOAc}$  (Henry, B. 6, 739). Heavy liquid, sol. cold water, but when heated in a sealed tube for twenty hours at 100°, with a quantity of water insufficient to dissolve it in the cold, it is resolved into acetic acid and formic paraldehyde.

**Acetyl derivative of the Methyl ether**  $\text{CH}_3(\text{OMe})(\text{OAc})$ . (118°). From  $\text{CH}_3\text{O.CH}_2\text{Cl}$  and  $\text{KOAc}$  (Friedel, B. 10, 492). Decomposed by alkalis into water,  $\text{HOAc}$ , and formic paraldehyde.

**Methyl ether**  $\text{CH}_3(\text{OMe})_2$ . **Methylene dimethyl di-oxide**. **Methylal**. Mol. w. 76. (42°). S.G.  $\frac{4}{4}$  8604 (Brühl, A. 203, 12). Critical temperature: 224°. S. 28. H.C.p. 433,900 (Berthelot a. Ogier, A. Ch. [5] 23, 201). H.F.p. 88,240. H.E.v. 85,920 (Th.). Formed by distilling a mixture of water (3 pts.),  $\text{H}_2\text{SO}_4$  (3 pts.), methyl alcohol (2 pts.), and  $\text{MnO}_2$  (2 pts.) (Kane, A. 19, 175; Malaguti, A. 32, 55). Formed also by electrolysis of methyl alcohol (100 pts.) acidified with  $\text{H}_2\text{SO}_4$  (1 pt.) diluted with water (4 pts.) (Renard, A. Ch. [5] 17, 291). Methylal is a liquid. A dose of 5g. to 8g. produces a hypnotic effect (Mairet a. Combemale, C. R. 104, 1022).

**Reactions**.—1. Methylal is employed by Baeyer (B. 5, 1094; 6, 220) as more convenient than formic aldehyde in obtaining derivatives of methane by elimination of water between that aldehyde and aromatic hydrocarbons. Thus, if a mixture of benzene (120 pts.), methylal (40 pts.), and acetic acid (400 pts.) be treated with a mixture of equal parts of  $\text{HOAc}$  and  $\text{H}_2\text{SO}_4$ , till the greater part of the benzene has separated, and the whole be then left for twenty-four hours, it will be found, after mixing with cold  $\text{H}_2\text{SO}_4$  (2000 pts.), diluting after some hours with water, and shaking up with ether, that di-phenyl-methane has been formed:  $\text{CH}_3(\text{OMe})_2 + 2\text{C}_6\text{H}_6 = \text{CH}_2(\text{C}_6\text{H}_5)_2 + 2\text{HOMe}$ . Methylal may serve as a nourishment for algae; under these conditions they develop cellulose, but they only develop starch in daylight (Loew a. Bokorny, J. pr. [2] 86, 272).

**Ethyl ether**  $\text{CH}_3(\text{OEt})_2$ . (89° cor.) (G.); (88°) (H.); (88°) (P.). S.G.  $\frac{17}{17}$  826 (H.); 2.851 (G.); 2.840 (P.). V.D. 8.44 (H.). Prepared by the action of sodium on a solution of methylene chloride in absolute alcohol (Greene, A. C. J. 1, 522; B. [2] 45, 164; C. R. 89, 1077). Formed also by treating  $\text{CH}_2\text{I}_2$  with  $\text{NaOEt}$  (Henry, B. [2] 45, 837; C. R. 101, 599); and by distilling formic paraldehyde with alcohol and a little  $\text{H}_2\text{SO}_4$  (Pratesi, G. 18, 518). Mobile liquid, with

# FORMIC ALDEHYDE.

811

agreeable odour like mint. Sl. sol. water, insol. conc.  $\text{CaCl}_2$  aq.

*Di-propyl ether*  $\text{CH}_3(\text{OPr})_2$  (137°). S.G. 22-835 (Arnhold, A. 240, 139).

*Di-isopropyl ether*  $\text{CH}_3(\text{OPr})_2$  (118°). S.G. 22-881.

*Di-isobutyl ether*  $\text{CH}_3(\text{OCH}_2\text{Pr})_2$  (164°). S.G. 22-825.

*Di-isoamyl ether*  $\text{CH}_3(\text{OC}_4\text{H}_9)_2$  (207°). S.G. 22-835.

*Di-octyl ether*  $\text{CH}_3(\text{OC}_8\text{H}_{17})_2$  (above 360°). S.G. 22-846.

*Di-benzyl ether*  $\text{CH}_3(\text{OCH}_2\text{Ph})_2$  (above 360°). S.G. 22-1053.

*Di-phenyl ether*  $\text{CH}_3(\text{OPh})_2$  (299°). S.G. 22-1092.

*Di-o-tolyl ether*  $\text{CH}_3(\text{OC}_6\text{H}_4\text{Me})_2$  [32°]. S.G. 22-1019. From methylene chloride and the sodium derivative of *o*-cresol (Arnhold, A. 240, 202).

*Di-m-tolyl ether*  $\text{CH}_3(\text{OC}_6\text{H}_4\text{Me})_2$  [45°]. (above 360°). S.G. 22-1052.

*Di-p-tolyl ether*  $\text{CH}_3(\text{OC}_6\text{H}_4\text{Me})_2$  [40°]. (above 360°). S.G. 22-1034.

*Di-thymyl ether*  $\text{CH}_3(\text{OC}_{10}\text{H}_{19})_2$  [86°]. (above 360°). S.G. 22-979.

Formose  $\text{C}_6\text{H}_{12}\text{O}_6$  dried at 90°. From formic aldehyde by adding cold milk of lime to a 4 p.c. solution, filtering, and leaving the filtrate to stand for some days (Loew, J. pr. [2] 33, 828).

*Properties*.—Syrup, sl. sol. alcohol, insol. ether. Sweet taste. 0.55 g. reduce 10 c.c. of Fehling's solution. By heating at 100°-120° for five days it becomes 'methylenitan'  $\text{C}_6\text{H}_{12}\text{O}_6$ , which has a bitter taste, and has only one-fourth its reducing power. Prevents the precipitation of cupric sulphate by potash. Hot conc. HCl turns it brown, as it does cane-sugar and levulose, but not glucose; the filtrate can reduce Fehling's solution (Wehmer, B. 20, 2614). Cold milk of lime slowly destroys it. Warm alkaline solutions of picric acid are turned red, and indigo is bleached, as by glucose and levulose. Warmed with conc. alcoholic resorcin and HCl a ruby-red colour is produced; cane-sugar, levulose and glucose give paler colours (Ihl & Pechmann, C. C. 1885, 761). Aqueous pyrogallol and HCl act similarly. Conc. alcoholic diphenylamine and HCl give a brownish-violet colour on warming. Schiff's reaction gives no colour with formose. Formose can undergo lactic but not alcoholic fermentation. It is, however, accompanied by a sugar that can undergo alcoholic fermentation (Loew, B. 22, 470). Alkaline diazobenzene sulphonic acid gives a red colour, as with carbohydrates and aldehydes. Phenyl hydrazine reacts thus:  $\text{C}_6\text{H}_{12}\text{O}_6 + 2\text{N}_2\text{H}_5\text{Ph} - \text{C}_6\text{H}_5\text{N}_3\text{O}_6 + 3\text{H}_2\text{O}$ . The product crystallises from dilute alcohol in slender needles. Plants which readily produce starch from glucose, cane-sugar, mannite, and glycerin do not produce it from formose (W.). When a solution of formose (10 g.) in water (1 litre) is boiled for a long time, the product extracted with chloroform, and the residue after evaporation of the chloroform treated with alcohol, aniline, and a little HCl, an intense red colour characteristic of furfural is produced. This reaction is characteristic of sugars. In fact, when formose is digested with 1 p.c. sulphuric acid at 100°, more furfural is formed than from other sugars (Loew,

B. 20, 3039). Loew maintains that formose is well characterised as a sugar. E. Fischer (B. 21, 991) points out that the product of the action of lime-water on formic aldehyde is a mixture of three or more aldehydic or ketonic alcohols, one of them being the artificial sugar from acrolein, acrose, characterised by its phenyl-hydrazide [317°] (Fischer & Passmore, B. 22, 359).

Methylenitan  $\text{C}_6\text{H}_{12}\text{O}_6$  (?). Obtained by the action of lime water on formic aldehyde or paraldehyde (Butlerow, A. 120, 296; C. R. 53, 145; Loew, J. pr. [2] 33, 821; 37, 203; Wehmer & Tollens, A. 243, 340). The product is saturated with  $\text{CO}_2$ , filtered, and evaporated. Formed also by the action of heat upon formose. Amorphous gummy mass. Has a bitter taste. Does not react with phenyl-hydrazine. Sol. alcohol. When boiled with Fehling's solution it reduces only one-fourth as much  $\text{CuO}$  as glucose does. After boiling with dilute acids the reducing power is the same. It is optically inactive. It does not undergo alcoholic fermentation. When boiled for a long time with dilute  $\text{H}_2\text{SO}_4$  it gives formic and acetic, but no levulinic acids. It has no action on cold  $\text{CaCO}_3$ , but dissolves it and gives off  $\text{CO}_2$  on heating. According to Loew (J. pr. [2] 33, 842), methylenitan  $\text{C}_6\text{H}_{12}\text{O}_6$  is the saccharin of formose, and may be got by heating formose with lime or baryta and water at 70°-100°.

Pseudoformose. Got by boiling formic aldehyde in 7 p.c. solution with tin (Loew, J. pr. [2] 34, 51). Resembles formose in most respects. Differs from formose (1) in giving orange, not violet, colouration, with resorcin, HCl, and alcohol; (2) 10 c.c. Fehling reduce 0.52 g.; (3) in forming the phenyl-hydrazine composed more quickly. Phenyl-hydrazine forms an osazone [123°]; when this body is heated for 80 hours in alcoholic solution at 100° its melting-point is found to have risen to 148°.

( $\beta$ )-Formose. Formed when a 1 p.c. solution of formic aldehyde is boiled for 5 hours with much tin (Loew, B. 21, 270). Thick, sweet, non-fermentable syrup; does not become brown at 100°. It yields humous substances with HCl. Turned brown by potash. Its solution in alcoholic HCl yields a wine-red colour with resorcin and a steel blue colour with diphenylamine. 10 c.c. of Fehling's solution are reduced by 0.739 of ( $\beta$ )-formose. Its phenyl-hydrazide or 'osazone'  $\text{C}_{18}\text{H}_{22}\text{N}_4\text{O}_6$  crystallises in small yellow needles [148°].

Two other formoses or 'non-fermentable' sugars are said by Loew to be formed by heating formic aldehyde, 3 pts., at 100° with an aqueous solution (1000 pts.) of magnesia obtained by treating a 7 p.c. solution of  $\text{MgSO}_4$  with litharge. One of these gives with phenyl hydrazine an osazone crystallising from benzene in yellow needles [152°].

Isomeride of Formose (?). In the electrolysis of glycerin (30 vols.) acidified with  $\text{H}_2\text{SO}_4$  (3 vols.), diluted with water (20 vols.), there is formed, together with formic paraldehyde, a syrupy isomeride of formic aldehyde. It blackens at 90°, giving an odour of burnt sugar. It is v. c. sol. alcohol and water, is unfermentable, reduces Fehling's solution and ammoniacal  $\text{AgNO}_3$ . Its solution is ppd. by ammoniacal lead acetate but not by lead subacetate.  $\text{HNO}_3$  oxidises it to oxalic acid. Baryta added to its alcoholic solution

tion ppts.  $(C_2H_5O)_2, 3BaO$ . This body is perhaps identical with formose or methylenitan.

**FORM-IMID-AMIDE** v. **FORMAMIDINE**.

**Form-ethyl-imid-ethyl-amide** v. **2-DI-ETHYL-FORMAMIDINE**.

**FORM-IMID-DI-ETHYL-AMIDE** v. **2-DI-ETHYL-FORMAMIDINE**.

**FORM-IMIDO-ETHER**  $C_2H_5NO$  i.e.

$NH:CH.OEt$  (80°)? Hydrochloride  $B'HCl$ . Formed by the action of gaseous  $HCl$  (2 mols.) on dry  $H_2O$  (1 mol.) mixed with alcohol (1 mol.) in a freezing mixture (Pinner, *B.* 16, 854, 1644). Glittering prisms. Very unstable, decomposing on keeping with formation of  $NH_4Cl$ . With alcohol it gives  $NH_4Cl$  and orthoformic ether.

**Reactions.**—1. Decomposed by heat into  $EtCl$ , formic ether, and the hydrochloride of formamidine.—2.  $KOH$  separates a small quantity of an oil (80°).—3. Alcoholic  $NH_3$  in the cold gives formamidine.—4. Dimethylamine forms  $NH:CH.NMe_2$ .—5. Methyl-aniline forms  $C_6H_5NM_2(CHO)$ .—6. Phenyl-hydrazine forms  $C_6H_5N_2$ .—7. An alcoholic solution of  $NET_3$  slowly forms a base  $C_2H_5N_3$ , which forms a platinumchloride  $B'H.PtCl_4$  [153°] crystallising in flat prisms (Pinner, *B.* 16, 1650; 17, 180).—8.  $NaOAc$  and  $Ac_2O$  give  $NH:CH.OAc$  [70°] which crystallises from ether in short prisms, v. sol. ordinary menstrua.

**Formimido-methylene ether**  $(NH:CHO)_2CH_2$ . Hydrochloride  $B'^2HCl$ . Formed by passing  $HCl$  into glycol (1 mol.) and  $H_2O$  (2 mols.) diluted with ether at 0° (Pinner).

**FORMINS.** Formyl derivatives of polyhydric alcohols. They are described under the alcohols from which they are derived.

**FORM-METHYL-IMID-METHYL-AMIDE** v. **DI-METHYL-FORMAMIDINE**.

**FORMO-CUMIDIDE** v. **CUMIDINE**. Formyl derivatives of bases are described for the most part both under **FORMO ACID** and under the bases.

**FORMOGUANAMINE**  $C_4H_7N_3$ , [above 350°]. Formed together with  $CO_2$ , ammonia,  $CO$ , and water by heating guanidine formate at 200° (Nencki, *B.* 7, 1584). Trimetric needles, with feeble alkaline reaction. V. sol. hot water, sl. sol. alcohol. May be sublimed with partial carbonisation.— $B'HCl$ : trimetric plates.— $B'H.PtCl_4$ .— $B'HNO_2$ : needles or prisms.— $B'H_2C_2O_4$ : granular-crystalline pp., insol. cold, sl. sol. hot, water.

**FORMO-NAPHTHALIDE** v. **Formyl derivatives of NAPHTHYLAMINE**.

**FORMOSE** v. **FORMIC ALDEHYDE**.

**FORMO-TOLUIDE** v. **Formyl derivative of TOLUIDINE**.

**FORM-PHENYL-IMID-PHENYL-AMIDE** v. **2-PHENYL-FORMAMIDINE**.

**FORMULE.** Symbols have been in use in chemistry from the earliest period of the science, but as knowledge has grown their meaning has become deeper and deeper; and the difference between the significance of the earliest symbols and of the elaborate chemical formulae of the present is as great as the difference between the knowledge of chemical phenomena possessed by the earliest chemists, and that possessed by the chemists of to-day. The first attempt of any importance to represent more than the name of a substance was that of Hassenegratz and Adel

in 1787. These chemists represented all metals by circles, in which were written the first letters of the Latin names thus: Copper  $\odot$ , lead  $\gamma$ . All alkalis and alkaline earths were represented by triangles placed in different positions; oxygen by a horizontal line, &c., &c. The composition of compound substances was represented by placing side by side the symbols of the elementary substances contained in them. This system was recommended by Lavoisier, Berthollet, and Fourcroy in a report made by them to the French Academy in 1787, but it was not generally accepted. The next suggestion of importance was made by Dalton in 1808. He represented the atoms of the elements by circles, and distinguished them by various additions. Thus, hydrogen was represented by  $\odot$ , oxygen by  $\odot$ , nitrogen by  $\odot$ , sulphur by  $\oplus$ , &c. The composition of compounds was represented by placing side by side the symbols of the elements of which the compounds were made up. Thus, water was represented by the symbol  $\odot\odot$ , ammonia by  $\odot\odot$ , nitrous oxide by  $\odot\odot$ , &c. The present system of symbols was introduced by Berzelius. They are based upon the atomic theory, each symbol of an element being intended to represent an atom of an element. As is well known, the symbol of an element is the first letter, or the first letter and some other letter, of the name of the element. In many cases the symbol is derived from the Latin name of the element.

The composition of compounds was represented by writing side by side the symbols of the elements which were in combination. The symbol of a compound was thus an expression of the view held regarding the structure of the compound. As H represents an atom of hydrogen and O an atom of oxygen, the symbol  $HO$  for water meant that what was then called an atom of water was made up of an atom of hydrogen and an atom of oxygen. So far as it represented that water is made up of hydrogen and oxygen in the proportion by weight of 1 pt. of the former to 8 pts. of the latter, it represented a fact in regard to which there could be no dispute. But when it was interpreted as meaning that an atom of hydrogen is in combination with an atom of oxygen, a definite theory in regard to the structure of matter was involved. The difficulties in the way of determining atomic weights have been referred to in previous articles (v. **ATOMIC AND MOLECULAR WEIGHTS**, vol. i.). Until the introduction of the method of Avogadro, and that of Dulong and Petit, for the determination of atomic weights, there was much difference of opinion in regard to the figures to be adopted, and, therefore, the symbols did not always represent the same thing. At the present time most chemists are agreed as to the system of atomic weights, and the symbols of the elements now in use are intended to represent atomic weights as determined mainly by the methods of Avogadro, and Dulong and Petit. These atomic weights are strongly confirmed by the discovery of the periodic law, which would be meaningless with any other system than that now generally adopted. There are some chemists in France who refuse to accept the atomic weights, and the symbols used by them do not mean the same thing as those used by other chemists.

The chemical formula of a compound is intended primarily to represent the quantitative composition of the compound. In terms of the accepted theory of the structure of matter, it is intended to tell what atoms, and how many, are combined to make the smallest particle of the compound which exhibits the properties of that compound. This smallest particle of the compound is called a molecule. The formula then is intended to represent a molecule. In the case of gaseous compounds, or of compounds which can be converted into gases without undergoing decomposition, we have, of course, the means of determining the relative weights of the molecules on the basis of Avogadro's law. The methods, then, which are involved in the determination of molecular formulæ are these: (1) the substance must be analysed; (2) the molecular weight must be determined. The formula must express the results of both determinations. To show how this is done one example will suffice. Let it be desired to determine the molecular formula of water. The analysis shows that it consists of hydrogen and oxygen in the proportion of 1 pt. by weight of the former to 8 pts. by weight of the latter. This is a fact involving no speculation whatever, and any formula adopted must be in accordance with this fact. The next step is to determine the specific gravity of water vapour. As compared with air its specific gravity is 0.623. This gives the relative weight of the molecule of water, and, adopting the usual standard, it shows the molecular weight of water to be 18. The atomic weight of oxygen has been shown to be 16, if that of hydrogen is 1, so that we now have all the data for writing the molecular formula. A molecule which consists of hydrogen and oxygen in the proportions mentioned above, and the weight of which is 18 in terms of an accepted unit weight, must contain 2 atoms of hydrogen and 1 atom of oxygen. This is expressed by the formula  $H_2O$ . A molecule thus made up weighs 18 times as much as an atom of hydrogen, or the molecular weight of the compound is 18, the 18 pts. being made up of 16 pts. of oxygen and 2 pts. of hydrogen. Thus the formula expresses the results of the analysis and of the determination of the specific gravity of water vapour, and these results are interpreted in terms of the molecular and atomic theory and the law of Avogadro. This is true of every formula of a gaseous substance.

As regards the molecular formulæ of liquid and solid substances we know but little. Many facts indicate that the molecules of liquids and solids are much more complex than those of gases, but no altogether satisfactory method has yet been discovered for determining the molecular weights of such substances. Among the facts which lead to the conclusion that the molecules of liquids and solids are complex may be mentioned, the not uncommon observation that just above the boiling-point vapours have a greater specific gravity than at a higher temperature. It is not probable that the molecules of liquid and solid sulphur contain less than six atoms. The existence of allotropic modifications of the solid elements sulphur and phosphorus is probably best explained by assuming that the molecules of the allotropic modifications contain different numbers of atoms.

An attempt has been made to establish a method for the determination of the molecular weights of solids by means of observations upon the freezing-points of solutions. Many observations have shown that there is a definite connexion between the molecular weights of solids and the freezing-points of their solutions, and the law expressing this connexion has been stated provisionally by Raoult, who finds that quantities of chemically similar compounds proportional to the molecular weights of these compounds generally produce equal lowerings of the freezing-points of water and other solvents. There seem, however, to be exceptions to this law.

The formulæ of liquids and solids are not molecular formulæ in the sense in which the formula of a gas of which the specific gravity is known is. Even the formula of water  $H_2O$  is strictly applicable only to water in the state of vapour. Whether on condensing to the form of the liquid several of the simple molecules unite to form more complex molecules, we cannot positively say, but probably they do. So also, when the liquid water becomes solid ice, it is not improbable that a still further union of molecules takes place.

If we consider the case of a solid compound which cannot be converted into vapour, our formula plainly cannot express the molecular weight at all. In writing the formula of sodium chloride  $NaCl$ , we do so because that is the simplest formula which will express the fact that the compound consists of 23 pts. of sodium and 35.5 pts. of chlorine. But the formulæ  $Na_2Cl_2$ ,  $Na_3Cl_3$ ,  $Na_4Cl_4$ , &c., express the results of analyses just as well, and at the same time are probably nearer the truth than the simpler one. The time may come when it will be necessary to express the molecular weights of solids and liquids, as well as of gases, in chemical formulæ. At present, so far as the facts which we generally have to express in our formulæ are concerned, it is not a matter of any special importance whether we know the true molecular weights or not. Indeed, it is not improbable that, even though the molecules of solids and liquids are comparatively complex, they are reduced to the simple forms under the conditions under which chemical action takes place. Thus, when a solid or a liquid is dissolved, probably the complex molecules of which it is composed are broken down and become simple in the dilute solutions. This would be in accordance with the fact that solutions act readily upon one another; and it is in accordance with recent work on the electrolytic conduction of salts in solution (*v. PHYSICAL METHODS*).

From what has been said it is clear that we have to distinguish between *molecular formulæ* and *composition-formulæ*, the former being applicable only in cases of gases, the latter being used in cases in which molecular formulæ cannot be written owing to a lack of knowledge of the facts. In both these kinds of formulæ the atomic theory is involved.

But chemists have come to express much more by their formulæ than the composition and the molecular weights of compounds. They express views in regard to the arrangement or relations of the parts which are in combination. Neither the atomic theory nor the hypothesis of

Avogadro has any direct connexion with the arrangement of the parts constituting a molecule. All that the former claims is that, when chemical action takes place, it takes place between certain minute particles called atoms; that when an act of chemical combination occurs two or more atoms combine. The hypothesis of Avogadro goes one step further. According to it the particles formed by the combination of atoms, i.e. the molecules, bear such relations to one another that they always require the same space for the same number, no matter what their composition may be.

As a result of the study of the chemical changes of compounds, however, chemists have come to hold certain views in regard to the relations of the parts, or atoms, which enter into the composition of molecules. Formulæ which express these views are called in general *rational formulæ*, or *constitutional* or *structural formulæ*. Rational formulæ have been in use in chemistry for a long time. Lavoisier's studies on oxygen and the phenomena of combustion led him to ascribe to that element a degree of supreme importance. According to him the oxygen was the chief constituent of every compound. It was oxygen which made acids what they are, and oxygen which made bases what they are. When a salt is formed the acid and base unite, and the salt consists of the two parts in combination. Thus potassium nitrate is  $\text{KONO}_2$ , sodium sulphate  $\text{NaO.SO}_2$ , &c. These formulæ not only express the composition of the compounds which they represent, they express the view that the salts consist of two parts, each of which contains oxygen. The same view was extended to other compounds, and the attempt was made to express the constitution of every compound in a similar way. The constitutional formulæ thus introduced were based upon the hypothesis of *dualism*. They were called *dualistic formulæ*. The dualistic view found support in a study of the action of the electric current on chemical compounds. As compounds are decomposed by the electric current into two parts, one going to the positive, the other to the negative, pole, the view that every compound consists of two parts was thus plainly strengthened. The introduction of the electro-chemical theory by Berzelius led to the general use of dualistic formulæ. These formulæ were intended to represent the electro-negative and the electro-positive constituent of each compound. For a long time these formulæ were used exclusively, and in some books even at the present day they are found, though many facts have been discovered which show that the electro-chemical theory is untenable—at least, in the form in which it was put forward by Berzelius (v. DUALISM).

Owing to the complexity of the compounds of carbon, and the fact that they readily undergo changes, the chief studies which have led to the views at present held have been made with regard to these compounds. At one time what was called the *theory of radicles* played an important part, and at this time every formula expressed the views of chemists regarding the particular radicle or radicles contained in a compound. These radicles were groups of atoms which could be transferred from one compound to another without undergoing change of composition. According to the *theory of conjugate compounds* (*Theorie*

*der gepaarten Verbindungen*), every complex compound is made up of some simple compound conjugated with a complex group. Thus aniline was regarded as made up of ammonia conjugated with a group  $\text{C}_6\text{H}_5$ , as represented in the formula  $\text{C}_6\text{H}_5.\text{NH}_3$ . The sulphonic acids were in the same way regarded as made up of sulphuric acid conjugated with various groups of carbon and hydrogen. Next came the *theory of types*, which regards all compounds as built according to a few plans. The general plans of all compounds were found in simple compounds like hydrochloric acid, water, ammonia, and marsh gas. In saying that alcohol, for example, belongs to the water type it was meant that it may be regarded as derived from water by the substitution of the group  $\text{C}_2\text{H}_5$  for a part of the hydrogen in water. The relation between the two was represented by the formulæ  $\begin{matrix} \text{H} \\ | \\ \text{H} \end{matrix} \text{O}$  and  $\begin{matrix} \text{C}_2\text{H}_5 \\ | \\ \text{H} \end{matrix} \text{O}$ . So, too, aniline was regarded as belonging to the ammonia type, and the relation between them was represented by the formulæ  $\begin{matrix} \text{H} \\ | \\ \text{H} \end{matrix} \text{N}$  and

$\begin{matrix} \text{C}_6\text{H}_5 \\ | \\ \text{H} \end{matrix} \text{N}$ . It will be seen that this method of clas-

sification or of expressing constitution involves the conception of substitution and, to some extent, the conception of radicles i.e. of complex groups playing the part of single atoms. The object of a typical formula was to show to which of the types a compound was related, and in what way it was regarded as derived from the type. It was found necessary to refer many compounds to more than one type, and this led to what was called the *theory of mixed types*. The compound methylamine may serve to illustrate this. It may be regarded as derived from ammonia, in which case it must be represented by the formula  $\begin{matrix} \text{H} \\ | \\ \text{H} \end{matrix} \text{N}$ , or it may with equal right be regarded

as derived from marsh gas, and it must then be represented by the formula  $\begin{matrix} \text{NH}_2 \\ | \\ \text{H} \end{matrix} \text{C}$ . Both these

views may, however, be harmonised, and the compound represented as belonging to both

types thus  $\begin{matrix} \text{H} \\ | \\ \text{N} \end{matrix} \begin{matrix} \text{H} \\ | \\ \text{H} \end{matrix} \text{C}$ .

It is thus seen that chemists for more than a century have attempted by means of formulæ to express their views in regard to the constitution of chemical compounds in terms of prevailing hypotheses. But the formulæ thus framed were in most cases more than mere expressions of theory. They attempted to express certain facts that were known. In the dualistic formulæ the fact was expressed that compounds are formed by the union of two parts. In the electro-chemical formulæ the fact was expressed that compounds break down into two parts under the influence of an electric current. In the formulæ representing conjugate compounds,

the fact that some of the compounds thus represented have properties highly suggestive of the fundamental substance supposed to be contained in them was recognised; and in the typical formulæ the fact that the general conduct of the compound represented is like that of the type to which it is regarded as belonging is intended to be expressed. When alcohol is represented as belonging to the water type, for example, the chemical conduct of the two substances is the justification for the view expressed. All the constitutional formulæ, then, are intended to express facts established by study of the compounds. Everything learned in regard to a compound must be in accordance with the formula, and must, if possible, find an interpretation in the formula. It would be absurd, for example, to represent a marked acid as belonging to the ammonia type, unless it could be shown that, together with its acid properties, the compound also has certain properties which suggest those of ammonia.

Let us now consider the constitutional formulæ used by most chemists of the present day. These, like all preceding constitutional formulæ, are intended to express the facts in terms of the prevailing hypotheses. The type theory gave way to the valency hypothesis which was first suggested by Frankland and afterwards elaborated by Kekulé, Couper, Kolbe and others. According to this the cause of the types is to be looked for in the atoms of which the typical compounds are made up. Atoms differ from one another in the number of other atoms which they can hold in combination at the same time. The so-called types are simply representative compounds, illustrating the forms of compounds possible in the case of monovalent, divalent, trivalent, and tetravalent, elements. Just as the atom of hydrogen is in combination with chlorine in hydrochloric acid, so each atom of hydrogen is in combination with oxygen in water, with nitrogen in ammonia, and with carbon in marsh gas. This view involves the conception of the *linkage of atoms*. Instead of conceiving each molecule of water, of ammonia, and of marsh gas, as made up of a certain number of atoms all in direct combination, we now conceive that in these molecules there are direct connexions between some of the atoms and not between others. While in the molecules named the hydrogen is in direct combination with oxygen, with nitrogen, and with carbon, it is not believed to be in direct combination with hydrogen. These views are expressed by the following formulæ:—

Each of the formulæ for water expresses exactly the same view, and so do the different formulæ for ammonia and for marsh gas. The facts which lead to the acceptance of the valency hypothesis have been considered pretty fully in the article *EQUIVALENCY* (q. v.) and they need not

be repeated here. Suffice it to say that the evidence in favour of the view that there are definite lines of connexion between the different parts of molecules is extremely strong, and that without this view it appears to be impossible to explain the many cases of isomerism which present themselves in the field of organic chemistry. In our constitutional formulæ at present we endeavour to state what lines of connexion exist in the molecules. These formulæ are based upon the molecular and atomic theory, the hypothesis of the linkage of atoms, and to some extent upon the valency hypothesis.

The difference between a *typical formula* and a *linkage-formula* is very slight in simple compounds, and when the linkage-formula is written without the use of lines or points to indicate the connexions between the atoms, it is identical in appearance with the typical formula. It is nevertheless intended to express something which the typical formula did not express. We may write methyl alcohol:—

Each formula is intended to express exactly the same thing, and that is, that of the four hydrogen atoms contained in the molecule of methyl alcohol, three are in direct combination with carbon alone, and one with oxygen; while the oxygen is in direct combination with carbon as well as with hydrogen. The formulæ also express the relation between water and methyl alcohol, but that fact is not regarded as the principal one, as it was when the theory of types was the controlling idea. While it is not difficult to see how by means of such formulæ it is possible to express the constitution of compounds, it is not so easy to see how, when more than one formula is possible for the same compound, the selection is made. It is thought by some that, in order to express the constitution of a compound, it is only necessary to know the valencies of the atoms which form the molecule of the compound, and to arrange these atoms in such a way as to satisfy all the hypothetical affinities or bonds. Thus the constitution of sulphuric acid is written  $\text{S} \begin{array}{c} \text{O}-\text{H} \\ | \\ \text{O}-\text{O}-\text{H} \end{array}$

by some, because sulphur and oxygen are divalent and hydrogen is monovalent. In this case to be sure there are two other ways in which the constitutional formula may be written on the above assumptions. They are  $\text{H}-\text{O}-\text{S}-\text{O}-\text{O}-\text{H}$  and  $\text{H}-\text{S}-\text{O}-\text{O}-\text{O}-\text{H}$ . Such formulæ, however, are conventional methods of expressing certain matters which call for evidence. They are simply the results of the application of the hypothesis of valency and express something in regard to which we know nothing until the subject has been investigated. Who, for example, can tell without investigation whether in sulphuric acid both hydrogen atoms are in combination with oxygen, or whether one is in combination with oxygen and the other with sulphur? One view is just as probable *a priori* as the other, and there is nothing in the hypothesis which will enable us to decide between them. And so in most other cases. The hypothesis of the linkage of atoms affords us a ready method of expressing facts which are known to us, but it does not sup-

nish us with the facts. What kinds of facts then can be expressed by means of the hypothesis, and how can we become acquainted with these facts?

Answers to these questions will best be given by means of examples. There are two compounds known which by the usual methods can easily be shown to have the molecular formula  $C_2H_2N$ . Without further information, any attempt to express views in regard to the structure of these substances would be mere speculation. By studying the chemical conduct of both we soon recognise marked differences between them. One of them shows a tendency to decompose in such a way that the nitrogen is given off in the form of ammonia, while the two carbon atoms remain. Thus, under proper conditions this decomposition takes place:

The other compound breaks down in an entirely different way, the nitrogen remaining in combination with one of the carbon atoms, and the other carbon atom being given off thus:

These facts suggest that the carbon and nitrogen in these two compounds are held together in different ways. In the first it appears probable that the connexion is as represented in the formula  $C-C-N$ ; while in the second it appears that the connexion is this,  $C-N-C$ . As regards the way in which the hydrogen atoms are held in combination, it can be shown that the compounds formed by decomposition of the two bodies under consideration contain the methyl group  $CH_3$ , which, from its formation from marsh gas, is easily shown to have the constitution repre-

sented by the formula  $\begin{array}{c} H \\ | \\ H-C-H; \end{array}$  or, to be more strictly accurate, the formation from marsh gas shows that if marsh gas has the formula

As the valency of the carbon atom is never greater than four, so far as is known, it appears that the first of the two compounds has the constitution  $H_2C-O-N$ , and the other the constitution  $H_2C-N-C$ . These formulæ are in accordance with the decompositions above mentioned, and they suggest the conduct of the substances. Again, the methods of formation of the substances confirm the conclusions already drawn in regard to their constitution. Both are formed when a salt of hydrocyanic acid is treated with a mono-halogen derivative of marsh gas such as methyl iodide  $CH_3I$ . According to the prevailing notions, for which there is abundant evidence, methyl iodide is marsh gas in which one atom of hydrogen has been replaced by one atom of iodine. Its constitution is therefore represented thus:

When this is treated with silver cyanide the silver and iodine unite and the residue of marsh gas, i.e. methyl,  $CH_3$ , unites with the cyanogen. Thus a compound is formed

which is represented by the formula  $H_3C(OH)$ . And, just as the silver salt is called silver cyanide, so this compound would naturally be called methyl cyanide. But, as already stated, there are two compounds formed. One is called *methyl cyanide*, and the other *methyl isocyanide*. While the method of formation plainly indicates the presence of methyl in both compounds, it does not give any clue to the way in which the carbon and nitrogen of the cyanogen are united with the methyl. According to all we know concerning carbon and nitrogen, either may act as a linking element, so that the two possibilities suggest themselves which are represented by these formulæ,  $H_3C-O-N$  and  $H_3C-N-C$ . We do not know whether silver cyanide has the structure  $Ag-O-N$  or  $Ag-N-C$ ; as both the methyl compounds mentioned are formed by treating silver cyanide with methyl iodide, it seems not improbable that the salt contains both varieties. However this may be, it is clear that the method of formation of the methyl compounds does not afford us any clue to the structure of the cyanogen group. Our information in regard to this is obtained solely by a study of the decompositions of the compounds.

For the two formulæ under discussion we have experimental evidence, and the formulæ express the results of experiments. These results are interpreted in terms of the linkage-hypothesis. So far these formulæ are practically independent of the hypothesis of valency. The conception that the molecule of marsh gas consists of one carbon atom in combination with four hydrogen atoms is a necessary consequence of the view that the molecule is symmetrical, and this view is entirely in accordance with all facts known regarding the compound. This conception is not perhaps so much a result of the application of the hypothesis of valency, as of our knowledge of the conduct of marsh gas. On now examining the formulæ for methyl cyanide and methyl isocyanide in the light of the hypothesis of valency, we see that in that of methylcyanide,  $H_3C-O-N$ , one carbon atom is represented as tetravalent, the other as divalent, and the nitrogen as monovalent. In the formula of the isocyanide,  $H_3C-N-C$ , one carbon atom appears to be tetravalent, one monovalent, and the nitrogen divalent. But, as in most compounds carbon is tetravalent and nitrogen either trivalent or pentavalent, it is generally held that in these compounds they also act in this way, and the formulæ are written so as to indicate this. Methyl cyanide is represented thus  $H_3C-O\equiv N$ , and the isocyanide thus  $H_3C-N\equiv C$ , the nitrogen being trivalent in the former and pentavalent in the latter. It will be seen that the chief reason for writing the formulæ in this way is to account for the distribution of the hypothetical bonds or affinities. No experimental evidence has been furnished in favour of these formulæ, and, so far as our knowledge of facts is concerned, the simpler formulæ represent just as much as the more complex ones.

The two examples discussed will give a fair idea of the methods in use for determining the structure or constitution of compounds and of expressing the results by means of formulæ. The results reached by a study of the reactions of a compound are expressed by means of a

**reaction-formula.** Those reached by a study of the method of synthesis of a compound are expressed by means of a *synthesis-formula*. As it is found that in most cases the reaction-formula is identical with the synthesis-formula, the expression is called a *structural or constitutional formula*. The structure or constitution may be expressed by means of a simple *linkage-formula* in which the connexions between the atoms as determined by experiments are pointed out; or a *valency-formula* in which an attempt is made to express different kinds of connexions between atoms. The linkage-formula is based upon experiments; the valency-formula, so far as it expresses more than the linkage-formula, is almost wholly an expression of an hypothesis.

The constitutional formulæ of all the great groups of chemical compounds have been determined by experiments, and they are of great value in enabling chemists to express very concisely in intelligible language the results of experiments. As it is found that a certain kind of constitution carries with it a certain set of properties, the formula conveys to the mind at once a clear impression in regard to the general properties of the compound represented. It has been shown by experiment that in every alcohol hydrogen is linked to oxygen, and the group thus formed, which is called hydroxyl, is in turn linked to a hydrocarbon residue. Methyl alcohol, for example, is represented thus  $\text{H}_3\text{C}-\text{O}-\text{H}$ . Now, whenever we see an expression of this kind  $\text{R}-\text{O}-\text{H}$ , in which R is any hydrocarbon residue, we may expect that the substance thus represented has certain general properties which are characteristic of all alcohols. The analogy between these substances and water and the metallic bases is also clearly indicated by their formulæ. Thus we have this series:—

$\text{H}-\text{O}-\text{H}$  water,  
 $\text{K}-\text{O}-\text{H}$  potassium hydroxide,  
 $\text{Na}-\text{O}-\text{H}$  sodium hydroxide,  
 $\text{M}-\text{O}-\text{H}$  any hydroxide of a monovalent metal,  
 $\text{H}_3\text{C}-\text{O}-\text{H}$  methyl alcohol,  
 $\text{H}_2\text{C}_2-\text{O}-\text{H}$  ethyl alcohol,  
 $\text{R}-\text{O}-\text{H}$  any alcohol containing a monovalent residue of a hydrocarbon.

A very interesting piece of evidence in favour of the linking represented in these formulæ is furnished by the action of a reagent which has the power of removing oxygen and putting chlorine in its place. Such a reagent is pentachloride of phosphorus,  $\text{PCl}_5$ . When it is brought in contact with a substance containing oxygen this element is abstracted and two chlorine atoms from the pentachloride take the place of each atom of oxygen. If the oxygen serves the purpose of a linking element, as it does in the compounds above represented, the compound breaks down in such a way that the parts linked together by the oxygen appear in separate molecules. Thus, replacing the oxygen in the above compounds by chlorine, we should have this series:—

$\text{H}-\text{Cl}$   $\text{Cl}-\text{H}$   
 $\text{K}-\text{Cl}$   $\text{Cl}-\text{K}$   
 $\text{Na}-\text{Cl}$   $\text{Cl}-\text{Na}$   
 $\text{M}-\text{Cl}$   $\text{Cl}-\text{M}$   
 $\text{H}_3\text{C}-\text{Cl}$   $\text{Cl}-\text{H}_3\text{C}$   
 $\text{H}_2\text{C}_2-\text{Cl}$   $\text{Cl}-\text{H}_2\text{C}_2$   
 $\text{R}-\text{Cl}$   $\text{Cl}-\text{R}$

VOL. II.

In each case decomposition takes place, and two molecules are formed from one. The general reaction in the case of metallic hydroxides is:  $\text{M}-\text{O}-\text{H} + \text{PCl}_5 = \text{POCl}_3 + \text{MCl} + \text{HCl}$ ; and in the case of alcohols it is:

It is evident that oxygen has some power which chlorine does not possess. It can link together hydrogen and another element, while in the cases mentioned chlorine cannot. In a similar way an elaborate study of acids has shown that in most of them the hydrogen which is replaceable by metallic elements is in combination in the form of hydroxyl, but the hydroxyl instead of being in direct combination with a metal, as in the hydroxides above referred to, is generally in combination with some element which is in turn in combination with oxygen. The constitution of nitric acid, for example, has been found to be probably represented thus  $\text{O}_2\text{N}-\text{O}-\text{H}$ ; sulphuric acid thus  $\text{O}_2\text{S} \begin{smallmatrix} \text{O}-\text{H} \\ \text{O}-\text{H} \end{smallmatrix}$ ; permanganic acid thus  $\text{O}_2\text{Mn}-\text{O}-\text{H}$ ; chromic acid thus  $\text{O}_2\text{Cr} \begin{smallmatrix} \text{OH} \\ \text{OH} \end{smallmatrix}$ .

&c., &c. So too the carbonates are found to be derived from an acid which probably has the structure represented by the formula  $\text{OC} \begin{smallmatrix} \text{OH} \\ \text{OH} \end{smallmatrix}$ .

On studying the acids of carbon, or the so-called organic acids, most of them are found to contain hydroxyl in combination with carbonyl, forming together the group known as carboxyl which has the structure  $\text{OC}-\text{O}-\text{H}$ . The greater number of the monobasic carbon acids may be represented thus  $\text{OC} \begin{smallmatrix} \text{R} \\ \text{OH} \end{smallmatrix}$  or  $\text{R.CO.OH}$ . These formulæ show the relations which exist between the acids in question and carbonic acid. If in the latter we suppose a hydroxyl group replaced by a residue like methyl, ethyl, &c., the result is a carbon acid or an organic acid. Acetic acid is  $\text{OC} \begin{smallmatrix} \text{CH}_3 \\ \text{OH} \end{smallmatrix}$ ; propionic acid is  $\text{OC} \begin{smallmatrix} \text{C}_2\text{H}_5 \\ \text{OH} \end{smallmatrix}$ ; or these formulæ may also be written  $\text{CH}_3\text{CO.OH}$  and  $\text{C}_2\text{H}_5\text{CO.OH}$  respectively. These are linkage-formulæ based upon experiments. If we write them thus

we then have to deal with valency-formulæ, and they, as already remarked, convey no more information than the linkage-formulæ, unless by further experiments we become acquainted with facts which justify us in expressing the relation between the hydroxylic oxygen and carbon in a different way from that in which we express the relation between the carbonylic oxygen and carbon. In this case we are certainly justified in making the distinction. It is found that when the oxygen of the hydroxyl is replaced by chlorine, one chlorine atom takes the place of the hydrogen and oxygen of the hydroxyl, and the other passes off in combination with hydrogen as hydrochloric acid. It appears therefore that but one chlorine atom can enter in the place formerly occupied by the hydroxylic oxygen. This is represented by the single line  $\text{O}-\text{O}-\text{H}$ . On the other hand, under a change

P P

of conditions, it is found possible to replace the carbonylic oxygen by chlorine, and in this case two chlorine atoms enter into the molecule in place of the oxygen. This we may represent by two lines thus,  $C=O$ . In this case then the for-

mula  $\begin{array}{c} O \\ || \\ C-O-H \end{array}$  is more than a mere application of the valency-hypothesis, it is the expression in a particular language of a number of facts, among which are some which justify the use of the double line, if that is used simply as an expression of the facts.

It is not the purpose of this article to show how the structural formulae of all the different classes of compounds are deduced from experimentally determined facts, but rather to illustrate the general principles which are made use of, and to show in what way the formulae express the facts. The question of single and double union has just been touched upon in connexion with the relations existing between carbon and oxygen. The same question has frequently been discussed with special reference to the relations between carbon atoms. A concrete case is that of ethylene. As is well known, this hydrocarbon has the molecular formula  $C_2H_4$ . It is obtained from ethane  $C_2H_6$  by the indirect abstraction of two atoms of hydrogen, or from alcohol  $C_2H_5-O-H$  by the abstraction of the elements of water. In ethane it is assumed that the linkages occur as represented

by the formula  $\begin{array}{c} H & H \\ | & | \\ H-C & -C-H \\ | & | \\ H & H \end{array}$ ; and in alcohol as

represented by the formula,  $\begin{array}{c} H & H \\ | & | \\ H-C & -C-O-H \\ | & | \\ H & H \end{array}$ .

Now when hydrogen is abstracted from ethane, or water from alcohol, the action may plainly take place in two ways so as to form a com-

pound of the structure,  $\begin{array}{c} H & H \\ | & | \\ H-C & -C-H \\ | & | \\ & H \end{array}$ , or one of

the structure  $\begin{array}{c} H & H \\ | & | \\ C & -C \\ | & | \\ H & H \end{array}$ . But when ethylene is

treated with chlorine a compound of the formula  $C_2H_4Cl_2$  is formed, and it has been shown that in this compound each chlorine is in combination with a different atom, as represented in the

formula  $\begin{array}{c} H & H \\ | & | \\ Cl-O & -C-Cl \\ | & | \\ H & H \end{array}$ . It appears from this

that ethylene is, in all probability, made up as

represented in the formula  $\begin{array}{c} H & H \\ | & | \\ C & -C \\ | & | \\ H & H \end{array}$ . So far this

formula expresses all that we have learned, and it appears that, in ethylene, carbon is trivalent.

But ethylene has a power which ethane has not. It can take up two atoms of hydrogen, of chlorine, bromine, &c. It is unsaturated. We may

represent this fact by the formula  $\begin{array}{c} H & H \\ | & | \\ -C & -C- \\ | & | \\ H & H \end{array}$ ,

which, if interpreted in terms of the hypothesis of valency, means that two of the affinities of each carbon atom are employed in holding hydrogen in combination, one of each in holding the two carbon atoms together, and one of each is unemployed. There are several objections to this view. In the first place it implies that a part of an atom can be acting while another part is doing nothing, a state of things which it is impossible to conceive. In the next place if a compound with free affinities can exist, why should we not be able to isolate the hydrocarbon

$CH_2$ ? This compound cannot be isolated. It is

necessary to have a molecule containing at least two carbon atoms before it is possible to get a compound of the ethylene series. This makes it appear probable that the kind of unsaturation found in ethylene is dependent upon some change in the relations of the carbon atoms. The difference between the relation in ethane and in ethylene may be represented by the signs  $C-C$  and  $C=C$ . The second, or ethylene sign, suggests at once the sign used to express the carbonyl relation between carbon and oxygen. On comparing the reactions of ethylene compounds with those of carbonyl compounds, we find indeed that they have certain features in common. This is seen in their conduct under the influence of nascent hydrogen. Ethylene is converted by this reagent into the saturated compound ethane, the action being represented in this way:

$\begin{array}{c} H & H \\ | & | \\ C=C + 2H = & H-C & -C-H \\ | & | \\ H & H \end{array}$  So too acetone,

$\begin{array}{c} H & H \\ | & | \\ H-C & -C-H \\ | & | \\ H & H \end{array}$  which may be taken as a convenient example of carbonyl compounds, takes up two atoms of hydrogen and is converted into the saturated compound, isopropyl alcohol, as represented in

the equation  $\begin{array}{c} H & O & H \\ | & || & | \\ H-C & -C & -C-H + 2H = \\ | & | & | \\ H & H & H \end{array}$

$\begin{array}{c} H & H & H \\ | & | & | \\ H-C & -C & -C-H \\ | & | & | \\ H & O & H \\ | & & | \\ H & & H \end{array}$ . While then it is impos-

sible at present to say what relation the condition which we call single union bears to that which we call double union, still we cannot avoid recognising that there are at least two kinds of relations between atoms, and these two kinds may be conveniently expressed by the signs under discussion.

A similar study of acetylene,  $C_2H_2$ , and certain cyanogen derivatives, shows that, if we

recognise the distinction between single and double union, we must also recognise a third kind of relation, which by analogy we should call triple union. This condition is most distinctly represented in acetylene. It carries with it the power to take up four monovalent atoms, just as the double union condition carries with it the power to take up two monovalent atoms. Acetylene becomes ethane under the influence of nascent hydrogen as expressed thus:  $C_2H_2 + 4H = C_2H_6$ . The same power is seen in the cyanides. Thus, methyl cyanide, which, assuming the condition of triple union between the carbon and nitrogen in the cyanogen group, is expressed thus,  $CH_3-C \equiv N$ , takes up four atoms of hydrogen, and is converted into ethylamine; thus  $CH_3-C \equiv N + 4H = CH_3-CH_2-NH_2$ ; a transformation which is plainly of the same kind as that which takes place when acetylene is transformed into ethane. It should be distinctly stated that the signs used to express double union and triple union are not intended to convey the idea that the condition of single union, whatever that may be, is repeated twice or three times. They simply express relations different from that of single union, relations which we recognise by means of definite reactions. The double line certainly does not mean that the union expressed by it is twice as strong as that expressed by the single line. Indeed it is clear, from a study of compounds in which the ethylene condition exists, that the double union is less firm than the single, and the study of compounds of the acetylene order shows equally plainly that triple union is the least firm of the three.

If we should examine all the linkage formulae of complex compounds which have been determined experimentally, we should find that, in general, the linking takes place in accordance with the laws of valency. In many cases, however, the linkages are less in number than we should be led to expect from our knowledge of the valencies of the elementary atoms. In these cases, it is generally found that the compounds have the power of forming additive compounds in which each element acts with its maximum valency.

The methods for determining constitutional formulae thus far considered are purely chemical. They are based upon a careful study of the decompositions, syntheses, and transformations, of the compounds. The question will suggest itself, whether it is possible by a study of physical properties to throw any light upon structure. Several attempts have been made in the direction indicated. The methods will not be considered here at all in detail, as they will form the subject of other articles. The properties which have been most elaborately studied are; specific volume, molecular refraction, polarisation-phenomena, magnetic rotation, and thermal phenomena.

The specific volume, or molecular volume, of a substance is represented by a figure obtained by dividing the molecular weight of the substance by its specific gravity in the liquid form. It has been shown that the specific volume of an element in combination can sometimes be determined by studying a number of its compounds, the general principle made use of being this: the specific

volume of a certain compound is determined and then that of another compound differing from the first by 1 or 2 atoms of the element; the difference between the two specific volumes is regarded as the specific volume of 1 or 2 atoms of the element by which the two compounds differ. It appears from investigations thus far carried out that the specific volume of oxygen has two values according as it is in the hydroxylic or the carbonylic condition. Assuming this to be established, it is clear that, by determining the specific gravity of a compound in liquid form, and without studying its chemical reactions, we might be able to decide whether an oxygen atom contained in it is in one or the other of the two conditions mentioned.<sup>1</sup>

As regards molecular refraction, it has been shown that, in general, compounds of the same composition have the same refraction-equivalent. The refraction equivalent is represented by the expression  $P \left( \frac{n-1}{d} \right)$ , in which P is the molecular weight of the substance,  $n$  the index of refraction, and  $d$  the relative density of the substance. A more elaborate study of this subject has shown that the molecular refraction of a substance is influenced by the presence of the condition of double or triple union. The occurrence in a compound of one double linkage causes a definite increase in the molecular refraction. So, also, the presence of carbonyl, CO, causes an increase in the molecular refraction above that found when the oxygen is present in the singly linked condition, as in hydroxyl C—O—H. If these rules can be proved to be well founded we have a method which will enable us to determine whether double linkage between carbon atoms, or between carbon and oxygen, exists in compounds under examination. The method does not, however, help us at present to understand what double linkage is. It merely puts us in a position to say that, if this condition is assumed in certain compounds, it must be assumed in certain other compounds which conduct themselves in the same way.<sup>1</sup>

Recently some facts have been observed in studying the magnetic rotary power of substances which may be utilised in determining constitution. It has been shown that the addition of  $CH_3$  to a compound increases the molecular magnetic rotation by a definite quantity. So also a definite effect was shown to be produced by the introduction of methyl.\* Other results of the same general character were obtained. It is not improbable that a further study of the magnetic rotary power of chemical compounds may put us in possession of a method of considerable value. Up to the present the method as thus far developed has not come into general use. The method based upon a study of the magnetic rotary power, like those based upon a study of specific volumes and molecular refraction, does not give any information in regard to the various conditions which it is its object to detect. It merely attempts to tell us in which compounds certain conditions exist, without saying anything in regard to the nature of these

<sup>1</sup> The connections between specific volume and constitution, and between refraction and constitution, are, however, not yet anything like clearly elaborated (c. PHYSICAL METHODS).—M. M. P. M.

conditions. It is, however, quite within the range of probability that continued study of all the physical properties of compounds may lead to a satisfactory hypothesis in regard to the nature of those conditions of which we now simply recognise the existence. Thus, if it is found that, whenever double linkage occurs in a compound, certain physical properties always appear, it may be possible to frame a satisfactory hypothesis in regard to the nature of the condition which we call double linkage. If then we could express this hypothesis in our formulæ, these would be, more strictly than those now in use, *constitutional formulæ*.

The chemical methods and the physical methods thus far discussed have nothing directly to do with the relations which atoms bear to one another in space. The formulæ determined by means of them do not attempt to express space-relations, unless the fact that two atoms are represented as being in direct combination with each other implies that they are nearer each other than two atoms in the same molecule which are not in direct combination with each other. The formulæ simply represent connexions believed to exist between the different parts of molecules. We know nothing in regard to the forms of molecules, and the arrangement of atoms in space. Nevertheless, some ingenious speculations have been indulged in with reference to these space-relations. One which has received much attention, and which is certainly worthy of serious study, was suggested by observations of the effects produced by certain substances on polarised light. There are three varieties of tartaric acid; one of these turns the plane of polarisation of a ray of light to the right, a second turns it to the left, while the third is optically inactive. The third is formed by the union of the first and second, and is, therefore, probably to be regarded as differing from the active varieties in having a greater molecular weight.

The difference between the first and second tartaric acids cannot be expressed by means of our ordinary linkage-formulæ. Both are represented probably by the same formula,  $\text{CH}(\text{OH})\cdot\text{CO}\cdot\text{OH}$

which is in accordance with the chemical reactions, decompositions, and syntheses, of both. Nevertheless the two compounds differ. Several other cases of the same kind are known. This kind of isomerism, which shows itself in differences in the physical properties, and not in the chemical conduct, is called *physical isomerism*. To account for the particular kind of physical isomerism here referred to, Le Bel and Van't Hoff have made the suggestion that it may be due to a different arrangement in space of certain parts of the molecules. If the four affinities of a carbon atom be supposed to be exerted in the direction of the angles of a tetrahedron, the carbon atom being at the centre of the tetrahedron, there are two ways in which four different atoms or groups can be conceived to be combined with the carbon. Arranging these atoms or atomic groups in any way, the other possible arrangement is found by regarding the reflection of the first arrangement in a mirror.

These two kinds of arrangement in space are possible only in those compounds in which a carbon atom is in combination with four different atoms or atomic groups. Such a carbon atom is called an *asymmetric carbon atom*. Now, it is a remarkable fact that optically active compounds always contain one or more asymmetrical carbon atoms. Some attempts have been made to express by means of formulæ the space-relations suggested in the above hypothesis (v. especially Wislicenus, *K. Sächsischen Ges. der Wissenschaften*, 14, 1).

It has been pointed out by Brühl that the boiling-points, densities, and indices of refraction, of isomeric compounds vary in the same way; that for isomeric compounds the constants of that one are largest which consists of an uninterrupted chain of hydrocarbon residues, and that the constants become smaller the more the structure of the molecule is branched, and deviates from one direction. The data thus far in our possession seem also to show that the shorter the molecule of isomeric compounds, i.e. the more they approach the spherical form, the larger is the molecular volume. The words 'shorter,' 'branched,' &c., used in these statements, have primarily, of course, reference to the appearance of the formulæ in common use, and which, as already explained, are not intended to represent the arrangement of atoms in space. But, assuming that they do in a rough way represent the shapes of the molecules, it appears that there probably exists a direct connexion between the variations in the physical constants of isomeric compounds and the shapes of their molecules. Thus, the specific gravity of compounds with long molecules would necessarily be greater than that of compounds with branched or spherical molecules, for the same reason that we can get more rods in a given space than spheres of the same weight. So also with reference to the boiling-points. The rod-shaped molecules offer the most points of contact, the spherical the fewest. The cohesion between molecules of the first kind will hence be the greatest, and the conversion of a substance made up of such molecules into vapour will require more heat, or the boiling-point will be higher, than in the case of a substance made up of molecules of the branched or spherical kind. It will thus be seen that we have faint suggestions that our linkage-formulæ have some relation to the arrangement of atoms in space, though primarily they are not intended to express facts of this order. I. R.

**FORMYL.** The radicle  $\text{CHO}$ , the lower homologue of acetyl. The term was at one time applied to the radicle  $\text{CH}$  now called *methenyl*. The formyl derivatives of amines are described under the amines from which they are derived.

**FORMYL-CAMPHOR**  $\text{C}_{11}\text{H}_{18}\text{O}$  i.e.

Formed on treating camphor with formic ether:

Separated by solution in alkalis, shaking with ether, acidifying with acetic acid, shaking again with ether and evaporating (Bishop a. Claisen, *B.* 22, 538). Crystalline. Its properties are like those of the ketonic aldehydes  $R.CO.CHR'.COH$ . It is a moderately strong acid, v. sol. caustic alkalis.  $FeCl_3$  gives a dark violet solution.

Salt.— $A_2Cu$ : bright green crystalline pp.; bl. sol. water; v. sol. organic solvents.

*Anilide*  $C_{12}H_{11}O.OH:N.Ph$ : [153°]; colourless, crystallising well.

**FORMYL-TRICARBOXYLIC ACID** v. **METHANE-TRICARBOXYLIC ACID**.

**FORMYL CYANURAMIDE**. Described under **CYANIC ACID** as a derivative of cyanuramide.

**FORMYL-MELAMINE**. Described, as a derivative of cyanuramide, under **CYANIC ACID**.

**FORMYL-PHENYL-ACETIC ACID**

$HCO.CHPh.CO_2H$ . *Ethyl ether EtA'*. (145°) at 16 mm. Formed by suspending dry  $NaOEt$  in ether (3 pts.), adding a mixture of formic ether and phenyl-acetic ether, and keeping the whole for several days in a closed vessel. The product is shaken with water at 0°, acidified, and extracted with ether (Wislicenus, *B.* 20, 2930). Oil. Decomposed by boiling with aqueous  $NaOH$  into formic and phenyl-acetic acids. The alcoholic solution gives a bluish-violet colouration with  $FeCl_3$ . Phenyl-hydrazine forms  $CO < \overset{Ph.N}{\underset{CHPh}{\text{C}}} > CH$  [196°]. Formyl-phenyl-acetic ether changes spontaneously, especially at 70°, into a crystalline isomeride [70°]; this isomeride is also split up by alkalis into formic and phenyl-acetic acids.

**DI-FORMYL-PHENYLENE-DIAMINE** v. **PHENYLENE-DIAMINE**.

**FORMYL-PROPIONIC ACID**

$HCO.CHMe.CO_2H$ . (161°). Formed by the action of  $NaOEt$  on a mixture of formic and propionic ethers (Wislicenus, *B.* 20, 2930). Oil. Gives an intense reddish-violet colour with  $FeCl_3$ .

**FORMYL-UREA** v. **UREA**.

**FORMYL-XYLIDINE** v. **XYLIDINE**.

**FRAGARIANIN**. Said to occur in the root of the strawberry (*Fragaria vesca*) (Phipson, *C. N.* 38, 136). V. sl. sol. water, alcohol, and ether; potash-fusion forms from it protocatechuic acid. Boiling aqueous  $HCl$  splits it up into glucose and an amorphous red substance, fragarin.

**FRANCEINS**. A group of colouring matters obtained by the action of conc.  $H_2SO_4$  upon the haloid derivatives of benzene. From the pentachloro-benzene  $C_6HCl_5$ , the franceins have the empirical formula  $C_{12}HCl_5O_3$  (Istrati, *C. R.* 106, 277; *Bl.* [2] 48, 36). All the franceins are sol. conc.  $H_2SO_4$ , some are sol. water. Many of them dissolve in alkalis forming very soluble neutral salts. They all dissolve in alcohol forming highly-coloured dichroic solutions. They dye cotton, linen, and especially silk with shades varying from rose-colour to maroon. The depth of colour and the tinctorial power increases with the proportion of chlorine. Two franceins  $C_{12}HCl_5O_3$  are obtained by boiling pentachloro-benzene (300 g.) with Nordhausen acid (2000 c.c.) for 8 hours a day during 15 days;  $HCl$  and  $SO_2$  are given off. At the end of 15 days the acid is decanted, a fresh quantity added, and the heat-

ing continued for another fortnight. During this process the franceins gradually separate as a maroon-coloured substance. After washing with water, the francein formed in greater quantity is dissolved out in aqueous  $KOH$ , reppd. by  $HCl$ , and, when dried at 60°, exhibits a metallic green lustre. It dissolves in alcohol and in glycerine but not in water. Its alcoholic solution is red by transmitted, but yellowish-green by reflected, light, and dyes silk a rose-colour. The  $K$  salt is deep-brown with metallic lustre, and is v. sol. water forming a deep-red non-dichroic solution which gives pps. with salts of  $Ba$ ,  $Fe$ ,  $Sn$ ,  $Hg$ ,  $Al$ ,  $Mg$ ,  $Cd$ ,  $Ni$ , &c. The second francein, formed at the same time in much smaller quantity from penta-chloro-benzene, is sol. warm water but almost insol.  $KOH$  and is less sol. alcohol than its isomeride. It dyes silk a peach colour. When tetra-chloro-benzene (200 c.c.) is boiled with conc.  $H_2SO_4$  (1,200 c.c.) for 105 hours it is completely dissolved with evolution of water,  $HCl$ , and  $SO_2$ . No sulphonic acid is formed, but on treatment with water a reddish-brown solid is got. This solid dissolves easily in  $KOH$  and in alcohol; its alcoholic solution is pale brown by transmitted, and dull green, by reflected, light. According to Georgesco a. Mincon (*Bl.* [2] 50, 623), this francein is  $C_{12}H_2Cl_4O_3$ , and forms an insoluble silver salt  $C_{12}Ag_2Cl_4O_3$ .

**FRANGULIN**  $C_{15}H_{10}O_5$ ? (Schwabe, *Ar. Ph.* [3] 26, 560). [230°]. A yellow crystallisable colouring matter contained in the bark of the berry-bearing alder (*Rhamnus Frangula*). It is accompanied by an amorphous yellow resin, and occurs most abundantly in the older branches, the younger branches containing more of the resin (Casselmann, *A.* 104, 77).

*Preparation*.—The bark is digested for three days with alcohol (90 p.c.) at 25° to 30°; the resulting tincture is concentrated by evaporation and freed from tannin &c. by pps. with lead acetate; lead subacetate is added to the filtrate, and the pp. is suspended in alcohol and decomposed by  $H_2S$ . The boiling liquid is filtered, and on cooling deposits crystals of frangulin (Faust, *A.* 165, 229; *Z.* [2] 5, 17; Liebermann a. Waldstein, *B.* 9, 1775).

*Properties*.—Lemon-yellow crystalline mass with dull silky lustre. Insol. water; soluble in 160 pts. of warm dilute (80 p.c.) alcohol, nearly insol. cold alcohol, sl. sol. ether, sol. hot fixed oils, benzene, and oil of turpentine. May be partially sublimed as minute golden needles ( $O$ ). In aqueous alkalis it forms a deep cherry-red solution from which it is reppd. by acids but not by metallic salts. Conc.  $H_2SO_4$  forms a dark-red solution which becomes brown on heating; it is reppd. by water. Boiling conc.  $HNO_3$  dissolves it without decomposition ( $O$ ). Fuming  $HNO_3$  forms oxalic acid and so-called 'nitro-frangulic acid'  $C_{15}H_8N_2O_{11}$ ? (Hesse, *A.* 117, 349) which crystallises in orange-red needles (from alcohol). Frangulin is split up by boiling dilute  $HCl$  into glucose and epodin, a tri-oxy-methyl-anthraquinone (Schwabe).

**FRAXIN**  $C_{15}H_{10}O_5$  14q. *Pavin*. A substance occurring in the bark of the common ash (*Fraxinus excelsior*), and also, together with esculin, in the bark of the horse-chestnut (*Aesculus Hippocastanum*), and in various species

of *Pavia* (Salm-Horstmar, *P.* 97, 327, 637; 100, 607; Rochleder, *P.* 107, 331; *J. pr.* 90, 433; Stokes, *C. J.* 9, 17; Keller, *Rep. Pharm.* 44, 438; Rochleder a. Schwarz, *A.* 87, 186; Stenhouse, *P. M.* [4] 7, 501).

**Preparation.**—1. A decoction of ash-bark (taken at the flowering-time) is ppd. by lead acetate; the filtrate is ppd. by lead subacetate, and the pp. suspended in water and decomposed by  $H_2S$  (Salm-Horstmar).—2. The aqueous decoction of horse-chestnut bark is mixed when cold with such a quantity of  $FeCl_3$  that on adding ammonia the pp. immediately separates; one-fourth of the ammoniacal filtrate is ppd. by lead acetate, the pp. is redissolved in  $H_2OAc$ , the rest of the filtrate is then acidified by acetic acid, the two portions mixed together, and, after again adding ammonia, the resulting pp. dissolved in acetic acid, freed from lead by  $H_2S$ , and left to crystallise.

**Properties.**—Tufts of colourless needles; it has a slightly bitter taste. Sl. sol. cold, v. sol. hot, water; sl. sol. cold, m. sol. hot alcohol; insol. ether (Salm-Horstmar). Stokes (*C. J.* 12, 17) found it more soluble in ether than *æsculin*. It gives off its water of crystallisation at  $110^\circ$  to  $150^\circ$ , and melts at a higher temperature ( $320^\circ$  according to Salm-Horstmar). The concentrated aqueous solution is yellow, and has an acid reaction; when largely diluted it exhibits strong bluish-green fluorescence; this fluorescence is increased by the presence of a trace of alkali, but is destroyed by acids. The alcoholic solution is likewise fluorescent.  $FeCl_3$  colours the aqueous solution green, and then yields a lemon-yellow pp. Lead acetate also gives a yellow pp. in its ammoniacal solution. Boiling dilute  $H_2SO_4$  splits fraxin up into glucose and fraxetin.

**Fraxetin**  $C_{12}H_{10}O_5$ . *S.* (cold) .1; (hot) .33. Formed as above, and also by the action of  $HCl$  on a lemon-yellow crystalline compound  $C_{22}H_{20}O_{13}$ , also occurring in horse-chestnut bark (Rochleder, *C. C.* 1864, 416). Needles (from the dilute  $H_2SO_4$  in which it is formed), or tables (from alcohol). Has a slightly astringent taste. V. sl. sol. water, sl. sol. alcohol and ether. Melts at the melting-point of tin, without turning brown. Conc.  $H_2SO_4$  forms a bright-yellow solution, whence after dilution and addition of  $NH_3$  it separates in crystals.  $HClAq$  dissolves it. Conc.  $HNO_3$  is coloured by it, dark-violet, changing to red and yellow. The aqueous solution is coloured yellow by  $NH_3$ .  $FeCl_3$  colours its aqueous solution greenish-blue. Acid ammonium sulphite dissolves fraxetin, and on adding  $NH_3$  the liquid becomes yellow, but does not turn red or blue on shaking with air (difference from *æsculetin*).

**FUCUS ALDEHYDE**  $C_8H_8O_2$ . *Fucusol. (R).* *Pyromucic aldehyde.* (1727). *S.G.* 1.150. *S.* 7 at  $13^\circ$ . A volatile oil; isomeric or possibly identical with furfural, obtained by distilling sea-weeds (*Fucus nodosus*, *F. vesiculosus*, *F. serratus*, &c.) with dilute sulphuric acid (Stenhouse, *P. M.* [3] 18, 122; 37, 226; *A.* 35, 301; 74, 278). It is washed free from accompanying acetone, distilled with steam, and dried over  $CaCl_2$ . Colourless oil; turns brown on keeping exposed to air.  $H_2SO_4$  colours it yellowish-brown;  $HClAq$  turns it green; when impure the colour in both cases is purple-red.  $KOHAlq$

colours it yellow, the colour afterwards changing to dark-red. Fucusol turns the skin deep-yellow, the spots being turned rose-red by aniline (as with furfural). When boiled with water and moist  $Ag_2O$  the silver salt of (8)-pyromucic acid is formed  $C_8H_7AgO_4$ ; (8)-pyromucic acid prepared from this salt crystallises in small rhomboidal plates [ $130^\circ$ ], whereas ordinary pyromucic acid forms flat needles [ $133^\circ$ ] (Stenhouse, *Pr.* 20, 80). Ammonium sulphide converts fucusol into thiofucusol  $C_8H_7SO_4$ , which resembles its isomeride thiofurfural. Moss (*Sphagnum*) and various species of lichen (*Cetraria islandica*, *Usnea*, and *Ramalina*) when distilled with dilute  $H_2SO_4$  yield an oil apparently identical with fucusol.

**Fucosamide**  $C_{13}H_{17}N_3O_4$ . *S.* .04 at  $8^\circ$ . This isomeride of furfuramide is obtained by the action of ammonia on fucusol. It crystallises from hot alcohol in groups of long needles. Its reactions are similar to those of furfuramide.

**Fucusine**  $C_{13}H_{17}N_3O_4$ . When fucosamide is boiled for twenty minutes with moderately concentrated aqueous  $KOH$  it melts, and is converted into an oil which solidifies on cooling to a yellowish resin. From this resin  $HNO_3$  extracts the base, and, on cooling, the nitrate crystallises out. If a slight excess of  $NH_3$  be added to an aqueous solution of the nitrate fucusine slowly separates in stellate groups of small laminae.

**Salts.**— $B^+HNO_3$ : stellate groups of long prisms (from water), or large trimetric prisms (from alcohol). Decomposes at  $100^\circ$ .— $B^+H_2PtCl_6$ : four-sided prisms (the corresponding salt of furfurine forms needles).— $B^+H_2C_2O_4$ : small silky needles; m. sol. cold water.

**FULMINATES.** Described under CYANTO ACID.

**FULMINURIC ACID.** Described under CYANTO ACID.

**FUMARAMIC ACID** *v.* *Amide* of FUMARIO ACID.

**FUMARANILIC ACID** *v.* *Anilide* of FUMARIO ACID.

**FUMARIC ACID**  $C_4H_4O_4$ , *i.e.*  $CO_2H.CH:CH.CO_2H$ . *Allo-maleic acid.* Mol. w. 116. *S.* .67 at  $16.6^\circ$  (Carius, *A.* 142, 153); (cold 70 p.c. alcohol) .48. *H.C.* 318,176 (Lougumine, *C. R.* 106, 1290). Heat of solution —5901 (Gal a. Werner, *Bl.* [2] 47, 159). Heat of neutralisation (by  $NaOH$ ) 26599 (G. a. W.).

**Occurrence.**—In various plants and fungi: fumitory (*Fumaria officinalis*), *Corydalis bulbosa*, *Glaucium flavum*, Iceland moss (*Lichen islandicus*), *Boletus pseudo-ignarius*, and *Agaricus piperatus* (Winkler, *Rep. Pharm.* 39, 48, 368; 48, 39, 363; *A.* 4, 230; Wieke, *A.* 87, 225; Probst, *A.* 31, 248; Pfaff, *Schw. J.* 47, 476; Dessaignes, *J. Ph.* [3] 82, 48; *A.* 89, 120; Bolley, *A.* 86, 44; Schödlér, *A.* 17, 148; Trommsdorff, *N. Tr.* 25, 24153).

**Formation.**—1. Together with maleic acid by the dehydration of maleic acid by heat (Lassaigne [1819], *A. Ch.* [2] 11, 98; Pelouze, *A. Ch.* [2] 56, 429; *A.* 11, 265).—2. From maleic acid by heating with aqueous  $HI$ ,  $HBr$ , or  $HCl$  (Dessaignes, *J.* 1856, 463; Kekulé, *A.* 180, 21; *Suppl.* 2, 85).—3. By treating calcium malate with  $PCl_5$ , and decomposing the resulting chloride with water (Perkin a. Dupps, *A.* 113, 24).—4. By fusing sulpho-succinic acid with potash

(Messel, *A.* 157, 20).—5. By heating bromo-succinic acid.—6. By the action of aqueous KI and copper upon di-bromo-succinic acid and its isomeride (Swarts, *Z.* 1868, 259). Also from di-bromo-succinic acid and thio-urea (Nencki a. Sieber, *J. pr.* [2] 25, 72).—7. From di-bromo-succinic ether by treatment with finely divided silver and saponification of the product (Gorodetzky a. Hell, *B.* 21, 1802).—8. By heating succinimide with bromine at 180° in sealed tubes (Kisielinski, *Sitz. W.* 74, 561).—9. By boiling silver malonate with di-chloro-acetic acid and a little water (Komnenos, *A.* 218, 169).—10. By treating asparagin or aspartic acid with Mel and KOH (Körner a. Menozzi, *G.* 13, 352).—11. From (5)-bromo-pyromucic acid, bromine, and water (Hill a. Sanger, *A.* 232, 53; cf. Limpincht, *A.* 165, 289).—12. By treating  $\beta$ -di-chloro-propionic ether with KCy, and decomposing the product by KOH (Werigo a. Tanatar, *A.* 174, 368).—13. By boiling chloro-ethane-tricarboxylic ether (prepared by the action of Cl on ethane tricarboxylic ether  $(\text{CO}_2\text{H})\text{CH}_2\text{CH}(\text{CO}_2\text{H})$ , with HCl (Bischoff, *B.* 13, 2162).—14. According to Mühlhäuser (*A.* 101, 171) fumaric acid is among the products of the action of aqua regia on proteid compounds.—15. By heating ethylene tetra-carboxylic acid (Conrad a. Guthzeit, *B.* 13, 2632).

**Preparation.**—Malic acid is heated at 150°, and finally to 180°, in a current of air as long as water and maleic acid distill out. The residue is washed with a little cold water and dried at 100°. 250 g. malic acid treated in this way gives 160 g. fumaric acid (Purdie, *C. J.* 39, 346; cf. Baeyer, *B.* 18, 676).

**Properties.**—Small prisms, needles, or plates. Sublimes at 200°, and when strongly heated it gives some maleic anhydride. It burns with a pale flame. The initial rate of etherification of fumaric acid (32.7) is less than that of maleic acid (51.5), but ultimately the same proportion of each (72.6 p.c.) is etherified by isobutyl alcohol (Menschutkin, *B.* 14, 2630).

**Reactions.**—1. Reduced to succinic acid by adding sodium-amalgam to its aqueous solution, or by heating with  $\text{HI}$  aq.—2. Heated with  $\text{HBr}$  aq at 120° it is slowly transformed into bromo-succinic acid.—3. It combines very slowly with bromine in the cold, but when heated with bromine and water at 100° di-bromo-succinic acid is formed in a few minutes (Kekulé, *A. Suppl.* 1, 129; Petrie, *A.* 195, 56).—4. Zinc dissolves in aqueous fumaric acid, forming zinc-fumarate, and giving off hydrogen (Kekulé, *A. Suppl.* 2, 198). When zinc and fumaric acid are placed together in cold water hydrogen is not evolved, but zinc fumarate is formed, while succinic acid remains in solution (Von Victor, *Z.* [2] 4, 454). When fumaric acid is gently heated with zinc and excess of potash-solution it is reduced to succinic acid ( $\text{K}$ ).—5. Fumaric acid is not oxidised by boiling  $\text{HNO}_3$ , by water and  $\text{PbO}_2$ , or by  $\text{K}_2\text{Cr}_2\text{O}_7$ . Aqueous  $\text{KMnO}_4$  oxidises it to racemic acid.—6. *Electrolysis* of an aqueous solution of sodium fumarate gives acetylene,  $\text{CO}_2$ , and hydrogen (Kekulé, *A.* 181, 85).—7. *Chlorine* forms di-chloro-succinic and tri-chloro-acetic acids (Pétrieff, *Bl.* [2] 41, 809).—8. *Hypochlorous acid* forms a compound  $(\text{CO}_2\text{H})\text{CHCl}(\text{OH})(\text{CO}_2\text{H})$ , which yields inactive malic acid when reduced by

sodium-amalgam ( $\text{P}$ ).—9. Aqueous  $\text{NaOH}$  at 100° slowly forms inactive malic acid.—10. *Water* in large quantity at 150° also forms inactive malic acid (Jungfleisch, *B.* 12, 370; Pictet, *B.* 14, 2648).—11. Boiling aqueous  $\text{K}_2\text{SO}_4$  forms potassium sulpho-succinate.—12. *Acetyl chloride*, in presence of  $\text{HOAc}$  at 100°, dissolves fumaric acid in twenty-four hours, the product being maleic anhydride (Perkin, *C. J.* 39, 560; 41, 268), while, according to Anschütz (*B.* 10, 1881; 14, 2792), pure  $\text{AcCl}$  has no action on fumaric acid. By heating fumaric acid with pure  $\text{AcCl}$  at 140° Perkin (*B.* 15, 1073) obtained maleic anhydride and a little chloro-succinic anhydride; the latter being probably an intermediate body in the formation of maleic anhydride (Anschütz a. Bennert, *B.* 15, 640).—13. *Fumaric chloride* alone, or dissolved in benzene, reacts with silver fumarate, forming maleic anhydride. Fumaric chloride, dissolved in light petroleum, is converted by  $\text{Na}_2\text{CO}_3$  into maleic anhydride. It is evident, therefore, that there is but one anhydride for the two isomeric acids, fumaric and maleic.—14. A dilute aqueous solution containing fumaric acid and aniline in proportion to form the acid aniline salt gives, on heating, no anilide (difference from maleic acid) (Michael, *Am.* 9, 180).—15. Excess of alcoholic ammonia at 150° for twenty hours forms inactive aspartic acid (Engel, *C. R.* 104, 1805).

**Salts.**—None of the fumarates dissolve in alcohol. Solutions of the alkaline fumarates are not ppd. by salts of Zn, Al, or Cr.— $(\text{NH}_4)_2\text{A}$ : v. sol. water, converted into the acid salt by evaporation.— $(\text{NH}_4)\text{HA}$ : monoclinic prisms (Delffs, *P.* 80, 435; Pasteur, *A. Ch.* [3] 81, 91).— $\text{K}_2\text{A}$  2aq: large transparent trimetric tables and four-sided prisms or radiating groups of laminae. V. sol. water; from a concentrated solution acetic acid throws down the acid salt.— $\text{KHA}$ : tufts of needles, sl. sol. cold, v. sol. hot, water (Carius, *B.* 4, 929; *A.* 142, 153).— $\text{K}_2\text{H}_2\text{A}$ : acicular prisms. S. 2.66 at 19.5°.— $\text{Na}_2\text{A}$  aq: crystalline powder; ppd. by adding alcohol to its aqueous solution.— $\text{Na}_2\text{A}$  3aq: needles and prisms. V. sol. cold water.— $\text{Ag}_2\text{A}$ : fine white powder, thrown down by adding  $\text{AgNO}_3$  to a solution of (even 1 pt. in 200,000 of) fumaric acid. Deflagrates when heated. Insol. water, sol.  $\text{HNO}_3$  aq and  $\text{NH}_4\text{A}$  aq.— $\text{Ag}_2\text{A}$  aq (Carius): sol. hot water.— $\text{BaA}$ : Obtained by dissolving fumaric acid in a hot solution of barium acetate (fumaric acid does not ppt. baryta water). Crystalline grains.— $\text{BaA}$  1½aq. From  $\text{K}_2\text{A}$  and  $\text{BaCl}_2$ . Small efflorescent prisms. S. (of  $\text{BaA}$ ) 966 at 17°.— $\text{BaA}$  8aq: small white prisms. Converted by boiling with water into insoluble grains of  $\text{BaA}$  (Anschütz, *B.* 12, 2282).— $\text{SrA}$  3aq: from fumaric acid and  $\text{SrO}_2\text{Ac}$ . Crystalline powder, sl. sol. water.— $\text{CaA}$  8aq. Occurs in fumitory. From  $\text{K}_2\text{A}$  and  $\text{CaO}_2\text{Ac}$ . Shining scales, sl. sol. water, permanent in the air. Gives calcium succinate when exposed in contact with fermenting cheese to the air.— $\text{CaA}$  1½aq (dried over  $\text{H}_2\text{SO}_4$ ).— $\text{MgA}$  4aq: white powder.— $\text{Hg}_2\text{A}$ : white crystalline pp. (Rieckher, *A.* 49, 81).— $\text{PbA}$  2aq. Formed by heating lead malate to 200° (R.). Also from  $\text{K}_2\text{A}$  and aqueous  $\text{PbO}_2\text{Ac}$ , acidulated with  $\text{HOAc}$ . Tufts of shining needles. Nearly insol. cold, sol. hot, water; insol.  $\text{HOAc}$ ; sol.  $\text{HNO}_3$  aq.— $\text{PbA}$  3aq (Pelouze).— $\text{A}$  ( $\text{PbOH}$ ),

(at 100°). Ppd. by adding ammonium fumarate to boiling aqueous lead subacetate (Otto, *A.* 127, 178).— $(\text{PbA}')_2\text{PbO}$  3aq. (R.).— $\text{PbA}''(\text{PbO})$  3aq. (R.).— $\text{CuA}''$  3aq. From  $\text{CuO}_2\text{Ac}$  and fumaric acid. Bluish-green crystalline powder; sl. sol. water, v. sol.  $\text{HNO}_3$ .— $\text{A}''\text{FeOH}$ . Pale brownish-red pp. formed by adding  $\text{FeCl}_3$  to ammonium fumarate: insol. excess of ammonium fumarate (difference from succinate); insol.  $\text{NH}_4\text{Ac}$ , sol. mineral acids.— $\text{NiA}''$  4aq: pale-green powder, sol. water and ammonia solution.— $\text{CoA}''$  3aq. Obtained by adding alcohol to a concentrated solution of fumaric acid in aqueous  $\text{CoO}_2\text{Ac}$ . Rose-coloured powder, v. sol. water and  $\text{NH}_4\text{Ac}$ .— $\text{MnA}''$  3aq. From fumaric acid and  $\text{MnO}_2\text{Ac}$ . White powder, sl. sol. water.— $\text{ZnA}''$  3aq: large prisms (from hot solutions), v. sol. water.— $\text{ZnA}''$  4aq: efflorescent crystals (by spontaneous evaporation).

**Methyl ether**  $\text{MeA}'$ . [103°]. (192° i. v.). **Formation**.—1. By the action of  $\text{ZnCl}_2$  or  $\text{H}_2\text{SO}_4$  on fumaric acid in  $\text{MeOH}$  (Anschütz, *B.* 12, 2282; Ossipoff, *J. R.* 11, 288).—2. By the action of iodine on methyl maleate.—3. From methyl bromo-succinate by treatment with  $\text{KCy}$  in ether, or by subliming the same ether with  $\text{NaOAc}$  and  $\text{CaCO}_3$  (Volhard, *A.* 242, 160).—4. By the action of  $\text{NaOMe}$  on a solution of fumaric ether in  $\text{MeOH}$  (Purdie, *C. J.* 51, 627).—5. By boiling methyl diazo-succinate with water or  $\text{MeOH}$  (Curtius a. Koch, *B.* 18, 1296).

**Properties**.—Triclinic prisms (Bodewig, *Z. K.* 5, 563). Sl. sol. water, alcohol, ether, and  $\text{CS}_2$ , in the cold. Combines with bromine forming methyl di-bromo-succinate [62°]. With an equivalent quantity of diazo-acetic methyl ether

it forms  $\text{CO}_2\text{Me.CH.N} \begin{matrix} \text{CH} \\ \text{CO}_2\text{Me} \end{matrix}$ , an oil, whence the corresponding acid [220°] may be obtained (Buchner, *B.* 21, 2637).

**Mono-ethyl ether**  $\text{EtHA}'$ . Formed by heating fumaric acid (2 pts.) with alcohol (3 pts.) at 120° (Laubenheimer, *A.* 164, 297). Plates, sl. sol. water, v. e. sol. alcohol and ether.— $\text{AgEtA}'$ . S. 3 at 12°. Crystalline pp.

**Di-ethyl ether**  $\text{Et}_2\text{A}''$ . (215° uncor.) (P.); (218° i. v.) (A.). S.G.  $\text{D}_{20}^{20}$  1.052 (A.);  $\text{D}_{20}^{20}$  1.106 (H.). V.D. 85.6 (calc. 86). M.M. 10.119 (Perkin, *C. J. Proc.* 3, 98).

**Formation**.—1. By treating an alcoholic solution of fumaric or malic acid with  $\text{HCl}$  (Hagen, *A.* 58, 274). Some chloro-succinic ether is formed at the same time.—2. By boiling fumaric acid (149 g.) with alcohol (450 g.) and  $\text{H}_2\text{SO}_4$  (15 g.), ppg. by water, drying over  $\text{CaCl}_2$ , and distilling. The yield is good (123 g.) (Purdie, *C. J.* 39, 346).—3. From malic ether and  $\text{PCl}_5$  (Henry, *A.* 156, 177).—4. From  $\text{EtI}$  and silver fumarate (Anschütz, *B.* 11, 1644; 12, 2282).—5. By the action of finely divided silver on di-bromo-succinic ether (Gorodetzky a. Hell, *B.* 21, 1802).

**Reactions**.—1. Combines with bromine forming di-bromo-succinic ether [58°] (Ossipoff).—2. Combines with  $\text{NaOEt}$  (in alcoholic solution) forming  $\text{CO}_2\text{Et.CH.Na.CH}(\text{OEt}).\text{CO}_2\text{Et}$ . If the product is boiled with aqueous  $\text{NaOH}$ , neutralised with acetic acid and treated with  $\text{Pb}(\text{OAc})_2$ , lead fumarate is ppd. The filtrate is acidulated with  $\text{HNO}_3$ , neutralised with  $\text{NH}_3$ , and treated

with  $\text{Pb}(\text{NO}_3)_2$ , when a lead salt is ppd., whence  $\text{H}_2\text{S}$  liberates a crystalline acid  $\text{C}_4\text{H}_4\text{O}_6$  or  $\text{CO}_2\text{H.CH}_2\text{CH}(\text{OEt}).\text{CO}_2\text{H}$  [86°] (v. *Malic acid*) (Purdie, *C. J.* 39, 347). Sodium fumarate differs from ethyl fumarate in not combining with  $\text{NaOEt}$ .—3.  $\text{NaOMe}$  (in methyl alcoholic solution) reacts in a similar way forming first methyl fumarate and then  $\text{CO}_2\text{Me.CH}_2\text{CH}(\text{OMe}).\text{CO}_2\text{Me}$  or its sodium derivative (Purdie, *C. J.* 47, 855).—4. By heating with alcoholic  $\text{NH}_3$  in sealed tubes there is formed aspartic ether (152° at 25 mm.) together with a compound  $\text{C}_4\text{H}_4\text{N}_2\text{O}_6$  (c. 250°), possibly an imide of aspartic acid (Körner a. Menozzi, *G.* 17, 226).

**Iso-butyl ether**  $(\text{PrCH}_2)_2\text{A}''$ . (170°) at 160 mm. From silver fumarate and isobutyl iodide (Purdie, *C. J.* 39, 353). Not obtained quite pure. Combines with sodic isobutylate in presence of isobutyl alcohol forming a product whence, on saponification, the isobutyl derivative of malic acid (q. v.) is got.

**Phenyl ether**  $(\text{C}_6\text{H}_5)_2\text{A}''$ . [162°]. From fumaryl chloride and phenol. White needles, sl. sol. alcohol. On heating it evolves  $\text{CO}_2$ , yielding phenyl cinnamate and finally stilbene  $\text{C}_6\text{H}_5\text{C}(\text{H})=\text{C}(\text{H})\text{C}_6\text{H}_5$  (Anschütz a. Wirtz, *B.* 18, 1948; *C. J.* 47, 898).

**p-Tolylether**  $(\text{C}_6\text{H}_4)_2\text{A}''$ . [162°]; v. sl. sol. alcohol. On heating it gives s-di-tolyl-ethylene  $\text{C}_6\text{H}_4\text{C}(\text{H})=\text{C}(\text{H})\text{C}_6\text{H}_4$  [179°], and a substance crystallising in scales [79°] (A. a. W.).

**Chloride**  $\text{C}_2\text{H}_2(\text{COCl})_2$  or  $\text{C}_2\text{H}_2\langle\text{COCl}\rangle_2\text{O}$ .

**Maleyl chloride**. (160°). From malic acid and  $\text{PCl}_5$  (Perkin a. Duppa, *A.* 112, 26). Formed also by the action of  $\text{PCl}_5$  on fumaric acid or maleic anhydride (Kekulé, *A. Suppl.* 2, 86; Perkin, *B.* 14, 2548). Bromine at 150° combines with it, forming di-bromo-succinyl chloride.

**Mono-amide**  $\text{CO}_2\text{H.CH}(\text{CONH}_2)\text{CONH}_2$ . **Fumaric acid. Anhydro-aspartic acid**. [217°]. Prepared by the action of methyl iodide and caustic potash on asparagine  $\text{C}_4\text{H}_7\text{N}_3\text{O}_6 + 4\text{MeI} = \text{C}_4\text{H}_5\text{N}_3\text{O}_6 + 4\text{MeI} + 3\text{HI}$  (Griess, *B.* 12, 2117; Michael a. Wing, *Am. J.* 6, 420). Leaflets, sol. hot water and hot alcohol, almost insol. ether. Decomposed by alkalis or acids into  $\text{NH}_3$  and fumaric acid. Combines with bromine (1 mol.). Salts. —  $\text{BaA}'$ , 6aq: plates, sl. sol. water. —  $\text{AgA}'$ : small needles or leaflets, sol. hot water. **Methyl ether**  $\text{A}'\text{Me}$ : [162°]; small colourless tables; sublimable; sl. sol. cold water, v. sol. alcohol. Formed by the action of cold, slightly acidulated, water on methyl diazo-succinamate  $\text{CO}_2\text{Me.CH}_2\text{CN}_2.\text{CO}_2\text{Me}$  (Curtius a. Köth, *B.* 19, 2461).

**Amide**  $\text{C}_4\text{H}_4\text{N}_2\text{O}_6$ , i.e.  $\text{CONH}_2\text{CH}(\text{CONH}_2)\text{CONH}_2$ . [232°]. From fumaric ether and cold aqueous ammonia (Hagen, *A.* 38, 275). Small white needles (Curtius a. Koch, *B.* 18, 1298). Insol. cold, sol. hot water, insol. alcohol. When heated for some time with water it is converted into ammonium fumarate.  $\text{HgO}$  is converted by boiling with its aqueous solution into a white powder  $\text{C}_4\text{H}_4\text{N}_2\text{O}_6.\text{HgO}$  (Dessaignes, *A.* 82, 283).

**Imide?**  $\text{C}_4\text{H}_4\text{N}_2\text{O}_6$ , i.e.  $\text{CH}_2\text{CO} \begin{matrix} \text{CH} \\ \text{CO} \end{matrix} \text{NH} \begin{matrix} \text{CH} \\ \text{CO} \end{matrix} \text{NH}$ ? Formed

by heating acid ammonium malate at 160° to 200° (Dessaignes, *C. R.* 30, 324; Wolff, *A.* 75, 293). White powder; sol. hot cons.  $\text{HClAq}$  and

reppd. by water. By heating for 6 hours with  $\text{HClAq}$  it is converted into aspartic acid. Acid ammonium maleate and fumarate yield on heating to  $180^\circ$  substances resembling this so-called 'fumarimide' (Pasteur, *A. Ch.* [3] 34, 30).

*Di-ethyl-amide*  $\text{C}_2\text{H}_5(\text{CO.NHET})_2$ . [183°]. White scales; may be sublimed (Wallach & Kamenski, *B.* 14, 170).

*Mono-anilide*  $\text{CO}_2\text{H.CH:CH.CO.NHPh}$ . *Fumaranic acid*. [187°]. From the phenyl-imide of maleic acid by treatment with baryta-water at  $85^\circ$  (Anschütz & Wirtz, *Am.* 9, 240; *A.* 239, 137). Formed also when maleic anhydride, dissolved in ether, is mixed with aniline (Anschütz, *B.* 20, 3214). Prisms, sl. sol. water. Converted by alcoholic KOH into potassium fumarate.

*Di-anilide*  $\text{C}_6\text{H}_5(\text{CO.NHPh})_2$ . Formed by the action of aniline upon fumaryl chloride, both being in ethereal solution (Anschütz & Wirtz, *Am.* 9, 236). Minute white needles, browning at  $275^\circ$ , v. sl. sol. ether, sl. sol. alcohol and glacial acetic acid. Heated at  $100^\circ$  with alcoholic KOH it gives aniline and fumaric acid. Takes up Br (1 mol.), forming a white powder; not melted at  $100^\circ$ .

*Di-phenyl-maleic acid*.  $\text{CONPh}_2\text{.CH:CH.CO}_2\text{H}$ . *Di-phenyl-fumaramic acid*. [120°]. Formed by heating fumaric or maleic acid with di-phenyl-amine at  $210^\circ$ ; extracting the product with ether, shaking the ethereal solution with dilute  $\text{NH}_3$ , and pp. by HCl (Piutti, *G.* 16, 22, 133). Small needles; sol. alcohol and conc.  $\text{H}_2\text{SO}_4$ , the solution giving with nitric acid the blue reaction of diphenyl-amine. Decomposed by KOH into fumaric acid and diphenylamine. Unites with Br forming a crystalline product. Its alkaline solution gives a light green pp. with cupric salts.

Formed by heating fumaric or maleic acid with di-phenyl-amine at  $225^\circ$  as long as water is given off (Piutti). Glistening needles, sol.  $\text{HOAc}$ . With conc.  $\text{HNO}_3$  it yields a nitro-compound giving a violet colouration with alcoholic KOH.

*Phenyl-methyl-maleic acid*.  $\text{CONMePh.CH:CH.CO}_2\text{H}$ . [128°]. Formed by heating maleic acid (1 mol.) with methyl-aniline (not more than 2 mols.) at  $150^\circ$  (Piutti, *G.* 16, 24). It is also one of the products of the action of  $\text{NH}_3$  on phthalyl-aspartic acid. Long tabular prisms (containing aq); melting at  $100^\circ$  when hydrated, and at  $128^\circ$  when anhydrous. \*Insol. water, sol. alcohol and ether. Its alkaline salts are very soluble; its silver salt forms small glistening prisms. Its di-bromo-derivative [178°] forms glistening prisms, partly decomposed on recrystallisation.

*Phenyl-methyl-imide?*  $\text{C}_6\text{H}_5\text{.H}_3\text{N}_2$ , i.e.  $\text{CH}_3\text{CO} \diagup \parallel \text{O. [187°]}$ . Formed by heating  $\text{CH}_3\text{C(NMePh)}_2 \diagdown$  maleic acid with methyl-aniline at  $200^\circ$ . It is also one of the products of the action of phenyl-methyl-amine on phthalyl-aspartic acid at  $240^\circ$ . Glistening prisms, sol. hot alcohol and chloroform. When heated with conc.  $\text{HClAq}$  at  $180^\circ$  it yields fumaric acid and methyl-aniline. Br

in chloroform forms a di-bromo-derivative  $\text{C}_{12}\text{H}_{12}\text{Br}_2\text{N}_2\text{O}_2$  [c.  $207^\circ$ ].

*Constitution*.—Inasmuch as both fumaric and maleic acids are dibasic acids formed from maleic acid by elimination of water, and capable of reduction to succinic acid, they ought both to be represented by the formula  $\text{C}_4\text{H}_2(\text{CO}_2\text{H})_2$ . One or both of them would then be  $\text{CO}_2\text{H.CH:CH.CO}_2\text{H}$ . The usual interpretation given to structural formulae will not in this case account for the isomerism, and it will be necessary, if we assign the formula  $\text{CO}_2\text{H.CH:CH.CO}_2\text{H}$  to both maleic and fumaric acid, to consider that the difference in structural formula is one that cannot be represented on a plane surface but only in space. Various attempts have been made to express a difference in structure upon paper. Thus while the formula  $\text{CO}_2\text{H.CH:CH.CO}_2\text{H}$  has commonly been assigned to fumaric acid, maleic acid has been represented by  $\text{CO}_2\text{H.CH.C.CO}_2\text{H}$  (Fittig, *A.* 188, 42; cf. Hübner, *B.* 14, 210), by  $\text{CH}_3\text{C(OH)}_2 \parallel \text{CH}_3\text{C(OH)}_2 \parallel \text{O}$ , and by  $\text{CH}_3\text{C(OH)}_2 \parallel \text{CH}_3\text{C(OH)}_2 \parallel \text{O}$  (Anschütz, *A.* 239, 161; *Am.* 9, 253; W. Roser, *A.* 240, 133). Erlenmeyer, on the contrary, suggests that maleic acid is  $\text{CO}_2\text{H.CH:CH.CO}_2\text{H}$ , while fumaric acid may have the double formula  $\text{CO}_2\text{H.CH:CH.C(OH)} \parallel \text{C(OH).CH:CH.CO}_2\text{H}$

(*B.* 19, 1936), although Raoult's method of determining molecular weights indicates that this is not the case (Paternò, *B.* 21, 2158). Maleic acid is much more prone to react with other bodies than fumaric acid, and this would be represented by the formula  $\text{CO}_2\text{H.CH}_2\text{.C.CO}_2\text{H}$ , containing a divalent carbon atom, and perhaps also by the anhydride formula  $\text{CH}_3\text{C(OH)}_2 \parallel \text{O}$  of Anschütz. Thus maleic acid combines at once with HBr and with bromine, whereas fumaric acid requires to be heated (in the case of Br the products are different). Again acid aniline maleate readily splits off water when its aqueous solution is left to stand for a few days, or when it is boiled, a crystalline pp. of the acid anilide  $\text{CO}_2\text{H.C}_6\text{H}_4\text{.CONHPh}$  being formed; under these conditions the acid aniline fumarate is quite stable (Michael, *B.* 19, 1372). The chemical differences here noted between fumaric and maleic acids hold good also between citraconic and mesaconic acids, and between ( $\alpha$ )-coumaric and ( $\beta$ )-coumaric acids. There is also but one anhydride to each of these pairs of acids. The fact that fumaric acid, on oxidation by  $\text{KMnO}_4$ , gives racemic acid, while maleic acid gives inactive tartaric acid, has been explained by Le Bel by the aid of formulae represented in three dimensions (v. also Lossen, *B.* 20, 3910; Anschütz, *B.* 21, 518). According to Knops (*A.* 248, 175) the molecular refraction of fumaric and maleic acids and their ethers indicates that both these acids contain the group C:C. The term 'allo-isomerism' has been applied to such cases of isomerism as that here described: fumaric acid may be called allo-maleic acid.

*References*.—MALEIC ACID, BROMO-FUMARIC ACID, and CHLORO-FUMARIC ACID.

**FUMARINE**. An alkaloid contained in fumitory (*Fumaria officinalis*) (Peschieur; Hannon,

*J. Chim. Méd.* [3] 8, 705; Preuss, *Z.* [2] 2, 414; *Bl.* [2] 7, 458). The plant gathered in full flower may contain 5 p.c. of fumarine. The plant is extracted by dilute acetic acid at 100°, the extract evaporated, the syrupy residue dissolved in alcohol, and decolourised by animal charcoal. Fumarine acetate crystallises from the alcoholic solution in slender needles. Aqueous KOH and Na<sub>2</sub>CO<sub>3</sub> separate fumarine from its salts as a curdy pp. It crystallises in six-sided irregular monoclinic prisms, sl. sol. water, insol. ether, sol. alcohol, chloroform, benzene, and CS<sub>2</sub>. Its solution has a bitter taste and alkaline reaction. Conc. HNO<sub>3</sub> does not colour it. Conc. H<sub>2</sub>SO<sub>4</sub> forms a dark-violet liquid. Its hydrochloride and sulphate crystallise in prisms, sl. sol. water; its platinumchloride and aurochloride crystallise in octahedra.

*Pyromucic aldehyde.* *Furfural.* *Furfural.* *Furfurane-carboxylic aldehyde* (*Furfur* = bran). Mol. w. 96. (162°) (Brühl, A. 235, 7). V.D. 3.34 (calc. 3.82). S.G.  $\frac{1}{2}$  1.1594 (B.). S. 9 at 13° (Stenhouse); 8.8 at 15.6° (Fownes).  $\mu_D$  1.5261 (B.). S.V. 95.53 (R. Schiff, A. 220, 103); 103 (Ramsay). H.F.p. 5985 (Ramsay, C. J. 35, 703). *Dispersion value:* Brühl, A. 236, 259.

*Occurrence.*—Has been observed in brandy (Morin, C. R. 105, 1019), and is a constant impurity in isoamyl alcohol prepared from fusel oil (Udránsky, H. 13, 248).

*Formation.*—1. A general product of the destructive distillation of the carbohydrates or of substances containing them, such as wood. Formed also in the torrefaction of coffee and cocoa and occurs in tobacco smoke (Völckel, A. 85, 65; Hill, *Am.* 3, 36; H. Schiff, G. 17, 355; Gaus, Stone, & Tollens, B. 21, 2148; V. Meyer, B. 11, 1870; Förster, B. 15, 322; Jorisson, B. 15, 574).—2. By distilling the following substances with dilute sulphuric acid: bran, starch, oatmeal, sugar, madder, sawdust, linseed cake, cocoa-nut shells, mahogany, and even, according to Udránsky (H. 12, 377), of proteids (Doebereiner [1831] *Schw.* J. 68, 368; A. 3, 141; Stenhouse, P. M. [3] 18, 122; 87, 226; A. 35, 301; 74, 278; 156, 197; Fownes, Tr. 1845, 258; A. 54, 52; Ph. 8, 118; Cahours, A. Ch. [3] 24, 277; Emmet, *Am.* S. 82, 140; Gudschoff, Z. 1870, 362; Guyard, *Bl.* [2] 41, 289).—3. By distilling sugar with MnO<sub>2</sub> and dilute sulphuric acid.—4. By heating bran with a very strong solution of ZnCl<sub>2</sub> (Von Babo, A. 85, 100).—5. By heating wood shavings

with water for four hours at 200° (Greville Williams, C. N. 26, 231, 298; H. Müller, C. N. 26, 247).—6. Formed in small quantity by boiling sugar with water; this accounts for its occurrence in brandy (Förster, B. 15, 230, 322). 7. One of the products obtained by heating (a) acetone to 140° (E. Fischer a. Tafel, B. 22, 99). Obtained also by heating a dilute aqueous solution of gluconose in a sealed tube at 140° (E. Fischer, B. 22, 98).—8. By heating a 5 p.c. aqueous solution of mannite in a closed tube for 4 hours at 140° (E. Fischer a. Hirschberger, B. 22, 389).

*Preparation.*—1. By distilling sugar (1 pt.) with MnO<sub>2</sub> (3 pts.), H<sub>2</sub>SO<sub>4</sub> (3 pts.), and water (5 pts.); the distillate is neutralised by Na<sub>2</sub>CO<sub>3</sub>, redistilled, and saturated with CaCl<sub>2</sub> (Doebereiner).—2. H<sub>2</sub>SO<sub>4</sub> (100 pts.), water (300 pts.), and bran (100 pts.) are distilled together. The product is neutralised by Na<sub>2</sub>CO<sub>3</sub>, redistilled, saturated with NaCl and re-distilled (Schwanert, A. 116, 257). The yield is small (less than 3 pts.). The crude furfuraldehyde is treated with dilute H<sub>2</sub>SO<sub>4</sub> and a little K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> to remove 'metafurfural,' dried over CaCl<sub>2</sub>, and rectified.—3. An abundant source of furfuraldehyde is in the preparation of 'garancin' by boiling madder with dilute sulphuric acid.

*Impurity.*—Crude furfuraldehyde is liable to contain a readily oxidisable oil of higher boiling-point, which is for the most part resinified during the distillations. When this 'metafurfural' is present the furfuraldehyde gives a purple colour when mixed with a few drops of conc. H<sub>2</sub>SO<sub>4</sub>, of HClAq, or of HNO<sub>3</sub>; in this case also the aldehyde, after boiling with aqueous KOH, turns red on acidification.

*Properties.*—Colourless oil which, except when quite pure, slowly turns brown when exposed to light. Its odour resembles that of a mixture of the oils of cinnamon and of bitter almonds. It burns with a smoky flame. Furfuraldehyde when present in a liquid imparts a rose-red colour to paper saturated with aniline acetate (Guyard, *Bl.* [2] 41, 289); but its presence is best detected by a mixture of equal volumes of xylidine and glacial acetic acid to which a little alcohol is added when the intense red colour of C<sub>6</sub>H<sub>5</sub>O.CH(C<sub>6</sub>H<sub>5</sub>.Me.NH<sub>2</sub>)<sub>2</sub> is produced: this reaction is exhibited by the product of the distillation of 0.0005 g. sugar (H. Schiff, G. 17, 355; B. 20, 540). Furfuraldehyde may be substituted for sugar in Pettenkofer's reaction; thus a drop of a solution of furfuraldehyde (1 pt.) in water (20,000 pts.) gives a crimson colour on the addition of cholic acid and H<sub>2</sub>SO<sub>4</sub>. The following substances also give the red colour with H<sub>2</sub>SO<sub>4</sub> and furfuraldehyde: isobutyl alcohol, allyl alcohol, *tert*-butyl alcohol, *tert*-amyl alcohol, isoamyl alcohol, oleic acid, petroleum, acetal, aldehyde, aceto-acetic ether, acetone, glycol, malic acid, alizarin, aniline, anthracene, anthraquinone, atropine, benzoic aldehyde, borneol, pyrocatechin, brucine, quinic acid, cholesterolin, cineholin, codeine, coniferin, conine, coumarin, cymene, digitalin, di-methyl-aniline, di-phenyl-amine, gallic acid, cresol, mesitylene, methyl alcohol, methyl-aniline, morphine, naphthalene, (a)-naphthol, orcin, paraffin, phenanthrene, phenol, phenyl-hydrazine, phloroglucin, propionic aldehyde, proto-

catechuic acid, pyrogallol, resorcin, salicylic acid, seotole, stearic acid, strychnine, toluene, thymol, tyrosine, veratrine, and xylene, and (to a slight extent) isopropyl alcohol. The following do not give the red colour: alcohol, propyl alcohol, acetic acid, isobutyric acid, acrolein, benzene, acetamide, acetophenone, alloxan, aspartic acid, benzonitrile, benzoic acid, succinic acid, pyruvic acid, butyric acid, caffeine, quinine, quinoline, quinone, quinoxaline, chloral hydrate, chloroform, citric acid, crotonic acid, cyanamide, dextrin, dulcitol, fumaric acid, lactic acid, glycerin, glycecoll, glycollic acid, uric acid, urea, hippuric acid, isatin, malic acid, maltose, mandelic acid, mannite, methylamine, oxalic acid, phenylene-m-diamine, phenyl-acetic acid, picric acid, piperidine, pyridine, hydroquinone, mucic acid, starch, glucose, tannin, tartaric acid, and cinnamic acid (Mylus, *H.* 11, 492; Udránsky, *H.* 12, 355).

**Reactions.**—1. When its aqueous solution is boiled with Ag<sub>2</sub>O silver is deposited, and silver pyromucate crystallises out of the cooled filtrate.—2. Hot nitric acid forms oxalic acid.—3. Cold conc. H<sub>2</sub>SO<sub>4</sub> dissolves it unaltered and without becoming coloured; carbonisation sets in on heating.—4. Aqueous KOH, even in the cold, forms resinous products. Alcoholic KOH forms pyromucic acid and furfuryl-carbinol (Ulrich, *C. N.* 3, 116; Limpriht, *Z.* [2] 5, 599). 5. Converted into furon C<sub>6</sub>H<sub>4</sub>O<sub>2</sub> by heating with aqueous KCy.—6. When mixed with benzoic aldehyde (1 equivalent) and treated with KCy it gives benzofuron C<sub>12</sub>H<sub>10</sub>O<sub>2</sub>. [139°] (Fischer, *A.* 211, 228).—7. With nitro-ethane and aqueous KOH it gives furfuryl-nitro-ethylene C<sub>10</sub>H<sub>7</sub>O<sub>2</sub>CH:CH.N<sub>2</sub>O<sub>2</sub> [75°] which crystallises in long yellow prisms (Priebs, *B.* 18, 1362).—8. ZnEt<sub>2</sub>, followed by water forms furfuryl-propyl alcohol C<sub>10</sub>H<sub>13</sub>O<sub>2</sub>CH(OH).C<sub>3</sub>H<sub>7</sub> (180°) (Pawlinoff a. Wagner, *B.* 17, 1968).—9. Condenses with acetone in presence of alkalis forming furfuryl-vinyl methyl ketone C<sub>11</sub>H<sub>10</sub>O<sub>2</sub>CH:CH.CO.CH<sub>3</sub>, and di-furfuryl-di-vinyl ketone (C<sub>10</sub>H<sub>8</sub>O<sub>2</sub>CH:CH)<sub>2</sub>CO (Claisen a. Ponder, *A.* 223, 145).—10. By adding aqueous NaOH to mixed aqueous solutions of furfuraldehyde and chloro-acetic-aldehyde there is formed C<sub>10</sub>H<sub>7</sub>O<sub>2</sub>CH:CCl.CH<sub>2</sub>CHO which crystallises in broad yellow needles [79°] sol. hot water, ether, and alcohol. This aldehyde forms a phenyl-hydrazide [157°] and an oxim [165°]; moist Ag<sub>2</sub>O oxidises it to a-chloro-furfuryl-acrylic acid C<sub>10</sub>H<sub>7</sub>O<sub>2</sub>CH:CCl.CO<sub>2</sub>H which crystallises in tufts of white needles [142°]. The a-chloro-furfuryl-acrolein is converted by boiling with sodium acetate and silver oxide into C<sub>10</sub>H<sub>7</sub>O<sub>2</sub>CH:CCl.CH:CH.CO<sub>2</sub>H which forms yellow interlacing needles [168°] (Mehne, *B.* 21, 423).—11. When furfuraldehyde is administered to dogs or rabbits in doses of 5 g. daily little toxic effect is produced; the urine is found to contain pyromucic acid, pyromucuric acid (glycecoll pyromucate) C<sub>11</sub>H<sub>10</sub>NO<sub>2</sub> [165°], and glycecoll furfuryl-acrylate C<sub>11</sub>H<sub>10</sub>NO<sub>2</sub> [215°]. Boiling baryta-water splits up the two last-named compounds into glycecoll and pyromucic or furfuryl-acrylic acids respectively. Fowls are soon killed by taking 1 g. of furfuraldehyde per day; their excreta then contain pyromucocornithuric acid C<sub>11</sub>H<sub>11</sub>N<sub>2</sub>O<sub>2</sub> [186°] (Jaffé a. Cohn, *B.* 90, 2811; 21, 8461).—12. A mixture of pyruvic

acid and aniline dissolved in cold ether or alcohol forms the compound C<sub>10</sub>H<sub>7</sub>N<sub>2</sub>O<sub>2</sub> [185°] which crystallises in needles, insol. water, ether, acids, and alkalis, sl. sol. cold, m. sol. hot, alcohol; v. sol. HOAc. This compound gives off aniline when warmed with acids or alkalis (Doebner, *A.* 242, 284).—13. A mixture of pyruvic acid and aniline in warm alcoholic solution forms furfuryl-quinoline carboxylic acid C<sub>17</sub>H<sub>13</sub>O<sub>2</sub>C<sub>9</sub>NH<sub>2</sub>CO<sub>2</sub>H [210°-215°] (Doebner).—14. Furfuraldehyde may be substituted for benzoic aldehyde in Perkin's reaction. Thus with NaOAc and Ac<sub>2</sub>O it gives furfuryl-acrylic acid.—15. Thioglycollic acid reacts with formation of C<sub>10</sub>H<sub>7</sub>O<sub>2</sub>CH(S.CH<sub>2</sub>CO<sub>2</sub>H)<sub>2</sub> [105°] (Bongartz, *B.* 21, 478).—16. Aqueous ammonia in the cold converts furfuraldehyde in a few hours into 'furfuramide' (C<sub>10</sub>H<sub>7</sub>O<sub>2</sub>CH)<sub>2</sub>N<sub>2</sub> [117°] a crystalline body analogous to hydrobenzamide. Boiling aqueous KOH converts furfuramide into a base, furfurine C<sub>11</sub>H<sub>11</sub>N<sub>2</sub>O<sub>2</sub>.—17. Combines with secondary and primary amines or with 1 mol. of each to form coloured compounds. Thus with mono-methyl-aniline it gives the compound C<sub>10</sub>H<sub>7</sub>O<sub>2</sub>C<sub>6</sub>H<sub>4</sub>NHMe, whose hydrochloride (B.HCl) forms splendid violet crystals [94°] which dissolves to deep-red solutions. With aniline and mono-methyl-aniline it gives C<sub>10</sub>H<sub>7</sub>O<sub>2</sub>{C<sub>6</sub>H<sub>5</sub>.NH<sub>2</sub> / C<sub>6</sub>H<sub>4</sub>.NHMe} With aniline and tolylene diamine it gives (C<sub>10</sub>H<sub>7</sub>O<sub>2</sub>)<sub>2</sub>{C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub> / C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub>}. With aniline and benzidine it gives (C<sub>10</sub>H<sub>7</sub>O<sub>2</sub>)<sub>2</sub>{C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub> / C<sub>12</sub>H<sub>8</sub>N<sub>2</sub>}. The hydrochlorides of these bases crystallise in bronzy metallic crystals which dissolve in alcohol with violet colour. With aniline and amido-benzoic acid or with aniline and naphthylamine-sulphonic acid furfural yields the compounds: C<sub>10</sub>H<sub>7</sub>O<sub>2</sub>{C<sub>6</sub>H<sub>4</sub>.NH<sub>2</sub> / C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)CO<sub>2</sub>H} and C<sub>10</sub>H<sub>7</sub>O<sub>2</sub>{C<sub>6</sub>H<sub>4</sub>.NH<sub>2</sub> / C<sub>10</sub>H<sub>6</sub>(NH<sub>2</sub>)SO<sub>3</sub>H}. With the ammonium salt of di-nitro-amido-phenol (pieramic acid) it gives {C<sub>10</sub>H<sub>7</sub>O<sub>2</sub>}<sub>2</sub>{C<sub>6</sub>H<sub>3</sub>(NO<sub>2</sub>)<sub>2</sub>(NH<sub>2</sub>)(OH)} whose ammonium salt crystallises in glistening golden needles. Weak acids decompose it into its constituents (Schiff, *B.* 19, 847; cf. Stenhouse, *A.* 166, 199). Furfuraldehyde combines directly with one equivalent of *m*-amido-benzoic acid, of amido-salicylic acid, and of amido-cuminic acid forming dichroic needles with neutral properties (Schiff, *A.* 201, 355; *G.* 10, 67). The compound of furfuraldehyde with *m*-amido-benzoic acid may be represented on the rosaniline type thus: C<sub>10</sub>H<sub>7</sub>O<sub>2</sub>CH(OH).C<sub>6</sub>H<sub>3</sub>(CO<sub>2</sub>H)NH<sub>2</sub> (Schiff, *G.* 17, 329).—18. An alcoholic solution of aniline (46 pts.) and aniline hydrochloride (65 pts.) reacts upon furfural (48 pts.) forming the hydrochloride of 'furfuraniline' C<sub>10</sub>H<sub>7</sub>O<sub>2</sub>(NH<sub>2</sub>Ph).HCl (*cf. supra*), which crystallises from alcohol in purple needles, insol. water. The free 'furfuraniline' is an unstable brown amorphous mass.—19. *m*-Nitro-aniline forms C<sub>11</sub>H<sub>10</sub>(NO<sub>2</sub>)NH<sub>2</sub>(C<sub>10</sub>H<sub>7</sub>O<sub>2</sub>) [100°-120°] which crystallises from alcohol in lemon-yellow crusts. Its hydrochloride C<sub>11</sub>H<sub>10</sub>N<sub>2</sub>O<sub>2</sub>.HCl forms copper-coloured plates and gives a crimson solution in alcohol.—20. Diphenylamine (2 mols) at 150° forms a com-

pound whose hydrochloride is copper-coloured and forms a crimson solution in alcohol. Diphenylamine hydrochloride gives the same body.

21. *p*-Amido-phenol in dilute aqueous solution reacts with elimination of water, depositing after some time small yellow prisms of 'oxyfurfuraniline'  $C_6H_4O.CH:N.C_6H_4OH$  [182°] which is sol. alcohol, and forms a hydrochloride that crystallises from alcohol containing  $NH_4Cl$  in a form resembling grosaniline hydrochloride (Schiff, *G.* 10, 60; *A.* 201, 358).—22. *Phenylene-diamine hydrochloride* solution forms  $(C_6H_4O.CH)_2N_2C_6H_4$  [96°] (Ladenburg a. Engelbrecht, *B.* 11, 1653).—23. *Tolylene-m-diamine* forms  $(C_6H_4O)_2C_6H_4Me(NH_2)_2$ , a crystalline substance, decomposed at 125° without melting. Its hydrochloride forms an intense crimson solution in alcohol, but is much less stable than the corresponding compound with tolylene-o-diamine (Schiff; cf. Ladenburg, *B.* 11, 595).—24. *Benzidine* in alcoholic solution forms yellow needles of  $(C_6H_4O.CH:NH)_2C_6H_4$ ; which gives a hydrochloride crystallising in copper-coloured scales, and a platinum chloride separating as a yellow crystalline powder.—25. When triturated with *m*-amido-benzoic acid it combines to form  $(C_6H_4O)_2C_6H_4(NH_2).CO_2H$  which crystallises in small dichroic scales resembling a salt of rosaniline. Its hydrochloride forms red velvety crystals and gives crimson solutions in alcohol and  $HOAc$ . It dissolves in  $Na_2CO_3$  aq without evolution of  $CO_2$ .—26. A mixture of *aniline hydrochloride* and *methyl-aniline* give a ruby-red colouration turning green and finally violet; the body formed in this reaction  $C_6H_4O_2(NH_2Ph)(NHMePh)HCl$  is a crystalline mass, v. sol. alcohol, insol. water.—27. (β)-*Naphthylamine* forms, with elimination of water,  $C_6H_4O.CH:N.C_{10}H_7$  [85°]. It crystallises from alcohol in colourless scales. Its hydrochloride  $BHCl$  forms yellow needles dissolving in alcohol with a deep red colour (Schiff, *G.* 17, 340).—28. *Di-methyl-aniline* and  $ZnCl_2$  heated with furfuraldehyde form  $C_{11}H_{12}N_2O$  [83°] which crystallises from ligroin in needles. It forms a crystalline platinum chloride  $B''H.PtCl_6$  and picrate  $B''(C_6H_4(NO_2)_2)OH$  (Fischer, *A.* 206, 141).—29. (Py.3)-*Methyl-quinoline* heated with an equivalent of furfuraldehyde at 100° together with a small quantity of  $ZnCl_2$  forms a base  $C_{15}H_{11}NO$  which crystallises from ligroin in needles or tables that turn black in daylight. Its salts  $B'HCl$ ,  $B'HNO_3$ ,  $B'H_2SO_4$  aq,  $B''H_2PtCl_6$  2aq, and  $B''C_6H_4(NO_2)_2OH$  are crystalline (Srpek, *B.* 20, 2044).—30. *Carbamic ether* in presence of  $HCl$  forms  $C_6H_4O.CH(NH.CO_2Et)$ , [169°] which may be sublimed as long thin needles, insol. water, v. e. sol. alcohol and ether (Bischoff, *B.* 7, 1081).—31. A solution of *urea nitrate* is coloured violet by furfuraldehyde and the solution gradually deposits a black substance (Schiff, *B.* 10, 773).—32. *Ammonium sulphide* forms thiofurfuraldehyde  $C_4H_4O.SHS$  (Cahours, *A. Ch.* [3] 24, 281), which is a yellow crystalline powder. When heated thiofurfuraldehyde gives off an unpleasant odour and yields a sublimate of a polymeride of furfuraldehyde [98°] (Schwanert, *A.* 184, 61).—33. With benzil and alcoholic  $NH_3$  it forms two compounds of the formula  $C_{12}H_{12}N_2O_2$  [246°] and [above 800°] (Japp a. Hooker, *C. J.* 45, 684).—34. With phenanthraquinone and

$NH_3$  it gives  $C_6H_4O \begin{smallmatrix} \diagup O \\ \diagdown N \end{smallmatrix} C_6H_4O$  [231°] (Japp a. Wilcock, *C. J.* 39, 217).

**Combination.**  $C_6H_4O.CH(OH).SO_3Na$ . Formed by adding alcohol to a solution of furfuraldehyde in conc.  $NaHSO_4$  aq. White laminae, with fatty lustre.

*Oxim*  $C_6H_4O.CH:NOH$ . [89°]. (201°–208°). Formed by the action of hydroxylamine (base) on furfuraldehyde (Oderheimer, *B.* 16, 2988). Long thin white needles. By heating with  $HCl$  it is resolved into its constituents. Salts.— $C_6H_4O.NOH.HCl$ : white crystalline powder, sol. water and alcohol.— $C_6H_4O.N(ONa)_3$  3aq: white scales. It gives characteristic pps. with the salts of the heavy metals.

*Ethyl ether*  $C_6H_4O.N(OEt)$ : colourless liquid, volatile with steam, lighter than water, in which it is slightly soluble.

*Phenyl hydrazide*  $C_6H_4O.CH:N.NHC_6H_5$ . [98°]. Formed by adding a solution of phenylhydrazine hydrochloride (*q. v.*) and sodium acetate to an aqueous solution of furfuraldehyde; 1 pt. of furfuraldehyde in 10,000 pts. of water gives a distinct crystalline pp. (Fischer, *B.* 17, 574). Fine colourless plates. Insol. water, sol. ether, from which solution it is ppd. in crystals by adding ligroin.

*Di-phenyl-hydrazide*  $C_6H_4O.CH(NPh)_2$ . [59°] (Cornelius a. Homolka, *B.* 19, 2240).

**FURFURAMIDE**  $C_5H_7N_2O_2$  i.e.  $(C_4H_5O)_2N_2$ . [117°]. Formed as a crystalline mass by allowing furfuraldehyde to stand for some hours with (5 times its volume of) conc.  $NH_4$  aq (Fownes, *Tr.* 1845, 253; *A.* 54, 55; R. Schiff, *B.* 10, 1188). Tufts of needles (from alcohol). Insol. cold water, v. sol. alcohol and ether. When heated with water it is slowly resolved into ammonia and furfuraldehyde; this change is instantly produced by acids.  $H_2S$  yields thiofurfuraldehyde (*v. supra*). Boiling dilute  $KOH$  converts furfuramide into the isomeric furfurine. When heated with an alcoholic solution of phenyl thiocarbimide it forms a crystalline compound  $C_{12}H_{11}N_3SO_2$ , insol. water, sl. sol. cold alcohol.

**FURFURANE**  $C_5H_6O$ . *Furane*. *Tetra-phenol*. *Tetrol*. *Tetrane*. (31°). V.D. 2.4. S.G. 2.964; 13.944. Formed by distilling barium pyromucate with soda-lime (Rohde, *B.* 3, 90; Limpricht, *A.* 165, 281). Formed also by the action of  $PCl_5$  on its dihydride. The product is washed with  $KOH$  aq, dried by  $K_2CO_3$ , and rectified (Henninger, *A. Ch.* [6] 7, 222). It is a liquid. Unacted upon by  $KHO$ , aniline, or hydroxylamine. Colours pine-wood moistened with  $HCl$  emerald green (Canzonero a. Oliveri, *G.* 16, 490).  $HCl$  converts it into a yellow-black compound.  $PCl_5$  forms with it a black compound. With  $Br$ ,  $C_6H_5OBr$ , and  $C_6H_5OBr_2$  [5°] (65°) at 30 mm. are formed.

Furfurane dihydride  $C_5H_8O$ . (67°). S.G. 2.967; 12.95. V.D. 2.35.

**Preparation.**—A product of the action of formic acid on erythrite. Separated from the crotonic aldehyde, which is also formed, by fractional distillation (Henninger, *A. Ch.* [7] 7, 218).

**Properties.**—Very stable liquid; does not blacken nor polymerise. Forms a dibromide  $C_5H_6Br_2O$ . [12°]. (95° at 80 mm.). Yields furfurane (31°) when heated with  $PCl_5$ . Conc.  $HCl$

and yellow phosphorus give *sec*-butyl iodide (120°).

**DERIVATIVES OF FURFURANE.**—Furfurane ( $C_4H_4O$ ) is the oxygen analogue of thiophene ( $C_4H_4S$ ) and pyrrole ( $C_4H_5NH$ ), and all three compounds are doubtless constituted in an analogous manner. Since in their reactions they resemble benzene and its derivatives rather than the fatty group, it is generally held that their molecules should be represented by ring formulae. When pyromucic acid is distilled with lime and ammonia-zinc chloride, it yields pyrrole, as well as furfurane. In this reaction we may suppose the O of the furfurane directly displaced by NH (Canzoneri & Oliveri, *G.* 16, 486). When a mixture of pyromucic acid, aniline, and  $ZnCl_2$  is heated ( $\alpha$ )-naphthylamine is produced. In this reaction the (nascent) furfurane acts (like an alcohol, phenol, or glycide) as if it were the anhydride of the alcohol  $CH(OH):CH:CH:CH(OH)$ , the reaction being:

(C. a. O.). As another instance of the analogy of furfurane with thiophene and pyrrole, we may take the condensation of acetophenone-acetone  $Ph.CO.CH_2.CH_2.CO.Me$  or the alternative  $Ph.C(OH):CH:CH:CH(OH).Me$ , which by treatment with  $P_2O_5$  loses  $H_2O$ , giving phenyl-methyl-

furfurane  $\begin{array}{c} CH-HC \\ | \\ MeC-O-CPh \\ | \\ CH-HC \end{array}$ . In an analogous manner, when heated with  $P_2S_5$ , it gives phenyl-methyl-thiophene  $\begin{array}{c} CH-HC \\ | \\ MeC-S-CPh \\ | \\ CH-HC \end{array}$ ; and with alcoholic  $NH_3$  it gives phenyl-methyl-pyrrole  $\begin{array}{c} CH-HC \\ | \\ MeC-NH-CPh \\ | \\ CH-HC \end{array}$  (Paal, *B.* 18, 367). Just as

$MeC-NH-CPh$  yields a furfurane derivative by condensation, so acetyl-acetone  $MeCO.CH_2.CH_2.CO.Me$ , di-acetyl-succinic ether  $Me.CO.CH(CO.Et).CH(CO.Et).CO.Me$ , acetyl-aceto-acetic ether  $Me.CO.CH_2.CH(CO.Et).CO.Me$ , and di-tolyl-ethylene  $C_6H_4.CO.CH_2.CH_2.CO.C_6H_4$  yield corresponding derivatives of furfurane. Diketones of the form  $RCO.CR'(OH).CH_2.CO.R''$  and  $R.CO.CR':CH.CO.R''$  yield on reduction fur-

furane derivatives  $\begin{array}{c} RC \quad CH \\ | \quad | \\ RC-O-CR' \end{array}$  (Jappa & Klingemann, *B.* 21, 2932).

Furfurane being analogous to benzene, the radicle  $C_4H_3O$  will resemble phenyl in its general character. Baeyer proposed to call this radicle 'furfur'; but it is called *furfuryl* in this Dictionary.

**FURFURINE**  $C_4H_4O.N_2$  [116°]. *S.* 75 at 100°; 0.21 at 8°.

**Preparation.**—Furfuraldehyde, obtained by distilling bran with dilute  $H_2SO_4$ , is converted by strong  $NH_3$  into furfuranide. Furfuranide is boiled with very dilute  $KOH$  for 10 minutes, on cooling furfurine separates as slender needles. These are boiled with excess of oxalic acid, the solution is decolourised by animal charcoal and allowed to crystallise. The acid oxalate then separates. It is decomposed by  $NH_3$  (Bahrman, *J. pr.* [2] 27, 311; cf. Fownes, *Tr.* 1845, 253; Stenhouse, *A.* 74, 289; Svanberg & Bergstrand, *J. pr.* 66, 239; Bertagnini, *A.* 88, 128).

**Properties.**—Soft white silky needles. Permanent in the air when dry, but turns brown when exposed to moist air. *Sl.* sol. water, *v. e.* sol. alcohol and ether. Its solutions exhibit alkaline reaction.

**Reactions.**—1. **Acetyl chloride** added to an ethereal solution of furfurine appears to form a molecular compound, which, however, is decomposed by alcohol into furfurine hydrochloride and acetyl furfurine, thus:  $2C_4H_4O.N_2 + AcCl = C_4H_4O.N_2.HCl + C_4H_4O.AcO.N_2$ .—2. **Benzoyl chloride** appears also to form an unstable molecular compound, it is decomposed by warm alcohol, and the product may be  $C_4H_4O(OEt)BzO.N_2$ .—3. **Chloroformic ether**,  $ClCO_2Et$ , added to an ethereal solution of furfurine, forms furfurine carboxylic ether:  $C_4H_4O(CO_2Et)O.N_2$  [124°] (Bahrman, *J. pr.* [2] 27, 311).—4. **Furfurine** separates iodine from aqueous periodic acid (Bodeker, *A.* 71, 64).—5. A very dilute solution of  $KNO_3$  added to one of furfurine sulphate, gives a pp. of the nitrosamine  $C_4H_4O(NO)N_2O$ , which separates from ether in golden triclinic crystals [112°] insol. water, *m. sol.* alcohol and ether (R. Schiff, *B.* 11, 1250). But if the solution of furfurine sulphate be not very dilute, a compound  $C_4H_4O.N_2O$ , [95°] separates after some time. This is yellow and crystalline, and is also formed by saturating an alcoholic solution of furfurine sulphate with nitrous gas. It is insol. water and ether, *v. sol.* alcohol, and forms a platinumchloride  $(C_4H_4O.N_2O)_2PtCl_6$ .

**Salts.**—Furfurine expels  $NH_3$  from boiling aqueous  $NH_4Cl$ , but is itself ppd. by  $NH_3$  from its salts in the cold. The salts of furfurine have an extremely bitter taste. They are ppd. by  $HgCl_2$  and by  $H_2PtCl_6$ .—*B'HClaq.*: tufts of silky needles, *v. sol.* water, *m. sol.*  $HCl$ aq. Neutral in reaction. Does not effloresce over  $H_2SO_4$ .—*B'H\_2PtCl\_6*: long light-yellow needles.—*B'HI*aq.: slender, oblique, four-sided prisms. *S.* 18 in the cold.—*B'HBraq.*: short prismatic needles. *S.* 3-9 (Davidson, *Ed. N. Phil. J.* [3] 2, 284).—*B'H\_2CrO\_4*: orange-yellow powder, *sl. sol.* cold water (*D.*).—*B'ONO*: trimetric prisms (from alcohol).—*B'HCIO\_4*aq.: long thin trimetric

prisms [ $150^{\circ}$ – $160^{\circ}$ ]. Effloresces at  $60^{\circ}$ . V. sol. water and alcohol (Bödeker, *A.* 71, 63; Dauber, *A.* 71, 67).— $B'H_2SO_3 \cdot 3aq$ : prisms, v. sol. water, m. sol. alcohol and ether, sl. sol. dilute  $H_2SO_4$ . Efflorescent.— $B'H_2PO_4$ : four-sided trimetric laminae. [ $200^{\circ}$ – $215^{\circ}$ ]. V. sol. hot water and alcohol, insol. ether.— $B'H_2PO_4$ : glittering, oblique, four-sided prisms: v. sol. boiling water and alcohol, nearly insol. ether. Neutral in reaction.— $B'H_2PO_4$ : long, oblique, four-sided prisms without lustre; permanent in the air; v. sol. water and alcohol, sl. sol. ether. Has an alkaline reaction.— $B'H_2P_2O_7 \cdot aq$ : glassy crystalline crust; v. sol. water and alcohol; neutral in reaction.— $B'H_2C_2O_4$ : thin tables, v. sl. sol. cold water.

**Acetyl derivative**  $C_{11}H_{11}AcN_2O_4$  (c.  $250^{\circ}$ ). From furfural and  $Ac_2O$  by gently warming (R. Schiff, *B.* 10, 1188). White flocculent micro-crystalline mass (from boiling alcohol). Insol. water, m. sol. alcohol and ether. Not saponified by boiling aqueous KOH. Does not combine with acids. With bromine in  $HOAc$  it forms a hexabromide  $C_{11}H_{11}Br_6AcN_2O_4$  which is ppd. on adding water.

**Ethyl-furfurine**  $C_{11}H_{11}EtN_2O_4$ . The hydriodide is formed by heating an alcoholic solution of furfural with  $EtI$  at  $100^{\circ}$  (Davidson). It separates by evaporation of the cold alcoholic solution in prisms. S. 2-8. M. sol. alcohol and ether. Moist  $Ag_2O$  converts it into a syrupy alkaline hydriodide which forms a platinochloride  $(C_{11}H_{11}EtN_2O_4)_2H_2PtCl_6$ .

**Isoamyl furfuraline**  $C_{11}H_{11}(C_4H_9)_2N_2O_4$ . The hydro-iodide prepared by heating furfural with isoamyl iodide is a radio-crystalline mass. The platinochloride  $B'H_2PtCl_6$  is a yellow powder, sl. sol. water.

**FURFUR-BENZIDINE** v. FURFURALDEHYDE, Reaction 23.

**FURFUBOL** v. FURFURALDEHYDE.

**FURFUR-( $\beta$ )-NAPHTHYLAMINE** v. FURFURALDEHYDE, Reaction 26.

**FURFURONITRILE** v. *Nitrile* of PYROMUCIC ACID.

**FURFURYL-ACROLEIN** v. FURFURYL-ACRYLIC ALDEHYDE.

**FURFURYL-ACRYLIC ACID**  $C_6H_5O_4$ , i.e.  $C_6H_5O.CH:CH.CO_2H$ . *Furfuracrylic acid*. [ $136^{\circ}$ ]. S. 2 (in the cold). Formed, by Perkin's reaction, by heating furfuraldehyde (1 pt.) with  $NaOAc$  (2 pts.) and  $Ac_2O$  (2 pts.) at  $250^{\circ}$  for 11 hours; the solution solidifies on cooling, and after dissolving in  $Na_2CO_3$  aq. the acid is ppd. by  $HCl$ . The yield is 80 p.c. of the theoretical (Baeyer, *B.* 10, 355; Marckwald, *B.* 20, 2811). Formed also by oxidation of the corresponding aldehyde, furfuryl-acrylic aldehyde, by  $Ag_2O$  (J. G. Schmidt, *B.* 18, 2344). Formed, together with glycol, by the action of boiling baryta-water on furfuryl-acrylic acid, which is in the urine of dogs that have taken furfuraldehyde (q.v.). Long white needles (from water); volatile with steam. The  $Ag$  salt is m. sol. hot water.

**Reactions**.—1. Reduced by sodium-amalgam to furfuryl-propionic acid.—2. Bromine acting on furfuryl-acrylic acid forms crystalline  $C_6H_5BrO_4$ , which is decomposed by water into di-bromo-furfuryl-ethylene and  $CO_2$  (Hill, *B.* 20, 8359).—3. When furfuraldehyde is heated with 95 p.c. alcohol (8-5 pts.) and saturated with  $HCl$  there is formed an ether  $C_6H_5O(CO_2Et)_2$

( $286^{\circ}$ ), possibly  $(CO_2Et.CH_2CH_2)_2CO$  (since it forms a phenyl hydrazide [ $115^{\circ}$ ] and an oxim [ $38^{\circ}$ ]); it is a heavy oil, and the corresponding acid forms thin prisms [ $138^{\circ}$ ], and has a crystalline silver salt. The acid  $C_6H_5O(CO_2H)_2$  does not combine with  $Br$ , is not reduced by sodium-amalgam, and yields succinic acid when oxidised by  $HNO_3$  (Marckwald, *B.* 20, 2811; 21, 1398). The acid ether  $C_6H_5O(CO_2H)(CO_2Et)$  [ $68^{\circ}$ ] forms a crystalline oxim [ $112^{\circ}$ ].

**Ethylether**  $EtA'$ . ( $229^{\circ}$ ). Oil.

**$\alpha$ -Chloro-furfuryl-acrylic acid**

$C_6H_5O.CH:CCl.CO_2H$ . [ $142^{\circ}$ ]. Prepared by digesting  $\alpha$ -chloro-furfuryl-acrolein with  $Ag_2O$ .

**Properties**.—Rosettes of white crystals, sol. hot water, alcohol, ether, benzene, and chloroform, insol. light petroleum. It agglomerates before melting. Conc.  $H_2SO_4$  gives a red colour changing to yellow on dilution.

**Salts**.— $Cu$  salt is a greenish pp. dissolving in ammonia with blue colour.— $Pb$  and  $Hg$  salts are white pps., sol. hot water.— $Fe$  salt is a red-brown pp.— $Zn$  salt a white gelatinous pp.—Alkaline and alkaline earth salts are v. sol. water (P. Mehne, *B.* 21, 426).

**FURFURYLACRYLIC ALDEHYDE**  $C_6H_5O_4$ , i.e.  $C_6H_5O.CH:CH.CHO$ . [ $51^{\circ}$ ]. (above  $200^{\circ}$ ). Prepared by the action of aldehyde or paraldehyde and aqueous KOH on furfural (Schmidt, *B.* 13, 2342). Very volatile with steam. Long colourless needles. V. sol. hot, sl. sol. cold, water.

**Reactions**.—With aniline dissolved in acetic acid it gives an intense green colouration. Reduces  $Ag_2O$  forming furfuryl-acrylic acid.

**$\alpha$ -Chloro-furfuryl-acrylic aldehyde**

$C_6H_5O.CH:CCl.CHO$ . [ $79^{\circ}$ ]. From furfuraldehyde, chloro-acetic aldehyde, and aqueous  $NaOH$  (Mehne). Broad yellow needles, sol. hot water, ether, and alcohol. Forms a phenyl-hydrazide [ $157^{\circ}$ ] and an oxim [ $165^{\circ}$ ].

**FURFURYLAMINE** v. FURFURYL-CARBINYL AMINE.

**FURFURYL-ANGELIC ACID**  $C_6H_5O_4$ , i.e.  $C_6H_5O.CH:Cet.CO_2H$ . [ $88^{\circ}$ ]. Formed by gradually heating furfuraldehyde with *n*-butyric anhydride and sodium *n*-butyrate in an open vessel to  $180^{\circ}$  (Baeyer, *B.* 10, 1364; Tönnies, *B.* 12, 1200). Silky needles (from hot water). Reduced by sodium-amalgam to furfuryl-valeric acid.

**FURFURYL-BUTYLENE**  $C_6H_5O.CH:C(CH_3)_2$ . [ $153^{\circ}$ ]. V.D. = 4.27. S.G.  $\frac{4}{4} = 9509$ . Prepared by cobobating a mixture of furfuraldehyde (3 pts.), isobutyric anhydride (7 pts.) and fused sodium acetate (4 pts.) for twelve hours. Sodium isobutyrate used instead of acetate gives the same product.

**Addition product with  $N_2O_4$** .— $C_6H_5O_4N_2$ . [ $94^{\circ}$ ]; large glistening tables; easily soluble in ordinary solvents. It decomposes at  $145^{\circ}$ – $150^{\circ}$  into its constituents. On reduction with tin and  $HCl$  it gives a mixture of furfurylbutylene oxide  $C_6H_5O.CH:O(CH_2)_3$  (a liquid ( $186^{\circ}$ ), sol. water

and volatile with steam) and amido-furfurylbutylene oxide (q.v.)  $C_6H_5O.C(NH_2).O(CH_2)_3$  (Tönnies a. Staub, *B.* 17, 851; cf. *B.* 11, 1511).

**FURFURYL-CARBINOL**  $C_5H_6O_2$ , *i.e.*

$C_5H_6O_2 \cdot CH_2OH$ . Formed by reducing furfuraldehyde with sodium-amalgam (Beilstein a. Schmelz, *A. Suppl.* 3, 275). Formed also, together with pyromucic acid, by the action of alcoholic KOH on furfuraldehyde (Limprihit, *Z.* [2] 5, 599). Syrup drying up to an amorphous resin; cannot be distilled. HClAq colours it green. Gives succinic acid, HOAc, formic acid, and  $CO_2$  on fusion with KOH. Aniline added to its aqueous solution gives a yellow flocculent pp. of  $C_{11}H_{11}NO$ . Aniline hydrochloride added to its alcoholic solution ppts. reddish-green scales of  $C_{11}H_{11}NO \cdot NH_4PhCl$  (H. Schiff, *B.* 19, 2154).

**FURFURYL-CARBINYL-AMINE**

$C_5H_6O \cdot CH_2NH_2$ , (146°) (C. a. D.); (185°) (T.). V.D. = 49.1 (obs.). Prepared by reduction of pyromuco-nitrile with zinc and dilute  $H_2SO_4$ . The product is distilled with steam, the distillate acidified and evaporated to a small bulk; on adding solid KOH the base separates (Ciamician a. Dennstedt, *B.* 14, 1475; *G.* 11, 332). Obtained also by reducing the phenyl-hydrazide of furfuraldehyde (45 g.) dissolved in alcohol (600 g.) with  $2\frac{1}{2}$  p.c. sodium-amalgam (1350 g.) in the cold (below 8°) (Tafel, *B.* 20, 398). Liquid. Miscible with water. Strong smell. Powerful base. Absorbs  $CO_2$  from the air forming a crystalline mass [75°].

Salts.—B'HCl: colourless soluble prisms or needles. (B'HCl) $_2$ PtCl $_4$ : orange-yellow trimetric plates, soluble in hot water, sparingly in cold.—B' $H_2C_2O_4$  $\frac{1}{2}$ aq: narrow scales.—The sulphate forms minute needles.—The picrate forms golden prisms decomposing at 150° without fusion.

**FURFURYL-CROTONIC ACID**  $C_5H_6O_3$ , *i.e.*  $C_5H_6O \cdot CH:CH \cdot CO_2H$ . [107°]. Formed by oxidising the corresponding aldehyde with  $Ag_2O$  (J. G. Schmidt, *B.* 14, 575). Glittering plates (from hot water) or slender needles (by sublimation). Conc.  $H_2SO_4$  forms with it a red solution.

**FURFURYL-CROTONIC ALDEHYDE**

$C_5H_6O$ , *i.e.*  $C_5H_6O \cdot CH:CH \cdot CHO$  (?) (120° at 110 mm.). Prepared by adding NaOH to an aqueous solution of propionic aldehyde and furfuraldehyde (J. G. Schmidt, *B.* 14, 574). Colourless liquid. Volatile with steam. Gives a green colouration with aniline and acetic acid, and a yellow passing into violet with magenta decolourised with  $SO_2$ . By  $Ag_2O$  it is oxidised to furfuryl-crotonic acid.
